of China), 2. *National Cheng Kung University, Institute of Gerontology, College of Medicine, National Cheng Kung University, Tainan, Taiwan (Republic of China)*

Objective measure of lifestyle of the older adults living in the community is void in the literature. To obtain both objective and subjective measurements to ascertain mobile and day and night lifestyle of older adults living in the community, and to build lifestyle model of older adults in the community by sociodemographic character. This study is a cross-sectional research. 200 over-50-year older adults who own smartphone and live in southern Taiwan were interviewed. Wrist accelerometers to detect behavioral circadian rhythm, GPS app in smartphone to survey mobility, and questionnaire to assess psychological and social status. Preliminary finding of six participants (2 men and 4 women) was analyzed. Data show that participants about 60 years old have large discrepancies in comparison with participants in their 50s: lower sleep efficiency (73 vs 83), earlier Most active 10 hour midpoint (11.48vs 14.13 hour), higher interdaily variability (0.84 vs 0.75), wake after sleep onset (100.39vs 47.78 minutes), and higher exercise frequency (4.33 vs 1.66 times per week). In addition, men have more chronic disease, bigger waistline (103.5 vs 77.5 cm), higher BMI (30 vs 22.5), lower middle to vigorous physical activity time (39 vs 79 minutes), and more total sleep time (356 vs 317 minutes). Age and sex seem to be significant factors determining lifestyle of older adults. Other sociodemographic parameters will be further analyzed.

STANDARDIZED SELF-REPORT TOOLS IN GERIATRIC MEDICINE PRACTICE: A QUALITY IMPROVEMENT STUDY

Melissa Northwood,¹ George Heckman,² Nicole Didyk,¹ Sophie Hogeveen,¹ and Amanda Nova,² 1. *McMaster University, Hamilton, Ontario, Canada*, 2. *University of Waterloo, Waterloo, Ontario, Canada*

Comprehensive geriatric assessment (CGA)—a multidimensional diagnostic process to determine medical, cognitive, and functional capacity—has historically included a narrative history supplemented by use of tools to assess domains such as mood or cognition based on assessor preference. This approach to CGA likely works to assess individuals but with increasing clinical complexity and frailty among older adults, a non-standardized approach may mean that key issues are not assessed, and program quality cannot be determined. The COVID-19 pandemic added to these challenges as social distancing practices meant limited face-to-face appointments and use of phone and video assessments. This quality improvement study implemented the interRAI Check-Up Self-Report instrument through a software platform in a specialized geriatric services practice. The instrument can be used over the phone and summarizes specific health problems and needs as well as information about caregiver status and financial trade-offs. Focus groups were also conducted with specialized geriatric services interprofessional team to explore their experiences with implementation. The descriptive analysis of the self-report data revealed expected geriatric issues, such as cognitive and functional impairment, falls and pain. Clients were also commonly experiencing medical instability, cardiorespiratory symptoms, communication impairments, and elevated risk for emergency department visit.

Staff found the self-report tool feasible, easy to use, efficient, and the program-level metrics helpful for program planning. In conclusion, introduction of a standardized self-report enhanced CGA by creating a systematic method to flag, track, and prioritize all areas of need for immediate and future care planning at both the client and program level.

TECHNOLOGY FOR HEALTHY AGING: USE OF ELECTRONIC COMMUNICATION AMONG OLDER ADULTS

Rumei Yang,¹ Yan Du,² Haocen Wang,³ Zuoting Nie,⁴ Chumin Ji,⁵ and Yun Jiang,⁶ 1. *Nanjing Medical University, Nanjing, Jiangsu, China (People's Republic)*, 2. *School of Nursing, University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States*, 3. *Texas A&M University, College Station, Texas, United States*, 4. *School of Nursing, Nanjing, Jiangsu, China (People's Republic)*, 5. *School of Nursing, Nanjing Medical University, Nanjing, Jiangsu, China (People's Republic)*, 6. *University of Michigan, Ann Arbor, Michigan, United States*

In the digital era, many electronic platforms have been established to facilitate patient-provider communication, such as e-mail, text messaging, and patient portal. The use of these electronic platforms is termed as electronic-communication (e-communication). E-communication has a variety of personalized healthcare functions, such as exchanging information, reviewing lab results, and facilitating patient engagement. However, little is known about the actual use of e-communication among older adults who are potentially major users of e-communication considering their high-level health care needs. Understanding their use of e-communication is critical in improving the application of e-communication in older adults. Using data from American Health Information National Trends Survey (HINTS2019-Cycle3; n=1,961; meanage =74.10, range=65-98), we explored: 1) the prevalence of e-communication use among older adults, and 2) factors affecting their use of e-communication. Variables were measured by self-reports. Weighted logistic regression with replicate weights provided by the HINTS was performed for data analysis. We found that 50% older adults reported the use of e-communication in the last year. Factors associated with higher likelihood of older adults' e-communication use included younger age (OR=09.96, 95%CI=0.93-0.98, p<0.001), higher education (OR=4.82, 95%CI=2.32-10.02, p<0.001 for college graduate or higher), higher income (OR=1.58, 95%CI=1.05-2.38, p=0.030), comorbid conditions (OR=1.64, 95%CI=1.02-2.64, p<0.001), and having a regular provider (OR=2.06, 95%CI=1.31-3.22, p=0.002). This study provided nationally representative results demonstrating a great potential use of e-communication in older adults. Special attention is needed to focus on socially vulnerable older adults (e.g., those with older age, lower education and income, and having comorbidity).

TELEMEDICINE UPTAKE IN A GERIATRIC ASSESSMENT CENTER DURING THE COVID CRISIS

Noelle Frye,¹ Margaret Doyle,² and Richard Marottoli,³ 1. *Yale New Haven Health System, Yale New Haven Health System, Connecticut, United States*, 2. *Yale University, Yale University, Connecticut, United States*, 3. *Yale University, New Haven, Connecticut, United States*

The Yale New Haven Hospital Adler Geriatric Assessment Center is an outpatient consultative service that provides comprehensive assessment of older adults. As elsewhere, at Adler the COVID crisis necessitated a rapid shift in mode of care following a total cessation of in-person visits from late March 2020 to the end of May 2020. While our patients initially preferred telephone visits, video visits as a proportion of total scheduled increased from an average of 6% in the last full week of March to 24% in the last week in May possibly indicating increasing familiarity and comfort with the technology during that time. In addition, while video appointments as a proportion of total scheduled dropped rapidly in June 2020 as face-to-face appointments were re-introduced, we found a steady increase in the proportion of video visits from 3% in the first week of July 2020 to 7% in the second week of February 2021. To test for significance, we ran logistic regression models modelling the dichotomous video-appointment variable as the outcome and week and day of week as continuous variables. We found there was a significant increase in the proportion of appointments delivered over video both during the time when no face-to-face video appointments were allowed (OR=1.21, CI=1.13,1.30) and later in the pandemic (OR=1.04, CI=1.02,1.06). Durbin-Watson statistics were run to ensure that autocorrelation could be ignored. Sensitivity analyses limiting the sample to those with non-cancelled appointments gave similar results. Future analyses will examine patient clinical and demographic characteristics that might influence these trends.

THE 4MS OF AGE-FRIENDLY CARE: SUCCESSFUL INFUSION INTO ELECTRONIC MEDICAL RECORDS LEADS TO IMPROVED CARE

Leah Tobey, and Robin McAtee, *University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*

Electronic Medical Records (EMR) and Health Information Technology (HIT) have changed the daily operations of the healthcare industry. For primary care systems/clinics, it has meant the purchase and tailoring of systems to fit specific needs of users and patients. As one of the HRSA funded Geriatric Workforce Enhancement recipients, the AR Geriatric Education Collaborative (AGEC) worked with a rural federally qualified healthcare clinic system for over a year to help them become IHI certified in Age-Friendly Care and the EMR has been a critical link. The system was crucial in identifying compliancy to the clinical Merit-based Incentive Payment System (MIPS) measures which helped identify the areas where most improvement was needed. Included in the process was a new geriatric screening tab in the EMR system. This tab contains 8 screenings including: depression, anxiety, alcohol use, prescription opioid use and recreational drug use, mentation, medication and mobility. This is in addition to asking "what matters" so that all four of the 4M's age friendly framework components were included. Clinicians are successfully using the systems and improvements in outcomes are beginning to be noted. The outcome MIPS measures are obtained quarterly from an EMR report and data is shared with the staff and new quality improvement projects are developed using PDSA (plan, do, study, act) cycles based on the outcomes of the data. Next steps with the EMR will be the development of flags that will notify the clinicians when a screening is needed.

THE DIGITAL DIVIDE AMONGST HIGH-NEED HIGH-RISK VETERANS

Shirley Li,¹ Kiranmayee Muralidhar,² Fei Tang,³ Willy Marcos Valencia,⁴ and Stuti Dang,⁵ 1. *University of Miami Miller School of Medicine, Boynton Beach, Florida, United States*, 2. *University of Miami Miller School of Medicine, Miami, Florida, United States*, 3. *Miami Veteran Affairs Healthcare System, Miami, Florida, United States*, 4. *Medical University of South Carolina, Miami, Florida, United States*, 5. *Miami Veterans Affairs Healthcare System, Miami, Florida, United States*

High-need high-risk (HNHR) veterans are medically complex and at the highest risk of hospitalization and long-term institutionalization. Technology can mitigate challenges these veterans have in accessing healthcare. Willingness to use technology as well as access and ability to use technology were assessed in this study. At the time of the survey, 2543 Miami VAHS veterans were listed as HNHR. 634 veterans ultimately completed the questionnaire, and 602 answered the “willingness to use video-visits” question. Of the 602 respondents, 327 (54.3%) reported they were willing for video-visits with the VA, while 275 (45.6%) were not. Those who were willing were significantly younger ($P < 0.001$), with higher educational qualifications ($P = 0.002$), and more health literate than those not willing ($P < 0.001$). They were more also capable of using the Internet, more likely to use email and be enrolled in the VA’s patient portal, My HealtheVet ($P < 0.001$). However, of the veterans who were willing, 248 (75.8%) had a device with video-capable technology. Those with video-capable technology were younger ($P = 0.004$), more health literate ($P = 0.01$), and less likely to be Black or African American ($P = 0.007$). They were more capable of using the Internet, more likely to use email, and be enrolled in My HealtheVet than those without ($P < 0.001$). Half of the respondents were willing for video-visits but a quarter of those willing lacked requisite technology, thereby making only about 41.2% of the respondents willing and video-capable. To minimize the digital divide, especially during the ongoing COVID-19 pandemic, targeted measures need to address these disparities in this vulnerable population.

USER PERCEPTIONS & SUBJECTIVE MEMORY CONCERNS ARE ASSOCIATED WITH BRIEF, REMOTE COGNITIVE ASSESSMENT PERFORMANCE

Samuel Lee,¹ Katherine Dorociak,² Nora Mattek,³ Sarah Gothard,³ Jonathan Lee,⁴ Jeffrey Kaye,³ and Adriana Hughes,⁵ 1. *University of Minnesota, Twin Cities, Minneapolis, Minnesota, United States*, 2. *Palo Alto VA Health Care System, Palo Alto, California, United States*, 3. *Oregon Health & Science University, Portland, Oregon, United States*, 4. *Oregon Center for Aging and Technology, Portland, Oregon, United States*, 5. *Minneapolis VA Health Care System, Minneapolis, Minnesota, United States*

Online cognitive tests offer a cost-effective, accessible means of cognitive screening and may prove especially important for individuals with memory complaints, a risk factor for cognitive impairment (Kaup et al., 2015). Although older adults’ perceptions of everyday technologies impact their uptake and adoption, there is limited understanding about how perceptions of online cognitive screening tests impact test performance. The purpose of the current study was to

examine relationships between performance on a brief, self-administered, web-based cognitive assessment tool (SMART) and user perceptions (e.g., ratings of challenge and length), technology confidence, brain health activities, and memory complaints. Participants were 1336 adults without a diagnosis of cognitive impairment (Mage=60.48 years, SD=15.18; 65.8% female; 81.8% White; 21.2% with subjective memory complaints). Most participants (97%) were willing to complete the SMART again, with over half (53.5%) willing to complete the SMART on at least a weekly basis. After adjusting for age and education, better SMART performance (i.e., faster completion time) was associated with user ratings of greater ease of completion, higher technology confidence, and greater participation in brain health activities ($p < .05$). In a subsample aged 60+, individuals with memory complaints took longer to complete certain SMART tasks (Trail Making Test B, Total SMART) than those without memory complaints ($p < .05$). Results suggest that the SMART is a well-accepted tool for frequent remote cognitive screening and highlight the importance of user perceptions, technology confidence, and memory complaints on online cognitive test performance.

USING ARTIFICIAL INTELLIGENCE TO IMPROVE PAIN ASSESSMENT AND PAIN MANAGEMENT: A SCOPING REVIEW

Meina Zhang,¹ Linzee Zhu,¹ Shih-Yin Lin,² Keela Herr,¹ and Nai-Ching Chi,³ 1. *University of Iowa, Iowa City, Iowa, United States*, 2. *New York University, New York, New York, United States*, 3. *University of Iowa, university of Iowa, Iowa, United States*

Approximate 50 million U.S. adults experience chronic pain. It is a widely held view that pain has been linked to sleep disturbance, mental problems, and reduced quality of life. Uncontrolled pain has led to increased healthcare utilization, hospitalization, emergency visits, and financial burden. Recognizing, assessing, understanding, and treating pain can improve outcomes of patients and healthcare use. A comprehensive synthesis of the current use of AI-based interventions in pain management and pain assessment and their outcomes will guide the development of future clinical trials. This review aims to investigate the state of the science of AI-based interventions designed to improve pain management and pain assessment for adult patients. The electronic databases Web of Science, CINAHL, PsycINFO, Cochrane CENTRAL, Scopus, IEEE Xplore, and ACM Digital Library were searched. The search identified 2131 studies, and 18 studies met the inclusion criteria. The Critical Appraisals Skills Programme was used to assess the quality. This review provides evidence that machine learning, deep learning, data mining, and natural language processing were used to improve efficient pain recognition and pain assessment (44%), analyze self-reporting pain data (6%), predict pain (6%), and help physicians and patients to more effectively manage with chronic pain (44%). Findings from this review suggest that using AI-based interventions to improve pain recognition, pain prediction, and pain self-management is effective; however, most studies are pilot study which raises concerns about the generalizability of findings. Future research should focus on examining AI-based approaches on a larger cohort and over a longer period of time.

Session 9055 (Poster)

Alzheimer's Disease and the Brain

AGE-ASSOCIATED EPIGENETIC ALTERATIONS, SOMATIC MUTATIONS, AND THEIR CROSSTALK IN ALZHEIMER'S DISEASE

Yaroslav Markov, Kyra Thrush, and Morgan Levine, *Yale University, New Haven, Connecticut, United States*

Aging is the major risk factor for Alzheimer's Disease (AD), and as life expectancy increases, neurodegeneration will continue to afflict an ever-increasing proportion of the population. While numerous theories are attempting to explain the drivers behind AD pathology, what unites them is the observation that AD is reliably associated with a progressive buildup of age-related molecular changes. Because of the varying clinical presentations of AD in patients with similar genetic backgrounds, it has been postulated that epigenetics may be implicated in its etiology. Building on our prior work showing that AD pathology is linked to alterations in age-related DNA CpG methylation (DNAm) across various brain regions, we use state-of-the-art machine learning approaches to identify patterns of molecular damage in postmortem brain samples. We show that alterations in DNAm are associated with accelerated biological aging, AD, and the APOE e4 genotype, which is a major risk factor for AD. We also demonstrate that these associations are present in the PFC but not cerebellum -- in line with the current understanding of AD progression in the brain. Finally, we perform whole-exome sequencing and protein mass spectrometry on the same brain samples to test our hypothesis as to whether AD-associated alterations of DNAm are linked with the accumulation of somatic mutations that affect the structural and binding properties of protein epigenetic regulators.

ANGIOTENSIN RECEPTOR BLOCKERS UPREGULATE ANGIOTENSIN TYPE 4 RECEPTOR IN BRAINS OF COGNITIVELY INTACT INDIVIDUALS

Caglar Cosarderelioglu,¹ Claudene J. George,² Qian-Li Xue,³ Esther Oh,³ Luigi Ferrucci,⁴ David Bennett,⁵ Jeremy Walston,³ and Peter M. Abadir,³ *1. Ankara University School of Medicine, Cankaya, Ankara, Turkey, 2. Albert Einstein College of Medicine/Montefiore Medical Center, New York City, New York, United States, 3. Johns Hopkins University School of Medicine, Baltimore, Maryland, United States, 4. National Institute on Aging, Baltimore, Maryland, United States, 5. Rush University, Chicago, Illinois, United States*

The primary dementia-protective benefits of Angiotensin receptor type 1 (AT1R) blockers (ARBs) are believed to arise from systemic effects on blood pressure. However, there is a brain-specific renin-angiotensin system (b-RAS) that acts mainly through three receptor subtypes: AT1R, AT2R, and AT4R. AT1R promotes inflammation and oxidative stress (OS). AT2R increases nitric oxide. AT4R is essential for dopamine release and mediates memory consolidation. Here, we aimed to investigate the effects of ARBs on b-RAS, OS, inflammation, PHF-tau, and beta-amyloid load. Postmortem frontal-cortex brains of age- and sex-matched cognitively

intact (CI) individuals using (n=30) and not using ARBs (n=30) and Alzheimer's disease (AD) patients using (n=30) and not using ARBs (n=30) were studied. Protein levels of receptors were measured by Western blot. Protein carbonyl (PC) and cytokine levels were measured by ELISA. Tangle and amyloid- β scores were used as outcomes. In CI individuals, our data shows that ARB treatment was associated with higher protein levels of AT4R (median(range) 0.69(1.92) vs 0.17(1.18) CI+ARBs vs CI, $p=0.02$), lower level of OS marker PC (10.60(8.32) vs 11.26(7.44), CI+ARBs vs CI, $p=0.03$) and lower hippocampal and overall amyloid scores (0(5.45) vs 1.15(4.21) $p=0.03$, 0.79(12.75) vs 3.41(13.36) $p=0.04$, CI+ARBs vs CI, respectively). In AD group, ARB treatment was associated with lower AT1R protein levels (0.47(1.15) vs 0.59(1.99), AD+ARBs vs AD, $p=0.02$). No significant changes were observed in OS, inflammation, or PHF-tau and amyloid load in AD brains treated with ARBs. Our results highlight the impact of ARBs on the brains of cognitively intact and AD older individuals.

COMPARING CORTICAL DEMYELINATION IN GERIATRIC MILD TRAUMATIC BRAIN INJURY AND ALZHEIMER'S DISEASE

Shania Wang,¹ Nahian Chowdhury,¹ Sean Mahoney,¹ and Andrei Irimia,² *1. University of Southern California, Los Angeles, California, United States, 2. University of Southern California, University of Southern California, California, United States*

Mild traumatic brain injury (mTBI) accelerates the rate of age-associated brain atrophy, whose pattern resembles the cortical neurodegeneration pattern observed in Alzheimer's disease (AD). Because the ratio R of T1-to-T2-weighted magnetic resonance imaging (MRI) intensities is a surrogate measure of cortical myelin concentration, mapping and quantifying changes in this ratio can improve our understanding of demyelination after geriatric mTBI and AD. T1- and T2-weighted MRIs were acquired acutely and ~6 months post-injury from 68 healthy controls (HCs, age (years, y): $\mu = 76$ y, $\sigma = 4$ y), 19 mTBIs (age $\mu = 70$ y, $\sigma = 5$ y), and 33 ADs (age $\mu = 77$, $\sigma = 6$). Volumes were co-registered using 3D Slicer's BRAINSFit module, and T2-constrained segmentations of T1 volumes were obtained using FreeSurfer. R and its time changes were computed at each cortical location. When comparing mTBI and AD patients to HCs, significant differences in R were found across ~10% and ~23% of the cortex, respectively ($p < 0.05$). When comparing mTBI to AD, the former exhibited significantly less myelin content in the lateral, medial, and ventral temporal lobes ($p < 0.05$), on the medial aspects of superior parietal lobules and superior frontal gyri ($p < 0.05$), and in orbital gyri ($p < 0.05$), whereas AD subjects had less myelin content on lateral aspect of the parietal lobe ($p < 0.05$). These results highlight demyelination differences in mTBI and AD. Future studies should examine the long-term trajectories to quantify the risk of neurodegenerative disease after mTBI.

DECOUPLING OF GLOBAL BRAIN ACTIVITY AND CEREBROSPINAL FLUID FLOW IS LINKED TO ALZHEIMER'S PATHOLOGY

Feng Han,¹ Jing Chen,² Aaron Belkin-Rosen,² Yameng Gu,² Liying Luo,³ Orfeu Buxton,⁴ and Xiao Liu,² *1. the*

Pennsylvania State University, State College, Pennsylvania, United States, 2. The Pennsylvania State University, State College, Pennsylvania, United States, 3. The Pennsylvania State University, University Park, Pennsylvania, United States, 4. The Pennsylvania State University, The Pennsylvania State University, Pennsylvania, United States

Alzheimer's disease (AD) is the most common cause of dementia in the old adult population. AD pathogenesis has been linked to the aggregation of toxic proteins, e.g., amyloid- β and tau. The glymphatic system may play an important role in clearing out these proteins via cerebrospinal fluid (CSF) flows through perivascular and interstitial spaces. Recent studies have suggested low-frequency (<0.1 Hz), sleep-dependent global blood-oxygenation-dependent-level (gBOLD; global resting-state functional MRI signal) during resting state is coupled with CSF movements, suggesting their potential link to glymphatic function. Here, we directly investigated whether the coupling between the gBOLD and CSF signals is related to AD-related pathology. By analyzing neuroimaging, neurobiological, and neuropsychological data from 118 human subjects (58-90 years of age; AD, early-stage AD, and control subjects included) collected in the Alzheimer's Disease Neuroimaging Initiative project, we found a strong coupling between the gBOLD and CSF signals. More importantly, the strength of this gBOLD-CSF coupling was significantly correlated with cortical amyloid- β level ($p = 0.019$), cognitive decline in the subsequent two years ($p = 0.013$), disease severity ($p = 0.035$), and several AD-related risk factors, including aging ($p = 0.011$), and gender ($p = 0.026$). These findings provide initial evidence for the critical role of resting-state low-frequency (<0.1 Hz) neural/physiological dynamics in AD pathology. They also suggest that the gBOLD-CSF coupling may serve as a non-invasive imaging marker for gauging the glymphatic function.

LOCAL ATROPHY OBSERVED IN SUBJECTIVE COGNITIVE DECLINE VARIES BASED ON QUESTIONNAIRE EMPLOYED IN ADNI

Cassandra Morrison,¹ Mahsa Dadar,² Neda shafiee,² and Louis Collins,³ 1. *McConnell Brain Imaging Centre, Montreal Neurological Institute, McGill University, Montréal, Quebec, Canada, 2. McGill University, Montreal, Quebec, Canada, 3. McConnell Brain Imaging Centre, Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada*

Background: Subjective cognitive decline (SCD) may be associated with increased risk for Alzheimer's disease. However, neither research nor clinical practices have implemented a universal approach to operationalize SCD. This study was designed to determine whether four different methods of defining SCD influence atrophy differences observed between SCD and normal controls (NC). **Methods:** We included MRI scans from 273 participants (NC and SCD) from the Alzheimer's Disease Neuroimaging Initiative. We used four methods to operationalize SCD: Cognitive Change Index (CCI), Everyday Cognition Scale (ECog), Worry, and ECog+Worry. Deformation-based morphometry was performed to examine volumetric change at the lateral ventricles, amygdala, and superior temporal regions (CerebrA atlas; Manera et al., 2020)). A previously validated MRI

analysis method (SNIPE) was used for volume and grading of the hippocampus and entorhinal cortex (Coupe et al., 2012). A logistic regression was completed to examine the association between diagnosis and atrophy in SCD and NC. **Results:** Left hippocampal grading was lower in SCD than NC with the CCI ($p=.041$) and Worry ($p=.021$). When using ECog+Worry, smaller left entorhinal volume was observed in SCD than NC ($p=.025$). Both the right ($p=.008$) and left ($p=.003$) superior temporal regions were smaller in SCD than NC, with only the ECog. **Conclusion:** Although SCD questionnaires are designed to measure the same construct, the results here suggest otherwise. These results suggest that the SCD questionnaire employed will influence whether atrophy is observed in SCD relative to NC. Future research is warranted to better understand how different methodologies result in inconsistent findings.

OBESITY BODY MASS INDEX IN LATE-LIFE AS A PROTECTIVE FACTOR FOR MILD COGNITIVE IMPAIRMENT, DEMENTIA AND DEATH

Ginny Natale,¹ Yun Zhang,² Douglas Hanes,¹ and Sean Clouston,³ 1. *Stony Brook University, Stony Brook, New York, United States, 2. Renaissance School of Medicine, Stony Brook University, Stony Brook, New York, United States, 3. Renaissance School of Medicine, Stony Brook University, Renaissance School of Medicine, Stony Brook University, New York, United States*

Objective The goal of the current study was to estimate the hazards of conversion from unimpaired to mild cognitive impairment (MCI) to probable dementia and death for underweight, normal, overweight and obese older adults in an aging cohort where the timing of examinations may be associated with the severity of dementia. **Methods** We analyzed six waves of the National Health and Aging Trends Study (NHATS); a longitudinal aging cohort. Participants were classified into mutually exclusive cognitive statuses: cognitively unimpaired, MCI, probable dementia and death. Time-to-event ratios and cognitive transitions were examined with multistate survival models accounting for misclassification. BMI was computed from height and weight measurements and expressed in kg/m² and categorized into underweight, normal, overweight and obese. **Results** Participants ($n=6,078$) were 77 years old, on average, and the majority were white, females and high school graduates. About one third (32.68%) of the sample has normal BMI, one third is overweight (35.59%), the rests are obese (26.41%) or underweight (5.33%). After adjusting for the effects of diabetes, CVD, vigorous physical activity, age and race/ethnicity, the protective effect of obesity in late-life against developing dementia ($HR=0.44$; 95%CI[0.29-0.67]) and dying from dementia ($HR=0.63$; 95%CI[0.42-0.95]). **Discussion** Prior research shows the risk of dementia associated with obesity at older ages is either attenuated or reversed. Our findings support a protective factor of obesity in late-life against conversion to dementia and death.

PDE4D AND HCN1 ULTRASTRUCTURE IN RHESUS MACAQUE ENTORHINAL CORTEX: RELEVANCE FOR AGING AND ALZHEIMER'S DISEASE

Dibyadeep Datta,¹ SueAnn Mentone,² and Amy Arnsten,³ 1. *Yale School of Medicine, New Haven, Connecticut, United States, 2. Yale University, New Haven, Connecticut,*

United States, 3. Yale University, Yale University, Connecticut, United States

Tau pathology emerges in a distinct spatial and temporal pattern in Alzheimer's Disease (AD). Anatomical studies in AD subjects and rhesus macaques show earliest signs of tau pathology in the stellate cell islands in entorhinal cortex (ERC) layer II. However, the molecular mechanisms that confer vulnerability to ERC layer II cells early in AD is unknown. cAMP-PKA magnification of calcium release has been seen in prefrontal cortex, associated with HCN channel opening to dynamically regulate synaptic strength. This process is regulated by phosphodiesterases (PDE), regulation that is lost with age. The current study examined whether this "signature of flexibility" could also be seen in layer II ERC, underlying vulnerability to tau pathology with aging. We used high-spatial resolution immunoEM to localize PDE4D and HCN1 in young rhesus macaque (7-10y) ERC layer II. Our results suggest that PDE4D was concentrated on the SER-spine apparatus and in postsynaptic density, and HCN1 expressed in the membrane near excitatory synapses in dendritic spines. Within dendritic shafts, PDE4D labeling was observed along microtubules and near mitochondria, whereas HCN1 was organized in discrete clusters along the plasma membrane. These data suggest that PDE4D is optimally positioned to modulate cAMP microdomains and control calcium extrusion from the SER. HCN1 channels are localized in subcompartments to facilitate dynamic physiological representation of sensory experience and visual space governed by cAMP-PKA signaling. The anatomical patterns in ERC layer II corroborate our findings in vulnerable glutamatergic circuits in prefrontal cortex, suggesting conserved molecular features in association cortices most susceptible in AD.

PHENOTHIAZINES TO TREAT ALZHEIMER'S DISEASE

Rachel Litke,¹ Bik Tzu Huang,² Damian Gonzalez,² Martine Rampanana,² Nicholas Grimaldi,² and Charles Mobbs,³ 1. *icahn school of medicine at mount sinai, New York, New York, United States*, 2. *Icahn School of Medicine at Mount Sinai, New York, New York, United States*, 3. *Icahn School of Medicine at Mount Sinai, new york, New York, United States*

Current treatments of Alzheimer's Disease (AD) are largely ineffective and do not address underlying pathophysiological processes. The model organism *C. elegans* has been successfully used to discover compounds to treat human diseases, some now in clinical trials. To develop novel drugs and explore pathways to treat AD, we took on a forward pharmacological approach with a *C. elegans* model for AD, completed with studies to expand results to lifespan as well as healthspan. We screened 2560 drugs from the Microsource Spectrum library for their ability to delay proteotoxicity (indicated by paralysis) in an Abeta transgenic *C. elegans* muscle model of AD (CL2006) in liquid medium. Among the most protective drugs were phenothiazines, which are orally active and cross the blood-brain barrier, desirable properties of drugs to treat AD. 80 phenothiazines congeners were further assessed; 60% were protective in CL2006 worms. 9/20 tested phenothiazines increased lifespan in N2 worms and 2/3 phenothiazines tested promoted significantly higher pharyngeal pumping rates compared with control till day 10 of

adulthood in N2 worms. 2 of the drugs were protective in the *C. elegans* neuronal model of AD. This phenotypic screening approach led to the discovery of potential drugs to treat AD. These phenothiazines protect against Abeta toxicity, and assessment of efficacy to protect against other forms of proteotoxicity are ongoing. These studies suggest the utility of *C. elegans* to discover drugs to treat human diseases. Future studies will assess molecular mechanisms mediating the protective effects of these compounds.

QUANTIFICATION OF SIMILAR NEURODEGENERATION ACROSS GERIATRIC CONCUSSIONS AND ALZHEIMER'S DISEASE

Andrei Irimia, and Kenneth Rostowsky, *University of Southern California, University of Southern California, California, United States*

Geriatric mild traumatic brain injury (mTBI) is a risk factor for Alzheimer's disease (AD), but few studies have studied how the neuroanatomic effects of these conditions can converge onto similar brain structure trajectories. Here we use magnetic resonance imaging to investigate similarities between mTBI and AD across both white and gray matter (WM and GM, respectively) using measures like fractional anisotropy (FA, a surrogate measure of WM integrity) and cortical thickness. We identify statistically significant similarities in neurodegeneration across mTBI (N = 33; age μ = 63 years (y), σ = 11 y) and AD (N = 66; age μ = 76 y, σ = 9 y) by testing for statistical equivalences of mean FA and cortical thickness. Both WM and GM are found to exhibit significant similarities in how mean FA and cortical thickness decrease, respectively, across mTBI and AD. For WM, the broadest spatial extent of statistical similarity between conditions, quantified as percentages of structures' volumes, is found within the superior fronto-occipital fasciculus (left (L): 91%, $p < 0.05$; right (R): 95%, $p < 0.05$), and in the crura of the fornix (L: 65%, $p < 0.05$; R: 80%, $p < 0.05$). Across mTBI and AD, cortical thinning trajectories are most similar in the superior precentral sulcus (L: 91%, $p < 0.05$; R: 100%, $p < 0.05$), and anterior lateral sulcus (L: 75%, $p < 0.05$; R: 86%, $p < 0.05$). Future studies should leverage such findings to identify AD risk factors in mTBI patients.

REMYELINATION IMPROVES VOIDING DYSFUNCTION IN A MOUSE MODEL OF MULTIPLE SCLEROSIS

Ramalakshmi Ramasamy, Cara Hardy, Stephen Crocker, and Phillip Smith, *UConn Health, Farmington, Connecticut, United States*

Multiple sclerosis (MS) is a chronic inflammatory demyelinating disease of the central nervous system (CNS). Of note, over 80% of MS patients have urinary symptoms as one of their earliest symptoms. Since MS patients often live into older age, urinary incontinence and retention are significant problems affecting their quality of life. Although several studies show that inflammatory-demyelinating animal models of MS develop bladder dysfunction, the confounding influence of systemic inflammation in these models limits potential interpretation on the contribution of CNS-myelination to bladder dysfunction. We sought to address this knowledge gap using the cuprizone model of demyelination and remyelination. C57Bl/6 mice were treated with dietary

cuprizone (0.2%w/w) for four weeks to induce demyelination. One group was allowed four additional weeks for recovery and remyelination. We performed voiding spot assay (VSA), urethane-anesthetized cystometry, and CNS-histology to assess demyelination-induced differences in urinary performance. We observed that cortical demyelination causes significant aberrance in voiding behavior (conscious cortical control) characterized by increased micturition frequency and reduced volume per micturition. Interestingly, remyelination restored healthy bladder function. However, there were no significant changes in the cystometric parameters (brainstem reflex) between the treatment groups. While MS is not classically considered a disease of aging, extending the longevity of these patients has not been reciprocated with improved treatments for their most-bothersome conditions, notably urinary symptoms that persist throughout life. Our data represent a novel compelling connection and strong correlation between CNS-myelination and cortical control of bladder function, which has potential implications in MS, aging, and aging-associated neurological disorders.

SENOLYTICS IN A MODEL OF ALZHEIMER'S DISEASE

Ellen Wang, and Suckwon Lee, *Buck Institute for Research on Aging, Novato, California, United States*

The therapeutic effects of senescent cell killing with senolytics in neurodegeneration mouse models poise this strategy as an intervention candidate for Alzheimer's Disease (AD). However, it is unclear whether senolytic therapies for AD are translatable to human cells. To determine whether senolytics could be a viable therapeutic for AD, we have treated long-term mixed human neuron/astrocyte primary cultures with amyloid beta oligomers (ABO), which we have shown to induce a phenotype consistent with senescence in neurons. Fifteen days after ABO treatment, we administered Navitoclax (Nav) and the natural killer cell-line NK92, which are known to selectively kill senescent cells in the periphery. Following treatment, we assessed senescence markers in our cultures as well as senescent cell killing selectivity through cleaved Caspase 3 quantification. Our preliminary data show that Nav (8, 4, and 0.5uM) kills both control and ABO treated cells. NK92 cells (10 to 1 effector to target ratio) also kill some control cells, suggesting there is not a clear cut mechanism by which NK92 cells can distinguish senescent from non-senescent neurons or astrocytes. Although analysis of selective killing is ongoing, off-target killing indicates that we need more refined senolytic strategies to implement their safe human use.

SHORT-TERM DIESEL EXHAUST EXPOSURE RESULTS IN NEUROINFLAMMATION AND WHITE MATTER INJURY

Krista Lamorie-Foote,¹ Kristina Shkirkova,² Qinghai Liu,² Constantinos Sioutas,² Todd Morgan,² Caleb Finch,² and William Mack,³ 1. *University of Southern California - Keck School of, Los Angeles, California, United States*, 2. *University of Southern California, Los Angeles, California, United States*, 3. *Keck School of Medicine of the University of Southern California, Los Angeles, California, United States*

Ambient air pollution (AAP) exposure is associated with white matter injury and cognitive decline in older adults (Chen et al. 2020, Erickson et al. 2020). Neuroinflammation and

oxidative stress may contribute to this white matter injury. Diesel exhaust particulate matter (DEP) is a neurotoxic component of AAP. This study characterizes the time course by which neuroinflammation/oxidative stress occurs and results in white matter injury following DE exposure in a murine model. DEP (Sigma) was re-aerosolized for exposure. Mice were exposed to 100 µg/m³ DEP or filtered air (FA) for 5 hours (n=8/group), 100 hours (n=6/group), or 200 hours (n=6/group). Immunohistochemical analysis of degraded myelin basic protein (dMBP), a marker of myelin damage, was performed. Neuroinflammation and oxidative stress were assessed by histological analysis of complement C5a, an anaphylatoxin, and 4-Hydroxynonenal (4-HNE), a marker of lipid peroxidation. dMBP integrated density was increased in the corpus callosum of DEP mice at 5 (p<0.01), 100 (p<0.01), and 200 hours (p<0.001) compared to FA mice. C5a integrated density was increased in the corpus callosum of DEP mice at 5 (p<0.01), 100 (p<0.01), and 200 hours (p<0.01) compared to FA mice. 4-HNE integrated density was increased in the corpus callosum of DEP mice at 5 (p<0.001), 100 (p=0.001), and 200 hours (p<0.001) compared to FA mice. Neuroinflammation and oxidative stress are upregulated with associated white matter injury in the corpus callosum after 5 hours of DEP exposure. Short-term DEP exposure activates inflammatory/oxidative stress pathways, which may contribute to the pathogenesis of white matter injury. Erickson et al. 2020, PMID:32182984; Chen et al. 2020, PMID:32669395.

SIGNIFICANT ASSOCIATIONS OF THE INTERPLAY BETWEEN STRESS RELATED GENES WITH ALZHEIMER'S DISEASE

Anatoliy Yashin,¹ Deqing Wu,¹ Konstantin Arbeev,¹ Olivia Bagley,¹ Igor Akushevich,¹ Matt Duan,¹ Arseniy Yashkin,² and Svetlana Ukraintseva,¹ 1. *Duke University, Durham, North Carolina, United States*, 2. *Duke University, Morrisville, North Carolina, United States*

The lack of efficient medication against Alzheimer's disease (AD) is the most important problem for this health disorder today. One possible reason for this -- the implementing medical interventions "too late in the disease stage" -- has been recently addressed in the initiative that defined the preclinical AD stage by measuring changes in preclinical AD biomarkers. According to this definition, beta amyloid (Aβ) is one of the key preclinical AD biomarkers. Experimental studies showed that Aβ results from proteolytic cleavage of APP by β- and γ-secretases. Production of β-secretase involves BACE1 gene, activated by cellular stress response. This suggests that AD might be initiated by cellular stressors and that multifactorial regulation of AD is likely to be driven by genes involved in cellular stress response. In this paper we investigate whether interplay between SNPs from the EIF2AK4 gene involved in sensing cellular stress signals and the APP gene dealing with Aβ production may be associated with AD in human data. For this, we evaluated association of the interactions of the pairs of SNPs from these genes with AD in the analysis of HRS data. We found that interactions between several SNPs have statistically significant associations with AD. The results of this analysis confirm that the interplay between gene served as a sensor of cellular stress and gene involved in production of preclinical AD biomarker in response to

stress may influence human AD. This analysis illustrates an important step towards translation of the results of experimental AD studies to human applications.

SYSTEMIC BIOENERGETIC CAPACITY CHANGES WITH COGNITIVE STATUS AND INSULIN SENSITIVITY IN OLDER ADULTS

Gargi Mahapatra,¹ Zhengrong Gao,¹ James Bateman,² Jenny L. Gonzalez-Armenta,² Allison Amick,³ Ramon Casanova,² Suzanne Craft,⁴ and Anthony J. A. Molina,⁵ 1. *Sticht Center for Healthy Aging and Alzheimer's Prevention, Winston-Salem, North Carolina, United States*, 2. *Wake Forest School of Medicine, Winston-Salem, North Carolina, United States*, 3. *Wake Forest School of Medicine, Wake Forest School of Medicine, North Carolina, United States*, 4. *Wake Forest School of Medicine, Winston Salem, North Carolina, United States*, 5. *University of California, San Diego, La Jolla, California, United States*

Systemic mitochondrial dysfunction is reported with AD progression, suggesting that peripheral blood cells may be used to investigate systemic mitochondrial alterations related to cognitive decline. We aimed to identify bioenergetic signatures associated with AD-related dementia and differences in insulin sensitivity associated with AD risk. We analyzed mitochondrial bioenergetics in peripheral blood cells collected from 365 older adults with varying cognitive status (normal, mild cognitive impairment, and AD) and insulin sensitivity. Normoglycemic individuals exhibited lower maximal bioenergetic capacity with AD (PBMCs: 239.6 pmol·min⁻¹, $p = 0.02$; Platelets: 151.7 pmol·min⁻¹, $p = 0.06$) compared to normal cognition (PBMCs: 271.5 pmol·min⁻¹; Platelets: 171.7 pmol·min⁻¹). Individuals with impaired insulin sensitivity exhibited lower maximal bioenergetic capacity in platelets with AD (171.6 pmol·min⁻¹, $p = 0.008$) compared to normal cognition (210.6 pmol·min⁻¹). Participants with impaired insulin sensitivity also exhibited unique bioenergetic profiles exemplified by overall higher levels of mitochondrial respiration, indicating that comorbidities such as diabetes can significantly influence bioenergetic capacity. We observed strong positive associations between maximal respiration in normoglycemic individuals with cognitive function, as measured by Modified Preclinical Alzheimer's Cognitive Composite (mPACC5) ($p = 0.06$), and fatty acid oxidation in individuals with impaired insulin sensitivity with cortical thickness ($p = 0.05$). This study demonstrates that circulating cells may provide a cost-effective and minimally invasive way to monitor systemic bioenergetic changes associated with AD risk, progression, and insulin sensitivity. These findings also suggest that blood-based bioenergetics are related to key features of AD development and progression and should be further developed as a potential biomarker.

THE HUMAN GENES THAT LINK MIDDLE-AGE COMORBIDITIES AND ALZHEIMER'S DISEASE

Shin Murakami, *Touro University California, Vallejo, California, United States*

Advancements in biomedical research have identified the genes influencing life spans, stress resistance and age-related diseases, including Alzheimer's disease. Stress resistance includes resistance to multiple forms of stress, pathogens and toxic beta-amyloid which is tightly associated with Alzheimer's disease. We have investigated 431 human genes that are associated with co-morbidities (Vahdati Nia et al, 2017; Le et al.,

2020). Those genes are involved in lipid metabolism, hemostasis, homeostasis, neuroendocrine and immune functions. The genes are relevant to middle-life health. We explore a wide variety of co-morbidities that could happen in middle to late life. I will give a brief review of increased stress resistance, and genetic markers associated with co-morbidities. I will discuss how the studies may benefit to fight against COVID-19. References: 1. Vahdati Nia B, Kang C, Tran MG, Lee D, Murakami, S. (2017) *Front. Genet.* 8:55. doi: 10.3389/fgene.2017.00055 2. USING DROSOPHILA TO IDENTIFY NATURALLY-OCCURRING MODIFIERS OF ALZHEIMER'S DISEASE

Adrienne Wang,¹ Ming Yang,² Cecilia Fitzgerald-Cook,² Ben Harrison,² Akimi Green,¹ Kensington Hartman,¹ Matthew Zinkgraf,¹ and Daniel Promislow,² 1. *Western Washington University, Bellingham, Washington, United States*, 2. *University of Washington, Seattle, Washington, United States*

Despite significant progress in identifying risk factors for late-onset Alzheimer's Disease (LOAD), much of the variance in disease pathogenesis remains unexplained, likely due to the contribution of many genes of small effect size. Model organisms such as *Drosophila Melanogaster* exhibit conservation in both disease-causing genes and cellular processes implicated in Alzheimer's Disease (AD), offering a genetically tractable model that can be statistically leveraged to identify causal variants. Here, we combine a *Drosophila* model of AD with the *Drosophila* Genetic Reference Panel (DGRP), a model of natural variation consisting of over 200 fully sequenced, isogenic lines derived from a wild-caught population. Expression of two proteins closely associated with AD pathogenesis, A β 42 and Tau, in the *Drosophila* eye results in a "rough eye" phenotype, an easily quantifiable phenotype caused by degeneration of the ommatidial array. By quantifying the degree of A β 42- and Tau-mediated degeneration across 164 lines of the DGRP and using a gene-based approach to map associations, we have identified and validated a subset of naturally occurring modifiers of degeneration in *Drosophila*. Enrichment analysis reveals that the set of genes identified in our screen show significant enrichment for genes identified as significant or suggestive ($4 \times 10^{-6} > p > 2 \times 10^{-11}$) in human GWAS studies. The results presented here provide proof-of-principal for an approach that combines the strengths of forward genetic screens in model organisms with the power of human GWAS studies to identify and validate potential risk factors that have been difficult to detect in human studies alone.

Alzheimer's Disease and Other Dementias II

COLLECTION OF DATA ON PERSONS LIVING WITH DEMENTIA WHO GO MISSING: FIRST RESPONDER PERSPECTIVES

Noelannah Neubauer,¹ Serrina Philip,¹ Samantha Dawn Marshall,² Christine Daum,³ Hector Perez,¹ Antonio Miguel-Cruz,⁴ and Lili Liu,¹

1. *University of Waterloo, Waterloo, Ontario, Canada*,
 2. *University of Waterloo, University of Waterloo, Ontario, Canada*,
 3. *University of Waterloo, Edmonton, Alberta, Canada*,
 4. *University of Alberta, Edmonton, Alberta, Canada*

While it is commonly cited that 60% of persons living with dementia (PLWD) wander, it is unclear whether this number reflects global contexts. Population aging has created a pressing need for the development of programs to mitigate the risks of PLWD from getting lost and going missing. Such programs would require a national strategy for the collection and integration of data on missing incidents involving this population. This study is a first step to inform such a strategy. The purposes were to: 1) identify approaches to data collection on missing persons incidents involving PLWD among Canadian police and search and rescue (SAR) organizations; 2) describe the foreseeable challenges associated with developing a national data collection strategy. We used generic qualitative description to generate data with fifteen key informants. Virtual semi-structured interviews were completed and transcribed verbatim. Content analysis and trustworthiness strategies guided analysis and rigor. Our findings indicate that police and SAR organizations collect a multitude of data pertaining to missing incidents involving PLWD. However, there is a lack of standardization in data collection, entry and analysis. Privacy legislation, limited resources, and incompatible data management systems pose challenges to data sharing and interoperability. Underreporting of missing incidents to police results in an underestimation of missing incidents. An intersectoral, uniform approach to data collection would enable the storage, analysis and comparison of national data. Accurate data on critical wandering can inform prevention, search strategies, resource allocation and effectiveness of programs.

DEMENTIA CARE MANAGEMENT: SOCIAL CAPITAL FOR PERSONS WITH DEMENTIA THAT LIVE ALONE

Adria Navarro,¹ Vickie Avila,¹ and Lynne Conger

² 1. *Azusa Pacific University, Azusa, California, United States*, 2. *Alzheimer's Orange County, Irvine, California, United States*

Social connections are critical for healthy aging (Ahn et al., 2020). Consistent findings in research for persons with dementia that live alone show that a natural support network is the gold-standard for success, as social capital enhances well-being. Therefore a community-based intervention was piloted as part of a national 'special populations grant' in partnership with the local Meals-on-Wheels program. Dementia care management provided by graduate social work interns sought to provide weekly supportive contacts. Quantitative data was collected at baseline and following the program through administration of standardized measurement tools for "thriving" and for "dementia quality

of life." The sample to date (N=33) consists of a majority being white females (82.4%), with additional participants expected as the remaining enrolled complete the program. These early "completers" do not show significant changes in their specific "surviving to thriving" domains, yet they do report greater perceptions of quality in their life as a whole following the dementia care management intervention when comparing post data to their baseline (Chi Square 18.95, $p=0.004$). To date this intervention continues to be studied and suggests a positive impact is likely for older adults with dementia that live alone, as well as for the communities where they reside.

DEVELOPING INFORMATION TECHNOLOGIES TO PROMOTE DEMENTIA E-FRIENDLY COMMUNITIES FOR COVID-19 AND BEYOND

Nicole Ruggiano,¹ Yan Luo,² Amy Hurd,³ Kristen Lawlor,³ Monica Anderson,³ Zhe Jiang,³ and Jeff Gray,³ 1. *University of Alabama, Hoover, Alabama, United States*, 2. *The University of Alabama, Tuscaloosa, Alabama, United States*, 3. *University of Alabama, Tuscaloosa, Alabama, United States*

People living with dementia (PLWD) and their caregivers often face barriers to education, support, and services that can improve their health and quality of life. Information technology (IT) has been suggested as a solution to overcoming such barriers, though the development of evidence-based IT for dementia care is still developing. This project gathered stakeholder (e.g., providers, caregivers) perspectives on the development of a proposed IT solution to support community asset mapping that would allow families to self-assess their dementia-related service needs, educate them about available services, and link them with services they need in their community. This proposed IT would create a dementia resource database that relies on crowdsourced data from community stakeholders as well as relevant data mined from existing sources (e.g., CMS certified nursing home data). As part of the planning process, this project conducted qualitative interviews with providers and caregivers in four metro areas in Alabama and their surrounding rural communities to learn more about the content and features that stakeholders perceive as being most effective for the proposed technology. Stakeholders also discussed their experience of utilizing IT solutions during the COVID-19 pandemic to promote access and continuum of care when barriers to service intensified. Thematic findings provide detail on: 1) motivating factors among stakeholders to contribute crowdsourced data that support community members affected by dementia; 2) potential barriers to implementing IT for dementia support, based on experiences with IT use during COVID-19; and 3) how stakeholders envision IT to better connect community members with needed services.

EFFECT OF DANCE MOVEMENT THERAPY ON DEPRESSION AND ANXIETY FOR PERSONS WITH DEMENTIA: A SYSTEMATIC REVIEW

Ying Wang,¹ Mandong Liu,² Zhixiao Dong,³ Jing wu,⁴ Huan Cui,³ Dianjun Shen,⁴ and Youyou Tan,³ 1. *Lanzhou University, Lanzhou, Gansu, China (People's Republic)*, 2. *University of Southern California, Hangzhou, China (People's Republic)*, 3. *Lanzhou University, Lanzhou, Gansu, China (People's Republic)*, 4. *Lanzhou University, Lanzhou Nniversity, Gansu, China (People's Republic)*

Dance movement therapy (DMT) is a physical and psychological intervention, but there was no meta-analysis of RCTs in the systematic review of DMT for dementia, and the results of RCTs were inconsistent. The study aimed to assess the effectiveness of dance movement therapy on depression and anxiety of persons with dementia in comparison to no treatment, standard care. Six electronic databases (Cochrane, PsycINFO, Web of Science, PubMed, EBSCO, CNKI) were searched through January 2021. Randomized controlled trials (RCTs) in Chinese and English language were considered, including: (1) population is women and men of all age with dementia and MCI; (2) intervention is dance movement intervention; (3) comparison is no treatment or standard care; (4) outcome is depression or anxiety. The four review authors independently reviewed studies on an abstract/title level and again after reading the full paper, and we independently evaluated methodological quality. Six randomized controlled trials were identified on depression and anxiety symptoms in persons with dementia. The target sample size was 29-842 older adults. Meta-analysis showed there were significant differences in favor of dance in depression (SMD = 1.17, 95% CI: 0.39 to 1.95, P = 0.003), but not in outcomes of anxiety. Trials of high methodological quality, large sample sizes, and clarity in the way the intervention is put together and delivered are needed to assess whether dance movement therapy is an effective intervention on depression and anxiety for persons with dementia.

INVOLVING PERSONS WITH DEMENTIA IN SOCIAL RESEARCH: A LITERATURE REVIEW

Pamela Manley,¹ and Candace Kemp,² 1. *Georgia State University/Gerontology Institute, Atlanta, Georgia, United States*, 2. *Gerontology Institute, Georgia State University, Atlanta, Georgia, United States*

Abstract Studies involving persons with dementia as research participants have increased over the years, due in part to an emphasis on patient and public involvement in health care and participatory action research. Recent studies indicate a growing trend toward engaging persons with dementia, not only as participants, but also as co-researchers. Further, studies involving persons with dementia as co-researchers and advisers have garnered increased attention due to the inclusion of this population's unique perspectives and lived experiences. Theoretically, frameworks such as person-centered- and relationship-centered care, also influence and shape the research process. This literature review examines empirical research conducted over the past decade that reports the involvement of persons with dementia as research participants ("research on") and co-researchers and

advisers ("research with"). Among the 27 articles identified, 12 reported "research on," and 15 reported "research with" persons with dementia. "Research on" targeted participants' emotional expressions/responses, engagement in exercise/activities; social environment influences, and cognitive training; whereas "research with," which was mostly qualitative, focused on co-researchers' perspectives of and experiences with the research process; needs, priorities, and recommendations in research planning; partnering with persons with dementia on the design and development of research instruments, and the importance of critically evaluating the research process. Findings documenting research challenges, complexities, and ethical concerns are also discussed. Overall, findings demonstrate the feasibility of involving persons with dementia in a meaningful way and further affirms that including them as co-researchers is not only beneficial, but has the potential to enhance the entire research process.

ONLINE HEALTH INFORMATION WANTS OF CAREGIVERS FOR PERSONS WITH DEMENTIA IN SOCIAL MEDIA

Alison Tang,¹ Jung Kwak,¹ Bo Xie,¹ Lu Xiao,² Sucheta Lahiri,³ Olivia Flynn,³ and Avinav Murugadass,⁴ 1. *The University of Texas at Austin, Austin, Texas, United States*, 2. *Syracuse University, Syracuse University, New York, United States*, 3. *Syracuse University, Syracuse, New York, United States*, 4. *Syracuse University, Syracuse, New York, United States*

Family caregivers of persons with dementia (PWDs) use social media to obtain and share health information. Yet relatively little is known about the types of information that these caregivers share. We address this gap by analyzing caregivers' posts (N = 401) in two subreddits, r/Alzheimers and r/dementia, which represent two subgroups on the social media platform Reddit. Our research questions were as follows: (1) What are these caregivers' main purposes in posting? (2) What types of health information do the caregivers exchange online? (3) What are the characteristics of online posts that receive the caregivers' greatest attention? Content and correlational analyses revealed that over half of users (57%) posted regarding specific types of health information that they desired to seek and share, whereas the remaining users posted information for sharing only. The health information most commonly posted fell into the following three categories: psychosocial health information, information about patients' daily care, and characteristics of health conditions. The more health information types that a post contained, the greater the number of people who participated in the subreddit discussions. Further research should examine how social media meet PWD caregivers' needs for information support.

RISK FACTORS OF GOING MISSING IN PEOPLE LIVING WITH DEMENTIA: A SCOPING REVIEW

Noelannah Neubauer,¹ Hector Perez,¹ Antonio Miguel-Cruz,² Christine Daum,³ Samantha Dawn Marshall,⁴ Elyse Letts,¹ and Lili Liu,¹ 1. *University of Waterloo, Waterloo, Ontario, Canada*, 2. *University of Alberta, Edmonton, Alberta, Canada*, 3. *University of Waterloo, Edmonton, Alberta, Canada*, 4. *University of Waterloo, University of Waterloo, Ontario, Canada*

Critical wandering is common in persons living with dementia, it is defined as wandering that results in an individual going missing. This exposes the missing vulnerable older adult to risks and dangers. Persons with dementia who become lost and go missing and get lost can face adverse outcomes, such as injury and death, yet the amount of information available on the risk factors associated with these incidents is scarce. The aim of this study was to identify the risk factors associated with critical wandering in persons living with dementia. We used Tricco et al.'s (2018) approach for scoping reviews and searched the following databases: Medline, EMBASE, CINAHL, and Scopus. We included studies that referred to critical wandering in persons with dementia, cognitive impairment, or Alzheimer, and published since 1980. We identified 3,376 publications, which was reduced to 1641 publications after we removed duplications. A total of 78 studies met the inclusion and exclusion criteria for analysis and extraction. A rigorous process to synthesize and categorize the research evidence was followed. We identified four different types of risk factors associated with going missing: (1) personal, (2) physical environment and geographical location, (3) cultural environment, and (4) social environment and support resources. Recognition of these risk factors can help persons living with dementia and their care partners identify interventions and proactive strategies to mitigate or prevent critical wandering. This will support persons with dementia, their care partners, and community organizations to balance safety, autonomy, and independence to maximize quality of life.

STRATEGIES FOR IMPLEMENTING MUSIC-BASED INTERVENTIONS FOR PEOPLE WITH DEMENTIA: A SYSTEMATIC REVIEW

Takashi Amano,¹ Joe Strong,² Cole Hooley,³ and Megumi Inoue,⁴ 1. *Rutgers University-Newark, Newark, New Jersey, United States*, 2. *University of Tennessee - Knoxville, Knoxville, Tennessee, United States*, 3. *Brigham Young University, Provo, Utah, United States*, 4. *George Mason University, Fairfax, Virginia, United States*

Previous research has found that music-based interventions are effective at improving several outcomes related to dementia for nursing home residents. Some studies have investigated the implementation of music-based interventions. However, to date, there is no synthesis available regarding strategies and outcomes of these implementation studies. This study aims to synthesize available evidence regarding implementation strategies and outcomes of music-based interventions for nursing home residents with dementia. We conducted a systematic literature search in PsychInfo, PubMed, MEDLINE, CINAHL, and The Cochrane Library. A total of 8 studies were included for the qualitative synthesis. Of the eight studies, half were studies of music therapy and the other half were on individualized music. We identified 49 implementation strategies. The most frequently reported category of strategies was planning (34.7%), followed by education (24.5%), quality management (24.5%), restructuring (12.2%), and finance (4.1%). No strategies under the category of attending to the policy context were reported. We identified 21 implementation outcomes. The most frequently reported category was adoption (33.3%), followed by fidelity (28.6%), appropriateness (19.0%), sustainability (9.5%), acceptability (4.8%), and cost (4.8%). No

studies measured feasibility or penetration. Although various implementation strategies have been utilized, most of them are under the categories related to intervention methods. Less attention has been paid to strategies that aim at structural changes of intervention delivery systems. Future studies should investigate facilitators and barriers of implementing music-based interventions especially focusing on organizational and structural aspects.

UNDERDIAGNOSIS OF DEMENTIA AMONG INDIGENOUS OLDER ADULTS WITH COGNITIVE IMPAIRMENT

Takashi Amano,¹ Carlos Andres Gallegos,² William Waters,³ and Wilma Freire,⁴ 1. *Rutgers University-Newark, Newark, New Jersey, United States*, 2. *University of Vermont, Burlington, Vermont, United States*, 3. *Universidad San Francisco de Quito, Quito, Pichincha, Ecuador*, 4. *Universidad San Francisco de Quito, Universidad San Francisco de Quito, Pichincha, Ecuador*

Early and timely diagnosis of dementia has been recognized as key to improving health outcomes. However, underdiagnosis among the indigenous population has not been adequately investigated. This study examines the association between indigenous ethnic identity and receiving a diagnosis of dementia and identifies factors associated with receiving a diagnosis of dementia. Data were drawn from Ecuador's Survey of Health, Welfare and Aging (SABE) – 2009, based on a probability sample of households in Ecuador with at least one person 60 years or older. This is a robust data set that allows for understanding ethnic dimensions and disparities, especially because of the successful recruitment of indigenous households. The final sample consisted of 1,437 people who had cognitive impairment. Whether participants had ever been told that he/she had dementia was compared between the groups of people who identified themselves either as indigenous or others. Binary logistic regression analysis was utilized. Indigenous participants had a lower probability than others of receiving a diagnosis of dementia after controlling for health and function related covariates. This association became statistically insignificant after including socioeconomic factors in the model. The final model revealed that people who had higher educational attainment were more likely to receive a diagnosis of dementia. Findings suggest that underdiagnosis among indigenous older adults can be explained by their lower socioeconomic status rather than by health and functional status. This finding implies the possibility of developing strategies to promote timely diagnosis by targeting populations who are especially susceptible to underdiagnosis of dementia.

Session 9065 (Poster)

Alzheimer's Disease I (HS Poster)

ALZHEIMER'S DISEASE RISK REDUCTION: AN EVIDENCE-BASED, MULTI-COMPONENT LIFESTYLE PROGRAM, PRE- & INTRA-COVID-19

Gina Touch, and Paul Bendheim, *University of Arizona College of Medicine Phoenix, Phoenix, Arizona, United States*

Alzheimer's disease (AD) is the 5th leading cause of death in the USA. With nearly 300 failed therapeutic trials to date,

lifestyle modifications have been shown to reduce AD risk by as much as 50%. Preceding the FINGER Study by nearly a decade, the BrainSavers Brain+Body Total Fitness program was developed by an interdisciplinary team to reduce the risk of AD / all-cause dementia and promote healthy aging via education, exercise, and engagement. This evidence-based program utilizes the principles of neuroplasticity and cognitive reserve. Pre-Covid, BrainSavers was delivered live, led by certified instructors. Two years of curriculum were developed, comprised of six lifestyle components: cognitive exercise, physical exercise, healthful nutrition, socialization, stress reduction, and sleep hygiene. Results of a six month beta trial documented self-rated improvements in memory and general cognitive performance, quality of life, socialization, nutritional status, and physical fitness. Quantitative results showed statistically significant differences in physical fitness measures including cardio-respiratory endurance, lower body strength, balance, speed, and agility. Trends were seen in six of nine cognitive skills. During Covid the program was transformed into an online format as BrainSavers Synapse: Staying Connected, which has been enthusiastically received. Future research will compare longer-term outcomes of both formats. Based on results to date and extensive peer-reviewed literature on lifestyle as a modifier of dementia risk, we predict this program will contribute to better individual and societal outcomes, including substantial improvements in cognitive and overall health, and a significant reduction in healthcare costs.

ANALYSIS OF SURVIVAL DATA WITH COMPETING RISKS IN ADRD (ALZHEIMER'S DISEASE AND RELATED DEMENTIAS) RESEARCH

Dianxu Ren, Oscar Lopez, and Jennifer Lingler, *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Competing risk is an event that precludes the occurrence of the primary event of interest. For example, when studying risk factors associated with dementia, death before the onset of dementia serve as a competing event. A subject who dies is no longer at risk of dementia. This issue play more important role in ADRD research given the elderly population. Conventional methods for survival analysis assume independent censoring and ignore the competing events. However, there are some challenge issues using those conventional methods in the presence of competing risks. First, no one-to-one link between hazard function and cumulative incidence function (CIF), and Kaplan-Meier approach overestimates the cumulative incidence of the event of interest. Second, the effect of covariates on hazard rate cannot be directly linked to the effect of cumulative incidence (the risk). We will discuss two types of analyses in the presence of competing risk: Cause-specific hazard model and Fine-Gray subdistribution hazard model. Cause-specific hazard model directly quantify the cause-specific hazard among subjects who are at risk of developing the event of interest, while Fine-Gray subdistribution hazard model directly model the effects of covariates on the cumulative incidence function. The type of research questions (Association vs. Prediction) may guide the choice of different statistical approaches. We will illustrate those two competing risk analyses using the large national dataset from National Alzheimer's Coordinating Center (NACC). We will analyze the association between

baseline diabetes status and the incidence of dementia, in which death before the onset of dementia is a competing event.

ARE DRUGS THAT CAUSE DYSBIOSIS LONGITUDINALLY ASSOCIATED WITH COGNITIVE SCORES, COGNITIVE IMPAIRMENT, & DEMENTIA?

Nicholas Resciniti,¹ Matthew C. Lohman,² Alexander McLain,² Anwar Merchant,² and Daniela Friedman,² *1. University of Southern California, Los Angeles, California, United States, 2. University of South Carolina, Columbia, South Carolina, United States*

Recent research has examined how the microbiome may influence cognitive outcomes; however, there is a paucity of research understanding how medication associated with dysbiosis may be associated with cognitive changes. This study used data from the Health and Retirement Study and the Prescription Drug Study subset for adults 51 and older (n=3,898). Continuous (0-27) and categorical (cognitively normal=12-27; cognitive impairment=7-11; and dementia=0-6) cognitive outcomes were used. Prescriptions utilized were proton pump inhibitors, antibiotics, selective serotonin reuptake inhibitors, tricyclic antidepressants, anti-psychotics, antihistamines, and a summed dose-response measure. Linear mixed models (LMM) and generalized linear mixed models (GLMM) were used for continuous and binary outcomes. For the LMM model, the main effect for those taking one medication was insignificant; however, the interaction with time showed a significant decrease over time (β : -0.07; 95% confidence interval (CI): -0.14, 0.01). The mean cognitive score was lower for those taking two or more medications (β : -1.48; 95% CI: -2.70, -0.25), although the interaction with time was insignificant. GLMM results showed those taking two or medications had odds that are 612% larger (odds ratio (OR): 7.12; 95% CI: 3.03, 16.71) of going from cognitively healthy to dementia but the interaction with time showed decreased odds over time (OR: 0.92; 95% CI 0.86, 0.97). For cognitive impairment, those who took two or more medications had odds that were 45% larger (OR: 1.45; 95% CI: 1.05, 2.00) of going from cognitively healthy to cognitively impaired. This study indicated a dose-response aspect to taking medications on cognitive outcomes.

ASSOCIATION BETWEEN BODY WEIGHT CHANGE IN LATE LIFE AND RISK OF DEMENTIA: A POPULATION-BASED COHORT STUDY

Jie Guo,¹ Anna Marseglia,¹ Ying Shang,¹ Abigail Dove,¹ Giulia Grande,¹ Laura Fratiglioni,² and Weili Xu,¹ *1. Karolinska Institutet, Solna, Stockholms Lan, Sweden, 2. Karolinska Institutet 17175, Stockholms Lan, Sweden*

Background. Adiposity in midlife is a modifiable risk factor for dementia. However, the effect of adiposity in late-life on dementia remains unclear. We investigated the association of body mass index (BMI) and weight changes after age 60 with the incident dementia. Methods. Within the Swedish National Study on Aging and Care-Kungsholmen, 1,673 dementia-free participants with data on BMI/weight both at baseline and the 6-year follow-up were followed to detect subsequent incident dementia cases. BMI change was assessed as the percentage of the difference between BMI at

baseline and the initial 6-year follow-up and categorized into large (>10%) or moderate (5–10%) loss, stable (\leq 5%), and moderate (5–10%) or large (>10%) gain. Weight change (difference between weight at baseline and the 6-year follow-up) was categorized into large (>7.5 kg) or moderate (2.5–7.5 kg) loss, stable (\leq 2.5 kg), and moderate (2.5–7.5 kg) or large (> 7.5 kg) gain. Dementia was diagnosed following the DSM-IV criteria. Data were analyzed using Cox regression models. Results. During the follow-up (median 5.78 years), 102 incident dementia cases developed. BMI/weight change showed U-shaped associations with dementia. Compared with stable BMI, the hazard ratios (95% confidence intervals) of dementia were 2.93 (1.72–4.91) for large BMI loss and 2.61 (1.09–5.54) for large BMI gain. Similar results were observed for a large weight loss (2.92 [1.67–5.07]) or gain (2.95 [1.16–6.53]). These associations became stronger among participants carrying an ApoE ϵ 4 allele. Conclusion. Both large bodyweight loss and gain are associated with a higher risk of dementia, especially among ApoE ϵ 4 carriers.

ASSOCIATION OF BLOOD CELL PARAMETERS OF PERIPHERAL INFLAMMATION WITH BRAIN IMAGING MEASURES

Yuan Fang,¹ Kathryn Lunetta,¹ Claudia Satizabal,² Michael Alosco,³ Jesse Mez,³ Wendy Qiu,³ Margaret Doyle,⁴ and Joanne Murabito,⁵ 1. *Boston University School of Public Health, Boston, Massachusetts, United States*, 2. *Glenn Biggs Institute for Alzheimer's & Neurodegenerative Diseases, University of Texas Health Science Center, San Antonio, Texas, United States*, 3. *Boston University, Boston, Massachusetts, United States*, 4. *University of Vermont, Colchester, Vermont, United States*, 5. *Boston University, Framingham, Massachusetts, United States*

Neutrophil to lymphocyte ratio (NLR), red cell distribution width (RDW), and mean platelet volume (MPV), are easily measured circulating blood cell parameters that reflect chronic peripheral inflammation which increases risk for dementia and Alzheimer's disease (AD). We investigated the cross-sectional association between these blood cell parameters and brain MRI measures, including total cerebral brain volume (TCBV) as percentage of total intracranial volume (TCV) to correct for differences in head size, hippocampal volume (HPV) and log transformed white matter hyperintensity (WMH) volume, in the Framingham Heart Study (FHS) cohorts. We identified 2882 FHS participants 25 to 92 years of age (mean 59 years), 53% women, who attended an exam that included a complete blood cell count sample and received a brain MRI within five years of blood draw. We used linear mixed effect models to examine associations, adjusting for age, age², sex, education, cohort, time between blood draw and MRI, prevalent cardiovascular disease, C-reactive protein, APOE- ϵ 4 genotype and TCV for HPV and WMH, and accounting for familial correlation using a random effect. We observed significant ($p \leq 0.01$) associations between higher RDW and smaller TCBV, and between elevated NLR and larger WMH volume. Analysis on an older subgroup (age ≥ 60 years, mean 71 years, $n=1357$) demonstrated larger effect sizes and additional significance between increased RDW with smaller HPV. We conclude that chronic peripheral inflammation as measured by NLR and RDW associates with MRI measures of brain aging (TCBV,

HPV) and vascular brain injury (WMH) in FHS, with stronger impact in participants ≥ 60 years.

CHOOSING UNWISELY: DISSEMINATION NEEDS OF PRIMARY CARE PROVIDERS OF PATIENTS WITH ALZHEIMER'S DISEASE

Lee Lindquist,¹ Aylin Madore,² Stephanie Miller,² Theresa Rowe,¹ and Sara Bradley,¹ 1. *Northwestern University Feinberg School of Medicine, Chicago, Illinois, United States*, 2. *DBC Pri-Med, LLC, Boston, Massachusetts, United States*

Choosing Wisely is a well-known campaign to disseminate evidence-based clinical practices to providers and patients to drive care decisions, with geriatrics recommendations released in 2013. In December 2019, we aimed to determine what the dissemination needs of primary care providers were towards these recommendations. We developed common clinical scenarios with follow-up survey questions, relative to the care of people with Alzheimer's disease (AD) and utilizing Choosing Wisely geriatrics recommendations. The survey was distributed online to a national cohort of providers. Providers were also asked to rate their confidence level and rationale for clinical choices. Results were analyzed using mixed methodology, with constant comparative analysis utilized for qualitative responses. Nationally from 41/50 states, 211 providers responded, 72% female, with occupations of physician (36%, 77), advanced practice nurse (50%, 106) and physician assistant (13%, 28), with family practice (63%, 142) and internal medicine (20%, 43) the most prominent fields. Results revealed erroneous geriatric practices, including 1.) checking urinalysis for mental-status changes (55%, 116), 2.) treating asymptomatic bacteria with unnecessary antibiotics (59%, 124), 3.) placement of gastric tubes in end-stage dementia (11%, 23). Qualitative analysis of rationale for incorrect responses revealed knowledge misconceptions (e.g. feeding tube would help avoid aspiration). Confidence levels were high among providers as 75.9% rated themselves as above average, yet did not correlate to clinical errors. Choosing Wisely geriatrics recommendations are not being followed by some providers. Highly confident providers made errors similar to lower confident providers. New ways to disseminate geriatric recommendations are needed to improve the care of patients with AD.

DETECTING EARLY SIGNS OF ALZHEIMER'S DISEASE AND RELATED DEMENTIA ONSET FROM THE EHR

Karen Schliep,¹ Zachary Shepelak,¹ Nicolas Bitter,¹ Ramkiran Gouripeddi,¹ Truls Ostbye,² Ken Smith,¹ Samir Abdelrahman,¹ and Joanne Tschanz,³ 1. *University of Utah, Salt Lake City, Utah, United States*, 2. *Duke University, Durham, North Carolina, United States*, 3. *Utah State University, Logan, Utah, United States*

As dementia is widely under-detected, a predictive model using electronic health records (EHR) could provide a method for early screening to implement preventive strategies. There is limited research on using EHR to identify persons with Alzheimer's disease (AD) and related dementias (RD). In a data-driven approach, we used all ICD-9 diagnosis and CPT procedure codes from statewide inpatient, ambulatory surgery, and Medicare records, in addition to age at baseline and gender, to detect AD/RD from the Cache County Study on Memory

in Aging (1995–2009). After removing participants diagnosed with dementia at baseline ($n=335$), 3882 (82%) Cache County Study participants could be linked to inpatient, ambulatory surgery, and/or Medicare EHR records; 484 (12.5%) of these 3882 had incident all-cause dementia, with 308 (7.9%) having AD/AD comorbid with RD; and 176 (4.5%) having RD without AD. We removed participant's ICD-9 codes occurring after first AD/RD diagnoses. EHR features (~2000) along with gold-standard diagnoses as class labels were then used to train and detect AD and/or RD using a Gradient Boosting Trees machine learning algorithm. Models evaluated with nested cross-validation yielded AUCs of 0.70 for all-cause dementia, 0.69 for AD/AD comorbid with RD, and 0.67 for RD without AD. Key factors detecting AD/RD included age at enrollment, cardiovascular, metabolic, and kidney disease, and sleep disturbances, with feature importance varying by record type and time frame prior to dementia onset. Our findings suggest that a patient's health status up to 12 years prior may be useful in identifying individuals at-risk for dementia development.

EFFECTS OF CAREGIVER INTERVENTIONS FOR INFORMAL CAREGIVERS OF OLDER ADULTS WITH COGNITIVE DECLINE

Machiko Tomita, *University at Buffalo, State University of New York, Buffalo, New York, United States*

Objectives: To identify baseline factors and process factors, which indicate changes that are associated with caregiving confidence improvement attributed to caregiver support. **Methods:** An intervention study using 35 informal caregivers (ICG) of older adults (≥ 65 years old) with cognitive decline. Recipients of ICGs belonged to the Programs of All Inclusive Care for the Elderly (PACE). Interventions were occupational therapy (OT) support or education about illness and effective caregiving methods, which took place in ICGs' homes. OT interventions included training to reduce physical strain, and improve time and task organizations, and providing assistive devices). Caregiver confidence was measured using a Visual Analog Scale. Data were divided into two groups: improved confidence and decreased/no-change confidence. Eleven baseline data of care recipients (CRs) and ICGs as well as five process data were analyzed using logistic regression. **Results:** Baseline factors that differentiated the two groups were ICG's age, caregiving confidence level, and CR's cognitive status, of which classification accuracy was 94.3%. Only Zarit Buren Interview (ZBI) score was associated with caregiving confidence change, of which classification accuracy was 74.3%. Younger ICGs, lower cognition, and lower caregiving confidence among baseline factors, and improved ZBI among the process factors were associated with improved confidence. **Discussion:** Although our interventions prevented 65.7% of caregivers from declining their caregiving confidence, improving caregiving confidence was difficult while CRs' cognition continued to decline. However, this positive change was possible even CRs had moderate dementia, on average. Personal interventions may be necessary to improve caregiving confidence and reduce ICG's burden.

HORTICULTURE-BASED INTERVENTIONS TO ENHANCE HEALTH AND WELLBEING OF PEOPLE LIVING WITH DEMENTIA IN THE COMMUNITY

Theresa Scott,¹ Ying-Ling Jao,² Kristen Tulloch,¹ Yates Eloise,¹ and Nancy Pachana,¹ *1. The University*

of Queensland, St Lucia, Queensland, Australia, 2. Pennsylvania State University, University Park, Pennsylvania, United States

The majority of people living with dementia in the early and middle stages are cared for at home by family caregivers. Participation in meaningful activities is important for good quality of life. Recreation based on horticulture is beneficial for people living with dementia in residential settings, yet evidence within community settings is less clear. The aim of this research was to examine the existing evidence for the impact of using contact with nature, gardens and plants to enhance well-being of people living with dementia in the community. Our secondary aim was to explore the outcome domains and instruments that were employed in the existing research studies, to inform future research efforts and guide clinical practice. A systematic search was conducted covering several databases and gray literature. Original studies that examined group or individual horticulture-based activities or interventions were included. Of 2127 articles identified through searching, 10 were selected for full review. The findings reveal that horticulture-based intervention showed positive impacts on food intake, social interaction, and well-being in older adults with dementia. Some evidence shows that horticulture-based activities may alleviate stressful symptoms associated with living with dementia. Future research may further evaluate the effect of the interventions on cognitive function, physical function, and behavioral symptoms in a more rigorous intervention design.

IMPLICATIONS OF RACIAL DIFFERENCES IN THE SHIFTS IN THE SETTING OF CARE FOR ALZHEIMER'S DISEASE AND RELATED DEMENTIAS

Arseniy Yashkin,¹ Galina Gorbunova,² Anatoliy Yashin,² and Igor Akushevich,² *1. Duke University, Morrisville, North Carolina, United States, 2. Duke University, Durham, North Carolina, United States*

The prevailing setting of care has strong associations with the progression of a disease at time of first diagnosis, subsequent treatment, resulting health outcomes as well as both long-term and short-term costs. The care of Alzheimer's Disease (AD) and Related Dementias (ADRD) has been experiencing a shift from skilled nursing facility to home health care. However, changes in practice do not disseminate equally across the race/ethnicity spectrum of the U.S. and disadvantaged race/ethnicity-related groups often encounter differing conditions from those experienced by the majority. In this study, we calculated the race/ethnicity-related direct healthcare costs of individuals with AD and ADRD, stratified by care-provider structure (physician, inpatient, outpatient, skilled nursing facility, home health, hospice), and modeled the trends and the relative contributions of each setting over the 1991-2017 period using administrative claims from a 5% sample of Medicare beneficiaries. Inflation and the gradual switch of Medicare compensation to the HCC model between 2004 and 2007 were accounted for. We then applied an inverse probability weighting algorithm to propensity-score-match the AD/ADRD race/ethnicity-specific groups to Medicare beneficiaries to make them comparable in demographics and co-morbidity status but without AD/ADRD. Finally, we performed a comparison of the Medicare costs and associated survival within (AD/ADRD vs. No AD/ADRD) and between (Black vs. White vs. Hispanic) race/

ethnicity-related groups. Comparisons were done for: i) 1-year before; ii) 1-year after iii) years 2-11; iv) years 12-21 and v) years 22+ after an AD/ADRD diagnosis. We found significant race/ethnicity-related differences in costs and survival both before and after propensity score matching.

INCIDENCE OF MILD COGNITIVE IMPAIRMENT, CONVERSION TO PROBABLE DEMENTIA, AND MORTALITY

Yun Zhang,¹ Ginny Natale,² and Sean Clouston,³
 1. *Renaissance School of Medicine, Stony Brook University, Stony Brook, New York, United States*, 2. *Stony Brook University, Stony Brook, New York, United States*, 3. *Renaissance School of Medicine, Stony Brook University, Renaissance School of Medicine, Stony Brook University, New York, United States*

Background: Few studies have jointly estimated incidence of MCI, conversion to probable dementia, and mortality. **Methods:** We used data from six waves of the National Health and Aging Trends Study (2011-2016). Multivariable-adjusted multi-state survival models (MSMs) were used to model incidence upon accounting for misclassification. **Results:** A total of 6,078 eligible NHATS participants 65 years of age and older were included (average age: 77.49 ± 7.79 years; 58.42% females; 68.99% non-Hispanic White). Incidence of MCI was estimated to be 41.0 [35.5, 47.3]/1,000 person-years (PY). Participants converted to probable dementia at a high rate of 241.3 [189.6, 307.0]/1,000 PY, though a small number also reverted from MCI to cognitively normal. Education was associated with lower incidence of MCI and probable dementia, but increased mortality in those with MCI. There were also substantial racial and ethnic disparities in the incidence of MCI and dementia. **Conclusions:** Our results underscore the relatively common incidence of and conversions between MCI and dementia in community-dwelling older Americans and uncover the beneficial impact of education to withstand cognitive impairment before death.

MACHINE LEARNING-BASED PREDICTIVE MODELS OF BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS OF DEMENTIA

Eunhee Cho,¹ Sujin Kim,² Seok-Jae Heo,³ Jinhee Shin,¹ Byoung Seok Ye,² Jun Hong Lee,⁴ and Bada Kang,⁵ 1. *Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 3. *Yonsei University Graduate School, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 4. *National health insurance service Ilsan hospital, Goyang, Kyonggi-do, Republic of Korea*, 5. *Mo-Im Kim Nursing Research Institute, Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Models predicting the occurrence of specific types of behavioral and psychological symptoms of dementia (BPSD) can be highly beneficial for its early intervention and individualized care planning. Using a machine learning approach, this study developed and validated predictive models of the occurrence of BPSD, categorized into seven subsyndromes, among community-dwelling older adults with dementia in South Korea. BPSD diary was used to measure BPSD and the state of unmet needs daily. We measured sleep and activity levels using actigraphy, and stress and fatigue using a portable heart rate variability analyzer. We developed predictive models and

conducted cross-validation using training data that consisted of the first two wave dataset, and then validated the models using wave 3 test data. To deal with imbalanced datasets, we used Synthetic Minority Oversampling Technique (SMOTE), an over-sampling method. Categorical variables were pre-processed using target encoding. We then compared the machine-learning models with logistic regression. The area under the receiver operating characteristic curve (AUC) scores of the support vector machine (SVM) models for the wave 3 test data showed a similar or greater value than logistic regression models across all BPSD subsyndromes. The SVM model (AUC = 0.899) had an AUC value greater than that of the logistic regression model (AUC = 0.717), particularly for hyperactivity symptoms. Machine learning algorithms, especially SVM models, can be used to develop BPSD prediction models to help identify at-risk individuals and implement symptom-targeted individualized interventions.

MODIFIABLE RISK FACTORS OF BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS IN PEOPLE WITH DEMENTIA

Shinae Seo,¹ and Meghan Mattos,² 1. *University of Virginia School of Nursing, Charlottesville, Virginia, United States*, 2. *University of Virginia, School of Nursing, Charlottesville, Virginia, United States*

Over ninety percent of people with dementia (PWD) experience behavioral and psychological symptoms, known to increase burden on care providers and healthcare systems. The purpose of this integrative review was to examine the modifiable risk factors of behavioral and psychological symptoms of dementia (BPSD) at the individual, caregiver, and environmental levels. An electronic database search was performed using PubMed, CINAHL[EBSCO], Web of Science, and PsycINFO from 2010-2020. Search terms included “dementia” AND (“Behavioral” OR “Behavioural” OR “Psychological” OR “Neuropsychiatric”) AND “symptoms” AND (“Independent Living” OR “Community Dwelling” OR “Community Living” OR “Living at Home” OR “Ageing in Place.” The search yielded 1,121 articles, and 14 articles were included in this review. Among the 14 articles, there were 11 modifiable risk factors presented across the individual, caregiver, and environmental levels. Individual-level factors included the presence of affective disorder, low quality of life, and leisure dysfunction. The modifiable caregiver-level factors included relationship with PWD, frequency of contact, caregiver burden, distress, frustration level, caregiver as a resource for PWD, and quality of dyadic relationship. One environmental factor, the presence of pandemic disease (e.g., COVID 19), was identified. This review presents the modifiable factors that contribute to the varied symptoms and multi domains of BPSD. Further research is necessary to determine whether, and to what degree, interventions targeting individual, caregiver, or environmental risk factors may reduce BPSD for PWD, caregivers, and providers within the community setting.

MUSIC INTERVENTIONS FOR EARLY-STAGE COGNITIVE DECLINE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Jennie Dorris,¹ Stephen Neely,² and Juleen Rodakowski,¹ 1. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*, 2. *Carnegie Mellon University, Pittsburgh, Pennsylvania, United States*

Older adults in the early stages of Alzheimer's and dementia deserve effective modalities that support their cognition, emotional well-being, and social engagement. Music has demonstrated potential to support these critical outcomes through its ability to simultaneously stimulate multiple areas of the brain and induce neuroplasticity. We reviewed randomized controlled trials for studies that specifically utilized active music-making interventions for older adults with early-stage cognitive decline to assess their effects on cognition, emotional well-being, and social engagement. Additionally, this review categorized the specific music activities employed by each intervention. We conducted searches on Medline (Ovid), APA PsycInfo (Ovid) CINAHL (Ebsco), and Embase (Elsevier). Our search yielded 285 potential studies. We analyzed 19 studies with 1,387 participants for potential effect sizes and intervention ingredients. Of the 19 studies, eight studies, recruiting a total of 460 participants, were used to conduct a random-effects meta-analysis to assess the effect of music on cognition. Meta-analytic aggregation of effect sizes showed that music had a modest positive effect on cognition compare with the control conditions (SMD= 0.26; P= 0.008; 95% confidence interval, 0.07, 0.45; I2= 5%). The musical activities of 1) singing and/or playing pre-composed songs and/or 2) creating music in the moment were utilized in the protocols. This research demonstrates that active music-making supports cognition for older adults with early-stage cognitive decline. Future music programs should consider inclusion of pre-composed songs, as well as music creation, to better understand the power for music to provide critical support for a rapidly growing segment of the population.

PREDICTORS OF BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS IN COMMUNITY-DWELLING OLDER ADULTS WITH DEMENTIA

Bada Kang,¹ Eunhee Cho,² Sujin Kim,³ Sinwoo Hwang,⁴ Eunji Kwon,⁴ Seok-Jae Heo,⁵ Jun Hong Lee,⁶ and Byoung Seok Ye,³ 1. *Mo-Im Kim Nursing Research Institute, Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 3. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 4. *Korea Armed Forces Nursing Academy, Daejeon, Taejon-jikhalsi, Republic of Korea*, 5. *Yonsei University Graduate School, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 6. *National health insurance service Ilsan hospital, Goyang, Kyonggi-do, Republic of Korea*

Although disclosing the predictors of different behavioral and psychological symptoms of dementia (BPSD) is the first step in developing person-centered interventions, the current understanding is limited as it considers BPSD as a homogenous construct, not accounting for its heterogeneity. Therefore, this study explored the predictors of BPSD subsyndromes, and built prediction models for these subsyndromes in community-dwelling older adults with dementia in Korea. This prospective study consisted of a two-wave dataset. We fit the generalized linear mixed models using Wave 1 data (N = 145) and then validated them using Wave 2 data (N = 59). BPSD and their proximal factors were

assessed on a daily basis using diaries written by family caregivers. Sleep and activity levels were objectively measured using actigraphy. The amount of nighttime sleep hours was significantly associated with next-day sleep and nighttime behaviors (OR = 0.87; p = 0.005), with the amounts of energy expenditure showing significant association with euphoria/elation (OR = 0.02; p = 0.019). All subsyndromes except euphoria/elation were found to be significantly associated with either hunger, thirst, urination, or bowel movement; with all BPSD showing a significant association with environmental changes. We also found several background factors, including premorbid personality and taking sedatives as predictors for specific subsyndromes. The area under the receiver operating characteristic curve scores for the data were greater than 0.9 and 0.8 in Waves 1 and 2, respectively, across all subsyndromes. Prediction models for BPSD will help in the development of symptom-targeted, individualized interventions.

PRESCRIPTION PATTERNS OF ANTI-DEMENTIA AND PSYCHOTROPIC DRUGS IN PEOPLE LIVING WITH DEMENTIA IN CHINA

Zhang Yingyang,¹ Hao Luo,² Gloria HY Wong,² Terry YS Lum,² Celine Chui,² Ian C.K. Wong,² and Huali Wang,³ 1. *The University of Hong Kong, Hong Kong, Hong Kong*, 2. *The University of Hong Kong, Hong Kong, Hong Kong*, 3. *Peking University Institute of Mental Health (Sixth Hospital), Beijing, Beijing, China (People's Republic)*

Pharmacotherapy of dementia is a critical intervention for managing symptoms of and slowing progression of dementia. However, evidence on prescribing patterns of dementia medications and their associated factors in China is lacking. This study aimed to examine prescribing rates of anti-dementia and psychotropic drugs, and investigate factors associated with prescription of anti-dementia drugs and its co-prescription with psychotropic drugs in China. We used data from the Clinical Pathway for Alzheimer's Disease in China study, an eight-week multi-center registry study that was conducted in tertiary hospitals between Nov 12, 2012, and Jan 31, 2013. Anti-dementia and psychotropic drugs were coded according to the Anatomical Therapeutic Chemical codes. Logistic regressions were performed to examine factors associated with prescription patterns after controlling for demographic and clinical characteristics of people living with dementia and caregivers' characteristics. A total of 746 participants were included in this study, of which almost 80% of participants were prescribed anti-dementia drugs, and one-third were prescribed at least one psychotropic drug. The concomitant prescription rate of anti-dementia and psychotropic drugs was 24.3%. Logistic regression results showed that first consultation, dementia subtypes, dementia severity, functioning level, and having symptoms of psychosis and apathy were significantly associated with anti-dementia drug prescription. Frontotemporal dementia, worse functioning level, psychosis, agitation, and depression were significantly associated with co-prescription of anti-dementia and psychotropic agents. Practices of dementia prescriptions generally conformed with clinical guidelines in tertiary hospitals in China, while prescription of anti-dementia and psychotropic medications mainly depended on clinical symptoms of patients with dementia.

THE EFFECTS OF MULTI-COMPONENT INTERVENTIONS ON COGNITION: A SYSTEMATIC REVIEW

Sangwoo Ahn, and Joel Anderson, *University of Tennessee at Knoxville, Knoxville, Tennessee, United States*

Given the lack of a cure for Alzheimer's disease (AD), the number of people with AD is expected to surge unless the onset is delayed. Although there have been efforts to examine the effects of single-domain neuroprotective interventions on cognition, no conclusive results have been found so far. Due to the multifactorial causes of AD, interventions combining multiple neuroprotective components may induce more beneficial effects. However, there are few comprehensive reviews evaluating the effects of multi-domain programs on cognition. Thus, the purpose of this systematic review was to evaluate the effects of currently available multi-component interventions on cognition such as global cognition, episodic memory, and/or executive function affected early in AD. The literature search was conducted using PubMed, CINAHL, Web of Science, Scopus, and PsycINFO up to September 2020. Of the 1,445 articles located, 17 met eligibility criteria ($n = 10,056$, mean age = 72.8 years). According to the Effective Public Health Practice Project Quality Assessment Tool for Quantitative Studies, 8 and 9 studies had strong and moderate overall quality, respectively. The effect sizes of each included study were calculated using Cohen's d . Multi-component interventions comprising physical activity, cognitive exercise, cardioprotective nutrition, and/or cardiovascular health consultation/education exerted beneficial effects on cognition (very small to moderate effect sizes; Cohen's $d = 0.16$ to 0.77). Clinically, health care providers are recommended to consider those elements to potentially stave off AD. There is a pressing need for researchers to identify optimally effective doses of neuroprotective multi-component interventions.

TRAJECTORIES OF COGNITIVE FUNCTION AND ASSOCIATED FACTORS IN COMMUNITY-DWELLING OLDER ADULTS: A PROSPECTIVE STUDY

Zimu Wu,¹ Robyn Woods,¹ Elsdon Storey,² Trevor Chong,² Raj Shah,³ Suzanne Orchard,¹ Anne Murray,⁴ and Joanne Ryan,¹ *1. Monash University, Melbourne, Victoria, Australia, 2. Monash University, Monash University, Victoria, Australia, 3. Rush, Rush University Medical Center, Illinois, United States, 4. Hennepin HealthCare Research Institute, Hennepin HealthCare, Minneapolis, Minnesota, United States*

There is variability in cognitive aging between individuals. This study aimed to investigate cognitive aging trajectories, the associated modifiable factors, and the association of these trajectories with dementia. Community-dwelling older adults ($n=19,114$) without dementia or major cognitive impairment at inclusion were followed for up to 7 years, with regular standardized cognitive assessments. Group-based (multi-) trajectory modeling identified distinct cognitive trajectories. Structural equation modeling ($n=16,018$) was used to analyze the associated predictors. Four to seven trajectories were identified per cognitive domain, with generally stable trajectories. Improvement in verbal fluency and minor psychomotor slowing were common. Substantial decline in global cognition and episodic memory were observed

in a small proportion of individuals. The highest proportions of dementia cases were in trajectories with major decline in global cognition (56.9%) and memory (33.2%). A number of sociodemographic characteristics, health behaviors and chronic conditions were either directly or indirectly associated with cognitive change in older adults. This study found that some individuals appear resilient to cognitive decline even with advancing age, and that factors that promote healthy cognitive aging are not simply the absence of factors which confer risk for decline.

Session 9070 (Poster)

Alzheimer's Disease II (HS Poster)

A PHASE I TRIAL ASSESSING LOMECEL-B INFUSION IN INDIVIDUALS WITH ALZHEIMER'S DISEASE: STUDY DESIGN AND RATIONALE

Kevin Ramdas,¹ Keyvan Yousefi,² Ben Hitchinson,³ Lisa McClain-Moss,³ Liliana Diaz,³ Barry Baumel,⁴ Joshua Hare,³ and Anthony Oliva,³ *1. Longeveron, Inc., Miami, Florida, United States, 2. Longeveron Inc., Miami, Florida, United States, 3. Longeveron, Inc, Miami, Florida, United States, 4. University of Miami, Miami, Florida, United States*

Alzheimer's disease (AD) is an irreversible neurodegenerative disorder characterized by memory loss and persistent cognitive dysfunction which significantly compromises quality of life. Brain inflammation is a prominent feature of AD pathology. Lomecel-B which is derived from culture-expanded medicinal signaling cells (MSCs) have immuno-modulatory capacity and control inflammation and the cytokine production of lymphocytes. The primary objective of this study was to evaluate the safety of Lomecel-B infused intravenously in individuals with AD. Safety was monitored by examining vital signs, physical and neurological exams, laboratory tests (hematology, coagulation, blood chemistry, and urinalysis). This was a multicenter phase 1 double-blinded, placebo controlled trial initiated with a safety run in phase of 3 individuals followed by a randomized phase of 28 individuals. During the safety run-in phase all subjects were treated with low dose Lomecel-B no less than 5 days apart, and evaluated for safety. In the randomized phase, subjects were treated with either low or high dose Lomecel-B or Placebo in a 2:2:1 randomization ratio. The study enrolled adults aged 50-80 years diagnosed with AD via confirmatory brain MRI and PET scan and a MMSE score of 18-24. Safety and efficacy assessments were completed at 30, 90, 180, 270 and 365 days. We describe the design and rationale for this phase 1 trial with the primary objective of assessing the safety of Lomecel-B on adults with AD. The secondary efficacy measurements included ADAS-Cog 11, MMSE, TMT, UPSIT, GDS, blood biomarkers and numerous quality of life questionnaires.

CARDIOMETABOLIC RISK FACTORS PREDICT EXECUTIVE FUNCTION SCORES IN HIGH-RISK INDIVIDUALS

Joshua Gills,¹ Megan Jones,¹ Anthony Campitelli,¹ Sally Paulson,² Erica Madero,³ Jennifer Myers,³

Jordan Glenn,³ and Michelle Gray,¹ 1. *University of Arkansas at Fayetteville, Fayetteville, Arkansas, United States*, 2. *University of Arkansas at Fayetteville, Cincinnati, Ohio, United States*, 3. *Neurotrack Technologies, Redwood City, California, United States*

Alzheimer's disease (AD) is expected to triple by 2050, affecting 16 million Americans. As a result, it is essential to combat this alarming increase in cognitive impairment through early detection. Cardiometabolic risk factors have shown to be associated with higher risk of AD. The purpose of this study was to determine if cardiometabolic risk factors could predict executive function scores in a high-risk population. Fifty (60.9±8.8 years) high-risk adults (classified by the Australian National University Alzheimer's Disease Risk Index) were enrolled in this study. Participants completed a 6-minute walking test, venous blood draw, blood pressure measurement, and the digit coding symbol test (DCS). Results were examined through a multiple linear regression with DCS as the dependent variable and age, sex, total cholesterol, high-density lipoprotein (HDL), low-density lipoprotein (LDL), glucose, 6-minute walking test, systolic blood pressure (SBP), and diastolic blood pressure (DBP) as predictor variables. The model explained 42% of the variance of DCS ($p = .04$) with SBP (45%; $p = .003$) as a significant predictor. LDL ($p = .087$) and DBP ($p = .123$) accounted for 24% and 22% of the variance for this model, respectively. These results suggest cardiometabolic risk factors predict executive function values in high-risk individuals. Higher SBP was significantly associated with lower DCS scores indicating SBP as a valuable tool for practitioners when evaluating cognitive decline. Further research should expand sample size and track values longitudinally to substantiate these claims.

CAREGIVER SINGING INTERVENTION: DO EMOTIONS AND RESISTANCE DIFFER BETWEEN VASCULAR DEMENTIA AND ALZHEIMER'S?

Lena Hammar,¹ Gabriella Engström,² and Anna Swall,² 1. *Mälardalen University / Dalarna University, Västerås, Västmanlands Lan, Sweden*, 2. *Dalarna University, Falun, Dalarnas Lan, Sweden*

Persons with dementia in residential care commonly express resistance of aggressiveness. Caregivers Singing (CS) - when caregivers sing for or together with persons with dementia during caring, has shown to reduce these expressions and increase communication and cooperation. Previous studies of CS have included both persons with Alzheimer's disease (AD) and persons with Vascular dementia (VD), but no studies have been done focusing on possible differences regarding these diagnoses. As disabilities and symptoms differ between these diagnoses, the emotions and expressions, such as resistance may differ regarding response to CS. This pilot study aims to describe emotions and resistiveness to care among persons with vascular or Alzheimer's disease. Participants were five persons with AD and five persons with VD living at two different nursing homes. Video observations (VIO) occurred with them and their caregivers during morning care situations four times without CS and four times with CS. In all, 80 VIOs were rated using the Observed Emotion Rating Scale and the Resistiveness to Care Scale. These were then analyzed with descriptive statistics. Results revealed that for both persons with AD and VD,

the positive emotion pleasure were never observed without CS while with CS it increased for both groups. In contrast to the positive emotion effect of CS, the negative emotions and resistiveness decreased more for persons with VD than for persons with AD. For persons with VD, the number of observations without anger increased, while observation without anger or anxiety/fear for persons with AD remind the same.

COMPARISON OF COGNITIVE INTERVENTION DELIVERY FORMATS IN PATIENTS WITH DEMENTIA-A NETWORK META-ANALYSIS

Yue Sun,¹ and Zhi-wen Wang,² 1. *School of Nursing, School of Nursing, Peking University, Beijing, China (People's Republic)*, 2. *Peking University Health Science Center, Beijing, Beijing, China (People's Republic)*

Cognitive intervention has been shown to be effective to delay cognitive decline in older adults with dementia. However, whether cognitive intervention could be effectively delivered in individual, group, telephone, guided self-help and unguided self-help formats remains unclear. Pubmed, Embase, Cumulative Index to Nursing and Allied Health Literature (CINAHL), CINAHL, the Cochrane Central Register of Controlled Trials, Web of science, China National Knowledge Infrastructure database, Chinese Biomedical Literature database and Wan Fang database were systematically searched. 3419 records were extracted, quality assessed, and double-blind screened by 2 authors. Totally 51 studies were included which enrolled 3388 participants. Network meta-analysis (NMA) was conducted to evaluate the relative effects and rank probability of different cognitive intervention delivery formats. For older adults with dementia, guided self-help, group and individual cognitive intervention delivery formats appeared effective in improving the cognitive function, while telephone and unguided self-help were not significantly inferior to control condition. Guided self-help had the highest probability of being the best treatment among the five cognitive intervention delivery formats. Health-care professionals should apply personalized cognitive intervention format based on individual condition and preferences.

COMPARISON OF METHODS TO CLASSIFY ADRD IN CLAIMS AND CANCER REGISTRY DATA

Vinit Nalawade,¹ James Murphy,¹ Tim Schempp,² Melissa Yakuta,² Alison Moore,¹ Paul Gilbert,² and Melody Schiaffino,² 1. *University of California, San Diego, La Jolla, California, United States*, 2. *San Diego State University, San Diego, California, United States*

Alzheimer's disease and related dementias (ADRD) affects 10.3% of older Americans (65+), among these 15-30% go on to be diagnosed with cancer. The highest burden of ADRD is experienced by Latino/a (12.2%) and African-American (13.8%) older adults. Older patients with pre-existing ADRD are less likely to receive guideline-concordant cancer care due to lack of consideration of cognitive status, and underestimation of ADRD diagnosis is an issue in secondary data. Our study compares two validated algorithms for classifying ADRD in a sample of cancer patients, the NCI-Charlson and CMS-Chronic Conditions Warehouse (CCW) index. We used existing claims from NCI's SEER-Medicare linked database (2004-2013, N=37,932). Patients were

selected based on cancer diagnosis at any stage with at least 36 months of data prior to diagnosis to identify ADRD. We analyzed breast, lung, prostate, cervix, head & neck(HNC), and colorectal(CRC) cancers(CA). We found a prevalence of 2.8% (9549 cases of ADRD+CA) using the NCI-index compared with a prevalence of 5.6% (18989 cases) with the CCW-index. ADRD+CA numbers differed significantly in all cancers for all races, however, we observed the greatest magnitude of difference among Latino/a and African-American patients. The NCI index significantly underestimated prevalence compared with the CCW: 1.21% vs 3.28% Breast; 2.29% vs 4.60% CRC; 2.88% vs 6.44% Lung; 1.36% vs 8.62% Prostate, and 4.21% vs 11.61% HNC. Our findings suggest a need to develop validated algorithms for classification, using an evidence-base generated by incorporating information and decision-making theories from the expertise of clinicians currently diagnosing ADRD using clinical assessments in diverse populations.

EATING DIFFICULTIES AMONG OLDER ADULTS WITH DEMENTIA IN SOUTH KOREAN LONG-TERM CARE FACILITIES: A SCOPING REVIEW

Eunju Choi,¹ Dukyoo Jung,² and Kyuri Lee,¹ *1. College of Nursing, Ewha Womans University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Ewha Womans University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

This study aims to synthesize existing literature concerning eating difficulties among older adults with dementia in long-term care facilities. A scoping review, using the framework proposed by Arksey & O'Malley (2005) and improved and supplemented by Levac et al. (2010), was conducted. Literature was searched from five bibliographic databases—Research Information Sharing Service (RISS), Korean studies Information Service System (KISS), National Digital Science Library (NDSJ), Korean Medical Database (KMBASE), DataBase Periodical Information Academic(DBPia), Google Scholar, and gray literature. Literature selection and characteristics were approved by two independent reviewers, using pre-tested forms to determine final inclusion. Eventually, 111 articles from 2012–2020 were identified, and the 11 articles were used for the final analysis. We found that primarily utilized Eating behavior scale (EBS) and Edinburgh feeding evaluation in dementia scale (EdFED) had utilized as measurement tools for evaluating eating behavior. The most common factors related to eating behavior of older adults with dementia included cognitive and physical functions in the individual domain, the caregiver's attitude toward eating in the inter-individual domain, and types of meal in the environmental domain. Therefore, it is essential to develop measurement tools that reflect the eating behavior of older adults with dementia, a comprehensive understanding of the eating behavior of old adults with dementia, and create effective interventions that can be implemented in the specificity of long-term care facilities in Korea. The results of this analysis are intended to be used as basis to develop a meal support programs for older adults with dementia.

FACTORS DRIVING THE TRANSITION OF ALZHEIMER'S DISEASE PATIENTS TO INSTITUTIONAL LONG-TERM CARE

Heather Davila,¹ Guneet Jasuja,² Lauren Moo,³ Madhuri Palnati,² Qing Shao,² Quanwu Zhang,⁴

Amir Abbas Tahami Monfared,⁵ and Donald Miller,² *1. Iowa City VA Healthcare System; University of Iowa Carver College of Medicine, Iowa City, Iowa, United States, 2. VA Bedford Healthcare System, Bedford, Massachusetts, United States, 3. VA Bedford Health Care System, Bedford, Massachusetts, United States, 4. Eisai Inc, Woodcliff Lake, New Jersey, United States, 5. Eisai Inc., Woodcliff Lake, New Jersey, United States*

Progression of Alzheimer's disease (AD) may ultimately lead to costly institutional long term care (ILTC) so its avoidance is often a goal of care management. We studied predictors of AD patients transitioning to ILTC in the Veterans Affairs healthcare system (VA). We identified 30,017 Veterans at least 50 years old, with \geq ICD-9/10-CM diagnosis codes for AD on separate days, with first AD code in 2013-2018, at least 2 years of prior continuous VA service use, and no prior ILTC. Patients who subsequently transitioned to ILTC (cases) were matched to other AD patients with the same time since first AD code but no ILTC (controls) (median of 13 months; mean age of 80.2 years). The 8,261 matched sets were split randomly to a training sample, where logistic and random forest regressions were used to develop models, and a validation sample, where final models were evaluated. Predictors of ILTC initiation included measures of (1) poor health, such as high morbidity counts (Elixhauser score of 15+, odds ratio=1.31) and weight loss (1.29), (2) heavy service use, such as hospitalization (2.25) and home health care (1.54), and (3) dementia symptoms, such as a diagnosis code for dementia not-otherwise-specified recorded well before the AD code (1.93), functional/mobility difficulties (1.35), and lifestyle or psychosocial problems (1.53). The full model C statistic was 0.78. Transition to ILTC in AD patients is driven by many factors, including comorbidities, need for acute care, nonspecific symptoms of dementias, and functional challenges. Targeted interventions may delay transitions to ILTC.

GAIT SPEED AND GRIP STRENGTH ARE PREDICTORS OF COGNITIVE DECLINE AND DEMENTIA IN OLDER INDIVIDUALS.

Suzanne Orchard,¹ Joanne Ryan,¹ Galina Polekhina,¹ Elsdon Storey,² Raj Shah,³ Trevor Chong,² Anne Murray,⁴ and Robyn Woods,¹ *1. Monash University, Melbourne, Victoria, Australia, 2. Monash University, Monash University, Victoria, Australia, 3. Rush, Rush University Medical Center, Illinois, United States, 4. Hennepin HealthCare Research Institute, Hennepin HealthCare, Minneapolis, Minnesota, United States*

Lower gait speed and grip strength are common in older adults. However, the results of lower motor function on cognitive outcomes have been mixed. We examined the longitudinal association between baseline slow gait speed and weak grip strength, alone and in combination, with risk of incident dementia or cognitive decline in a cohort of older adults. Participants (n=19,114) aged 70 and over (65 if U.S. minority) without documented evidence of dementia, significant cognitive impairment, physical disability or previous cardiovascular disease at baseline, were recruited from community settings. Incident dementia was adjudicated by an expert panel using DSM-IV criteria. Incident cognitive decline was defined as a persistent intra-individual decline in score

of >1.5 SD from baseline on any of the cognitive tests. Using cox proportional hazard models, slow gait speed at baseline was associated with an increased risk of dementia (63%) and cognitive decline (43%), over a median 4.7 years. Weak grip strength was not as strong a predictor, but was also associated with risk (43% and 11%, respectively). Both outcomes showed higher risk for dementia than cognitive decline. There was no gender-specific interaction. When considered together (adjusted for one another), gait speed and grip strength were both independently associated with cognitive decline and dementia. The synergistic association of these physical measures, each of which is readily administered in the clinic or home, serve as effective early markers of increasing risk of cognitive decline and incident dementia and thus, should be considered for routine health assessments for older adults.

HIPPOCAMPAL VOLUME IS SMALLER IN FEMALE DOUBLE CARRIERS OF TWO STRONGEST AD GENETIC RISK FACTORS

Svetlana Ukraintseva,¹ Vladimir Popov,² Konstantin Arbeev,¹ Hongzhe Duan,² Olivia Bagley,¹ Alexander Kulminski,² and Anatoliy Yashin,¹ 1. *Duke University, Durham, North Carolina, United States*, 2. *DUKE UNIVERSITY, Durham, North Carolina, United States*

Genetic risk factors for Alzheimer's disease (AD) may facilitate AD-related changes in the brain long before AD clinical manifestation. While APOE4 was linked to a reduced hippocampal volume (HV) in a number of studies, the impact of rs2075650, another polymorphism strongly associated with AD, on HV is less clear. The rs2075650 (in TOMM40) is only in moderate to low LD with APOE4, and may have independent effects on HV or interact with APOE4. We studied associations of rs2075650 (G allele, risk factor for AD), rs429358 (C allele, proxy for APOE4), and their combinations, with right HV measured by MRI, among 10,738 women and 9,775 men aged 60-75, from UK Biobank. We found that right HV was significantly ($p < 0.02$) smaller in women who carry both AD risk variants (rs2075650(G) and rs429358(C)), than in non-carriers of both of these variants, while having only one risk variant (G or C) didn't clearly affect HV. The studied associations didn't reach statistical significance in men. Our results suggest that rs2075650(G) and rs429358(C) may contribute synergistically to a reduction in hippocampus volume, in females only, and support the role of interactions between genetic risk factors for AD in sex differences in preclinical biomarkers of AD pathology.

HYPERTENSIVE DISORDERS OF PREGNANCY AND RISK OF ALZHEIMER'S DISEASE, VASCULAR DEMENTIA, AND OTHER RELATED DEMENTIA

Karen Schliep,¹ Yue Zhang,¹ Joanne Tschanz,² Jennifer Majersik,¹ Julio Facelli,¹ and Michael Varner,¹ 1. *University of Utah, Salt Lake City, Utah, United States*, 2. *Utah State University, Logan, Utah, United States*

Several recent studies have examined whether hypertensive disorders of pregnancy (HDP) are associated with an increased risk for Alzheimer's disease (AD) and other related dementias (RD) with conflicting findings. Limitations to prior studies include lack of assessing risk by dementia subtype, inadequate sample sizes, and not fully exploring the role of mid-life factors. We performed a retrospective matched cohort study among women with >1 singleton pregnancy

(1939–2013) using the Utah Population Database. HDP-exposed women ($n=19,989$) were one-to-two matched with unexposed women ($n=39,679$) by 5-year age groups, year of childbirth (within 1 year), and parity (1, 2, 3, 4, ≥ 5) at the time of the pregnancy. HDP pregnancies were complicated by preeclampsia (62%), gestational hypertension (34%), and eclampsia (4%). Women with a history of HDP had a higher hazard of all-cause dementia (HR=1.37; 95% CI: 1.26, 1.50) compared to women without a history of HDP after adjustment for maternal age, year of childbirth, and parity. The hazard doubled after additionally accounting for pre-pregnancy BMI (HR=2.31; 95% CI: 1.24, 4.32). Stratifying by dementia subtype, we found HDP to be associated with a higher hazard of vascular dementia (HR=1.64; 95% CI: 1.19, 2.26) and other related dementia (HR=1.49; 95% CI: 1.34, 1.65) but not Alzheimer's disease (HR=1.04; 95% CI: 0.87, 1.24) after accounting for competing risks. Mid-life hypertension and stroke were found to have the greatest mid-life impact, mediating 43% and 41% of dementia risk, respectively, highlighting women who may most benefit from close surveillance and early preventive and clinical interventions.

INFORMATION AND COMMUNICATION TECHNOLOGY USE IN COMMUNITY-DWELLING PERSONS LIVING WITH DEMENTIA

Kyung Hee Lee, Ji Yeon Lee, and Bora Kim, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Although many persons living with dementia still remain living in the community, they encounter many difficulties due to cognitive and physical impairment. Information and Communication Technology (ICT) could be helpful to protect persons living with dementia from risky events and monitor changes in physical function. This study aimed to review studies regarding ICT usage to monitor physical activity and safety in community-dwelling persons living with dementia. We searched quantitative studies that utilized ICT to monitor physical activity and safety published from 2011 to 2020 through five databases; 24 studies were included in the systematic review. Most studies (79%) were observational studies and conducted in North America or Europe (75%). In terms of ICT usage, the most frequently used type was a wearable device (96%); data such as physical activity, gait, and circadian rhythms were gathered. The ICT data were utilized for: 1) comparing ICT data within dementia group or with normal cognition group; 2) exploring a relationship with other variables in observational studies; 3) measuring an outcome of the experimental studies; and 4) determining feasibility of a sensor itself. Less than half of the studies met all five criteria in quality assessment. We found the ICT is being used in various ways in research for community-dwelling persons living with dementia. However, we are uncertain about the effectiveness of ICT use and the quality of studies. Future studies with rigorous study design are needed to provide better evidence for ICT use in persons living with dementia.

LONGITUDINAL ASSOCIATION OF FALL RISK FOR COMMUNITY DWELLING ELDERLY WITH AND WITHOUT ADRD

Pallavi Tyagi, *School of Public Health, University of Maryland, University of Maryland, College Park, Maryland, United States*

Falls amongst elderly with ADRD and are a major cause of functional impairment and increased mortality. The

primary purpose of this study was to examine if fall status of community dwelling elderly residents with and without ADRD differs over a four year period and additionally does receipt of rehabilitation in any year modifies this association. National Health and Aging Trends Study (NHATS) data from 2015-2018 was used and sample consisted of participants age 65 and older who were community dwellers. Baseline characteristics of individuals in ADRD (n= 264) and non-ARDR group (n=2,971) was compared using chi square statistic. A generalized estimating equation model (multivariate logistic regression) was used to estimate odds ratio of falls in the two groups, adjusted for sociodemographic and clinical conditions that are predictors of fall risk. At baseline, ADRD group comprised of older, frail individuals who reported increased use of assistive device (AD) and presence of depression. Those in the non-ARDR group at baseline had significantly decreased odds for falls however no statistically significant change was observed for fall status over four years in the two groups (non-ARDR vs ADRD) and this association was not modified by receipt of rehabilitation. Those who used AD, had depression and received rehabilitation had increased odds for falls however no differences were found for those who lived alone and were frail. Future studies should examine the bi-directional interplay between falls and rehabilitation in elderly with ADRD with inclusion of other predictors of fall risk to study their unique characteristics.

LUNG FUNCTION AND DEMENTIA RISK IN THE ATHEROSCLEROSIS RISK IN COMMUNITIES (ARIC) STUDY

Srishti Shrestha,¹ Xiaoqian Zhu,¹ Stephanie London,² Kevin Sullivan,³ Pamela Lutsey,⁴ B. Gwen Windham,¹ Michael Griswold,³ and Thomas Mosley,³ 1. *University of Mississippi Medical Center, Jackson, Mississippi, United States*, 2. *National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina, United States*, 3. *The University of Mississippi Medical Center, Jackson, Mississippi, United States*, 4. *School of Public Health, University of Minnesota, Minneapolis, Minnesota, United States*

Poor lung function has been linked with adverse neurocognitive outcomes including dementia, but evidence from well-designed prospective studies is limited. We therefore examined the association between lung function, as measured by forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC), and dementia risk in 12,688 participants of the ARIC study, a prospective study of adults aged 46-70 years (at index visit, mean age =57y, 45% male, 76% White) from four US communities. Lung function was assessed in 1991-1992 (index visit, 76% normal, 16% obstructive, and 8% restrictive lung function), and dementia was ascertained through 2019 via in-person assessments, telephone interviews, and medical record surveillance, with adjudication of dementia with all in-person exams. A total of 2452 developed dementia over 30 years of follow-up. We used Cox proportional hazards model to estimate hazard ratio (HR) and 95% confidence intervals (CI), adjusting for potential confounders (socio-demographics, behavioral factors, cardiovascular risk factors, APOE ε4). Higher FEV1 and FVC were associated with reduced dementia risk [(HR: 0.86, 95%CI: 0.78-0.98, per 1L increase in FEV1) and (HR:

0.86, 95%CI: 0.80-0.93 per 1L increase in FVC)]. Compared to normal lung function, restrictive disease was associated with elevated dementia risk [(HR: 1.19, 95%CI: 1.01-1.41), n=168 dementia cases]; HR for obstructive disease, though modestly elevated (1.09, 95%CI: 0.96-1.24, n=713 dementia cases), was not statistically significant. Our findings of decreased dementia risk with better lung function may have important implications in reducing burden of dementia that is attributable to environmental exposures and associated lung function impairment.

PREVALENCE OF MCI AND DEMENTIA PRIOR TO INCARCERATION

Randall Kuffel,¹ Amy Byers,² Brie Williams,² Richard Fortinsky,³ John Boscardin,² Yixia Li,⁴ and Lisa Barry,⁵ 1. *San Francisco Veterans Affairs Health Care System, San Francisco, California, United States*, 2. *University of California, San Francisco, San Francisco, California, United States*, 3. *University of Connecticut School of Medicine, Farmington, Connecticut, United States*, 4. *San Francisco VA Health Care System, San Francisco, California, United States*, 5. *University of Connecticut Center on Aging, Farmington, Connecticut, United States*

As the number of older, incarcerated persons increases, prevalence of dementia and mild cognitive impairment (MCI) in this population will likely grow, with implications for healthcare costs and advance care planning within the prison setting. This study is the first to determine the prevalence of dementia or MCI in later-life adults prior to incarceration. We leveraged a national cohort of Veterans aged 50+ whose most recent incarceration was ≤10 years in length and who were released between 10/1/2012 and 9/30/2018 (N=17,962). We linked VA and CMS healthcare records to determine diagnosis of dementia or MCI within 3 years prior to incarceration. The overall sample had a mean age of 62.4 (±7.6) years at the start of their incarceration, were largely male (97%), and were 65% White and 30% Black. Before incarceration, 445 (2.5%) and 152 (0.8%) Veterans were diagnosed with dementia and MCI, respectively. Compared to those without a diagnosis of dementia or MCI prior to incarceration, those with dementia or MCI were older at incarceration start (66.1 [±8.3] vs. 62.3 [±7.9]), had more chronic medical conditions (4.0 [±2.2] vs. 2.2 [±1.9]), were more likely to experience homelessness (21.6% vs. 9.1%), have a TBI (24.5% vs. 9.1%), and have serious mental illness (81.7% vs. 49.1%). All comparisons were significant (p<.001). Our findings indicate that later-life adults with dementia or MCI are being incarcerated. Improved understanding of pathways linking cognitive impairment to later-life incarceration is needed to both prevent unnecessary incarceration and to help provide appropriate healthcare for this vulnerable group.

RISK FACTORS OF SLEEP DISTURBANCE IN OLDER ADULTS WITH DEMENTIA: AN ACTIGRAPHY-BASED VALIDATION STUDY

Jinhee Shin,¹ Eunhee Cho,¹ Bada Kang,² Sujin Kim,³ Sinwoo Hwang,⁴ Eunji Kwon,⁴ and Seok-Jae Heo,⁵ 1. *Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Mo-Im Kim Nursing*

Research Institute, Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 3. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 4. Korea Armed Forces Nursing Academy, Daejeon, Taejon-jikhalsi, Republic of Korea, 5. Yonsei University Graduate School, Seoul, Seoul-t'ukpyolsi, Republic of Korea

Sleep disturbance is a common and significant symptom experienced by older adults with dementia. Early detection and timely treatment of sleep disturbance are critical to prevent adverse consequences including decreased quality of life for persons with dementia and increased caregiver burden. While direct observations and sleep diaries are often unreliable, actigraphy is a cost-effective method in measuring sleep problems in older adults with dementia and provides reliable and rich sleep data. Therefore, this study aimed to examine sleep disturbance objectively measured by actigraphy and its risk factors in community-dwelling older adults with dementia in Korea. This is a prospective study consisting of a two-wave dataset. The model was fitted using Wave 1 data (n=151) and then validated using Wave 2 data (n=59). Independent variables were demographics, cognitive and physical function, depressive symptoms, physical activity level, and neuropsychiatric symptoms measured by Neuropsychiatric Inventory(NPI), and clinical factors including dementia type, sedative use, and comorbidities. Sleep disturbance was defined as less than six nighttime sleep hours and sleep efficacy less than 75%. Using the Youden's Index, the sample was dichotomized into sleep disturbance group (n=83) and sound sleep group (n=68). The results of the generalized linear mixed model showed that the risk factors for sleep disturbance included vascular dementia, age, step count, and having three neuropsychiatric symptoms (i.e., delusions, depression, and disinhibition). Individuals with dementia at risk for sleep disturbance should be identified to prioritize early prevention strategies and individualized interventions. Particularly, management of delusion, depression, disinhibition is critical in preventing disturbed sleep.

SOURCES OF POSITIVITY IN THE DAILY LIFE OF FAMILY CAREGIVERS OF PERSONS WITH DEMENTIA

Kyungmi Lee,¹ Breannlyn Archer,² Kaitlyn Cox,² and Carolyn Pickering,² 1. University of Alabama at Birmingham, Hoover, Alabama, United States, 2. The University of Alabama at Birmingham, Birmingham, Alabama, United States

Family caregivers often experience fatigue, burnout, and health complications yet also enjoy many aspects of caregiving that may benefit their well-being. This study identifies positive aspects of caregiving in the daily life experiences of dementia family caregivers in order to inform interventions to support caregivers' well-being. This case study entails a secondary analysis of open-ended question data obtained from 165 family caregivers who answered daily diaries over 21 days (n = 2841 responses). We used content analysis to organize and elicit thematic categories from the data collected in response to the question "what was the best part of your day." A final 762 responses were selected as meeting the "care" criteria for the study, with an inter-rater reliability of 91.6%. Data analysis revealed three major sources of daily positive aspects including: caregiver-focused, patient-oriented,

and support-system based. The analysis also revealed seven different kinds of daily positive aspects, such as getting to enjoy time with the care recipient or getting to accomplish other non-caregiving tasks. Many of the positive aspects of caregiving reported were enabled by social support, but they were ultimately from how they utilized that support (e.g., getting alone time) that provided the positivity. The findings of this study demonstrate the important role social support plays in caregiving, as well as highlights other possible intervention targets to create easier, more positive days for family caregivers.

THE RELATIONSHIP BETWEEN NEUROPSYCHIATRIC SYMPTOMS, NIGHTTIME BEHAVIORS, AND ALZHEIMER'S DISEASE CSF BIOMARKERS

Meina Zhang,¹ Young-Eun Cho,² and Chooza Moon,²

1. University of Iowa, Iowa City, Iowa, United States,

2. University of Iowa, university of Iowa, Iowa, United States

Alzheimer's disease (AD) commonly involves neuropsychiatric symptoms (NPS), such as nighttime behaviors (or sleep disturbance), hallucination, delusion, or mood changes. However, it is unclear how NPS and sleep disturbances are correlated with AD biomarkers. The purpose of this analysis was to examine how NPS and nighttime behaviors are associated with AD CSF biomarkers by cognitive status. A total of 1,667 subjects' (mean age = 69.4 SD=9.3, 48 % (808) were male) data from the National Alzheimer's Disease Coordinating Center (NACC) were used, including subjects with dementia (n = 577), mild cognitive impairment (MCI, n = 363), cognitive impairment but not MCI (n = 47), cognitive impairment due to Alzheimer's etiology (n= 608), and normal cognition (n = 680). The nighttime symptoms, number, and severity of NPS were assessed using the Neuropsychiatric Inventory Questionnaire Quick Version (NPI-Q). Cerebrospinal fluid (CSF) samples were analyzed for A β 42, dft5 t-tau, p-tau. We used generalized linear models to explore the associations accounting for age, sex, APOE4 alleles, and BMI. We found the number of NPS were associated with A β 42 (p = 0.042) in individuals with MCI, impaired, or dementia due to Alzheimer's etiology. Yet, the number of NPS were not associated with t-tau or p-tau in individuals with and without dementia. The severity of NPS including nighttime symptoms were not associated with biomarkers. Our results could suggest that the number of NPS can be reflected by higher CSF A β 42 levels in the individuals with Alzheimer's etiology. Future longitudinal analyses are warranted to understand the causal relationships.

TIME-VARYING INSOMNIA SYMPTOMS AND INCIDENCE OF COGNITIVE IMPAIRMENT AND DEMENTIA AMONG OLDER US ADULTS

Nicholas Resciniti,¹ Bezawit Kase,² Valerie Yelverton,² and Matthew C. Lohman,² 1. University of Southern California, Los Angeles, California, United States, 2. University of South Carolina, Columbia, South Carolina, United States

There is conflicting evidence regarding the association between insomnia and the onset of mild cognitive impairment (MCI) or dementia. This study aimed to evaluate if time-varying insomnia is associated with the development of MCI and dementia. Data from the Health and Retirement Study (n = 13,833) from 2002 to 2014 were used (59.4% female).

The Brief Insomnia Questionnaire was used to identify insomnia symptoms compiled in an insomnia severity index, ranging from 0 to 4. In the analysis, participants' symptoms could vary from wave-to-wave. Dementia was defined using results from the Health and Retirement Study (HRS) global cognitive assessment tool. Respondents were classified as either having dementia, MCI or being cognitively healthy. Cox proportional hazards models with time-dependent exposure using the counting process (start-stop time) were used for analysis. For each one-unit increase in the insomnia symptom index, there was a 5-percent greater hazard of MCI (HR = 1.05; 95% CI: 1.04–1.06) and dementia (HR = 1.05; 95% CI: 1.03–1.05), after fully adjusting. Using a nationally representative sample of adults aged 51 and older, this study found that time-varying insomnia symptoms are associated with the risk of MCI and dementia. This highlights the importance of identifying sleep disturbances and their change over time as potentially important risk factors for MCI and dementia.

WHICH COGNITIVE BEHAVIORAL THERAPY FORMATS WORK FOR DEPRESSION IN DEMENTIA FAMILY CAREGIVERS ?

Yue Sun,¹ and Zhi-wen Wang,² 1. *School of Nursing, School of Nursing, Peking University, Beijing, China (People's Republic)*, 2. *Peking University Health Science Center, Beijing, Beijing, China (People's Republic)*

Cognitive behavioral therapy (CBT) has been shown to be effective to delay cognitive decline for family dementia caregivers (DCs). However, whether cognitive intervention could effectively reduce depression through internet, group, telephone, individual, unguided self-help and combined formats remains unclear. Pubmed, Embase, Cumulative Index to Nursing and Allied Health Literature (CINAHL), the Cochrane Central Register of Controlled Trials, Web of science, China National Knowledge Infrastructure database, Chinese Biomedical Literature database and Wan Fang database were systematically searched. A total of 34 studies were included in our analysis based on a series of rigorous screenings, which comprised 3577 DCs. We conducted a network meta-analysis (NMA) to evaluate the relative effects and rank probability of different CBT delivery formats. A series of analyses and assessments, such as the pairwise meta-analysis and the risk of bias, were performed concurrently. Compared with controls, internet, telephone, and individual showed the largest improvement on depressive symptoms, whereas the unguided self-help delivery format was less effective. Internet delivery formats had the highest probability among the five CBT delivery formats. Our study indicated that the internet might be the best delivery formats for reducing the depression of family DCs. The findings from our study may be useful for policy makers and service commissioners when they make choices among different CBT delivery formats.

Assessment

AGING ACROSS THE LIFE COURSE: RESEARCH COLLECTIONS AVAILABLE FROM THE NATIONAL ARCHIVE OF COMPUTERIZED DATA ON AGING

James McNally, *University of Michigan, Ann Arbor, Michigan, United States*

The creation and maintenance of sustainable data archives can be challenging, but it offers clear advantages. Properly curated data can be used by multiple researchers, testing a variety of hypotheses, and increasing the return on investment to the expensive process of data collection. Having an internally managed archival system also provides greater control and autonomy in the equitable distribution of data resources. This process ensures all researchers will have full use of the data for original research, teaching, and new directions once the data leaves the control of the local investigator's control. This poster reviews the advantages of having a local strategy geared toward the preservation and sharing of gerontological research data. Using the National Archive of Computerized Data on Aging (NACDA) as a working example, the poster offers an overview of collections at NACDA. Using our metadata tools and variable search database, NACDA can identify studies in its collections that examine aspects of aging and health among adults during their lifecourse. Many of the studies are longitudinal or repeat measure cross-sectional studies. We are also able to identify studies that focus on aging that are not maintained by NACDA but which are available to interested researchers. Using a strategy of archival preservation combined with a strong focus on productive research Innovation in Aging, NACDA has amassed data and metadata covering a wide array of studies worldwide that address the aging lifecourse. Because our collections are multinational, we share these data at no cost to interested users worldwide

COGNITIVE STATUS & DEMENTIA SEVERITY IN CVLT-II-SF FORCED CHOICE RECOGNITION: IMPLICATIONS FOR EFFORT ASSESSMENT

Karl Grewal,¹ Michaella Trites,² Megan O'Connell,¹ Andrew Kirk,¹ Stuart MacDonald,² and Debra Morgan,¹ 1. *University of Saskatchewan, Saskatoon, Saskatchewan, Canada*, 2. *University of Victoria, Victoria, British Columbia, Canada*

Effort testing is critical to neuropsychological practice, including dementia assessment. Questions exist around whether cognitive status or impairment severity impacts effort test performance in this population. Presently, we examined whether scores on an embedded effort test - the California Verbal Learning Test II Short Form (CVLT-II-SF) Forced Choice Recognition (FCR) - differed across diagnostic cognitive status groups and how severity of impairment modulated test performance. In a sample of memory clinic patients, three cognitive status groups were identified: subjective cognitive impairment (SCI; n = 92), amnesic mild cognitive impairment (a-MCI; n = 18), and dementia due to Alzheimer's Disease (AD; n = 70). Significant group differences in FCR performance were observed using one-way ANOVA (p < .001), with post-hoc analysis indicating the AD group performed significantly worse scores than the other groups. Using multiple regression, FCR performance was modelled as a function of cognitive status, impairment severity indexed MMSE, and their interaction, with a parallel analysis for the Clinical Dementia Rating Sum of Boxes (CDR-SOB) scores as an alternate severity measure. Results yielded significant main effects for MMSE (p = 0.019) and cognitive status (p = 0.026), as well as a significant interaction (p = 0.021). Thus, increases in impairment severity disproportionately impaired FCR performance for persons

with AD, calling into question research-based cut scores for effort determination in dementia contexts. Corresponding CDR-SOB analyses were non-significant. Future research should examine whether CVLT-II-SF-FCR is an appropriately specific inclusion in a best-practice testing battery for evaluating effort in dementia populations.

EXAMINING STEREOTYPE THREAT IN NEUROPSYCHOLOGICAL TESTING: A USABILITY AND USER EXPERIENCE PILOT STUDY

Jazlyn Armendariz,¹ Sarah Hwang,¹ Giovanna Garrido Blanco,² Maria Pena,³ and Thomas Chan,¹ 1. *California State University Northridge, Northridge, California, United States*, 2. *California State University Northridge, Chanhassen, Minnesota, United States*, 3. *California State University Northridge, Pacoima, California, United States*

Stereotype threat is defined as the situational predicament when people feel at risk of conforming to social stereotypes. Correspondingly, stereotype threat may negatively impair a persons' working memory and cognitive abilities during neuropsychological tests due to hyper awareness of negative stereotypes. Moreover, it is critical to test the usability and the user experience of application-based neuropsychological assessments within diverse aging adult populations. In this pilot study, verbal expressions of feeling pressure to succeed, within a diverse population of young adults, were examined while taking an application-based neuropsychological assessment. Data was collected from 15 self-identified respondents (i.e., 7 Latinx, 5 Asian, 3 Bi-racial). Before beginning the assessment, 8 out of 15 participants exhibited self-handicapping behaviors such as offering explanations of mental exhaustion due to work and lack of sleep. Literature suggests these expressions are related to the onset of anxiety prior to taking cognitive tests, and contribute to potentially offering an excuse in anticipation of poor performance. Additionally, 3 out of 15 participants noted that even though the tasks were simple, they felt unintelligent because they did not complete the tasks to their best abilities (e.g., "I felt stupid. It was simple"). Findings from this pilot support the negative impact stereotype threats have on feelings of inadequacy and increase of anxiety levels among ethnic minorities in testing settings. Further emphases on examining the usability and user experience of application-based tests are needed, particularly within a diverse population of aging adults to facilitate more culturally competent neuropsychological testing experiences.

FINDING FACTORS IN FOOTFALLS: EXPLORING THE FACTOR STRUCTURE OF GAIT IN OLDER ADULTS.

Michael Willden,¹ Josh Palmer,² Kristina Kowalski,³ Sandra Hundza,¹ and Stuart MacDonald,¹ 1. *University of Victoria, Victoria, British Columbia, Canada*, 2. *University of Victoria, University of Victoria, British Columbia, Canada*, 3. *University of Calgary, University of Calgary, Alberta, Canada*

Gait is a reputed marker of global health spanning various bodily systems (MacDonald et al., 2017) and is a robust predictor of deleterious age-related outcomes (Van Kan et al., 2009). However, the sheer number of individual gait variables employed as predictors in the existing literature can

obscure interpretations. To address this issue, researchers have explored the factor structure of gait indicators to explain variance in age-related gait performance, identifying disparate models characterized by three to five underlying latent gait constructs comprised of 8 to 23 indicators (Hollman et al., 2011; Lord et al., 2013). Beyond this heterogeneity, additional limitations characterizing this literature include solutions that assume statistical independence among gait constructs, as well as inclusion of severely multicollinear indicators. Using data from the Healthy Minds Healthy Bodies (HMHB) study, the present research focused upon replicating and contrasting previous factor analytic efforts. HMHB participants (n=128) were healthy community-dwelling adults (Mage=72.81±5.24 years; female=100). Gait indicators from a GAITRite computerized walkway were selected according to a priori theoretical rationale, compatibility with previous studies, and consideration of multicollinearity. Gait factor structure was initially analyzed using principal component analysis. Results indicate the presence of three latent gait domains reflecting pace, rhythm, and variability, accounting for over 82.4% of the variance in gait performance. Current proceedings involve implementing confirmatory factor analysis to compare competing gait models. Findings will address disparities across factor models in the gait literature, as well as discuss the optimal number of factors for describing the underlying dimensionality of gait.

MEASUREMENT INVARIANCE IN THE ASSESSMENT OF MOOD BETWEEN AMERICAN AND MEXICAN COMMUNITY STUDIES

Manuel Herrera, and Daniel Paulson, *University of Central Florida, Orlando, Florida, United States*

The Health and Retirement Study (HRS), a principal source for American public health research, has numerous global sister studies. Harmonization efforts seeking to establish measurement equivalence amongst these various datasets, is a critical prerequisite to cross-cultural research. Given well-known cultural variability in depressive symptom endorsement, the purpose of this study was to assess measurement invariance in a brief mood measure used in the HRS and the Mexican Health and Aging Study (MHAS). Total sample size using both groups was 15,319 participants (10,931 HRS; 4,388 MHAS) who were 65 and older from Waves 6 to 13 in the HRS and Waves 1 to 4 in the MHAS. MPlus Version 8.4 was used to conduct CFA analyses of measurement invariance. A contemporary approach with categorical data calls for examining threshold invariance first while establishing configural invariance, before examining invariance tests of thresholds, loadings, and intercepts in a second step. Results were that measurement invariance was not supported in this series of two steps with four out of six indices showing model fit in the first model and none of the indices showing model fit in the second model. These findings implied that there were differences in ways of responding to the brief mood measure between HRS and MHAS participants at the conceptual level. Thus, comparisons based on these measures may result in misleading findings and should be interpreted very conservatively. This study adds to the growing body of literature guiding harmonization efforts from the Program on Global Aging, Health and Policy.

MEASUREMENT INVARIANCE OF NEGATIVE AFFECT IN AMBULATORY ASSESSMENTS OF YOUNG-OLD AND OLD-OLD ADULTS

Oliver Schilling,¹ Anna Lücke,² Martin Katzorreck,³ Ute Kunzmann,⁴ and Denis Gerstorff,⁵ 1. *University of Heidelberg, Heidelberg, Baden-Württemberg, Germany*, 2. *Heidelberg University, Heidelberg, Baden-Württemberg, Germany*, 3. *University of Leipzig, Leipzig, Sachsen, Germany*, 4. *Leipzig University, Leipzig, Sachsen, Germany*, 5. *Humboldt University of Berlin, Humboldt University of Berlin, Brandenburg, Germany*

Gero-psychological research increasingly considered intense longitudinal assessments of momentary affect to address affective aging. In particular, many studies employed negative emotion item lists for ambulatory assessments of negative affect. However, frequent self-reports on emotion items within short time intervals might change alertness towards and perception of one's emotional experiences. From an item-response-theoretic point of view, this might impair the stability of item functioning in terms of item discrimination between levels of affectivity and item severity (difficulty). Thus, we examined measurement invariance of negative emotion items commonly used for ambulatory assessments of negative affect. Ambulatory assessments from the EMIL study, obtained over seven consecutive days at six occasions per day from 123 young-old (aged 66-69) and 47 old-old (86-89) adults, were analyzed. Respondents self-reported on 13 negative emotion items, using a 0-100 slider to express the degree to which they felt the respective emotion. We ran multilevel structural equation models with Bayes estimation to analyze variability of negative affect factor loadings, item intercepts, and measurement error variances across repeated measures, thus checking for metric, scalar, and strict factorial invariance. For all sets of parameters, the findings do not strongly support measurement invariance, but point at partial invariance for item subsets. Taking on literature suggesting that criteria for invariance testing should not be too restrictive to meet pragmatic measurement equivalence requirements, further analyses and our conclusions focus on strategies that might allow for acceptable degrees of differential item functioning, enabling reliable analyses of intra-individual short-term variability in negative affect.

MEASUREMENT OF CENTRE OF PRESSURE USING THE WII BALANCE BOARD IN OLDER ADULTS WITH SIMULATED VISUAL IMPAIRMENT

Berkley Petersen, Caitlin Murphy, Aaron Johnson, and Karen Li, *Concordia University, Concordia University, Quebec, Canada*

Postural stability is a complex skill dependent upon the coordination of motor, sensory and cognitive systems. The purpose of this project was therefore to explore how older adults' balance performance is impacted by increased cognitive load, hearing loss, and simulated vision loss. Twenty-eight older adults between the ages of 50 and 93 years ($M = 73.86$, $SD = 10.43$) were tested. Participants underwent standard sensory acuity and cognitive functioning tests. The balance trials varied as a function of cognitive load and visual challenge resulting in five conditions: (1) eyes closed, (2) normal vision clear goggles (NV) (3) simulated low vision (20/80) goggles (LV) (4) LV and math task, (5) NV and math task. Postural

stability was assessed with three key center of pressure parameters: total path length (TPL), anterior-posterior amplitude (APA) and medial-lateral amplitude (MLA). A mixed-model ANOVA using hearing acuity as a covariate revealed significant effects of complexity in sway amplitude: (APA: $p < .017$; MLA: $p < .020$), while TPL approached significance ($p < .074$). T-tests revealed significant ($p < .05$) decreases in balance performance across all 3 centre of pressure parameters when comparing single task NV to dual-task NV, NV vs. eyes closed and single task NV vs. LV dual-task. There were significant positive correlations between hearing acuity and balance (MLA) under single task NV ($r = .491$) and LV conditions ($r = .497$). Results suggest the attentional demands from increased cognitive load and sensory loss lead to decreases in older adults' single- and dual-task balance performance.

Session 9080 (Poster)

Attitudes and Perceptions Toward Technology

ADAPTING TRAINING AND USE OF AN APPLICATION FOR COGNITIVELY IMPAIRED OLDER ADULTS AMIDST COVID-19

Francesca Falzarano,¹ Sarah Weingast,² Gabriel Gladstone-Groth,³ Marco Ceruso,⁴ and Sara Czaja,⁵ 1. *Weill Cornell Medicine, Douglaston, New York, United States*, 2. *Weill Cornell Medicine, Weill Cornell Medicine, New York, United States*, 3. *Weill Cornell Medicine, New York, New York, United States*, 4. *Weill Cornell Med, New York, New York, United States*, 5. *Weill Cornell Medicine/Center on Aging and Behavioral Research, New York, New York, United States*

The emergence of COVID-19 and social distancing requirements have resulted in disruptions to daily life, reduced opportunities for social engagement, and diminished resource access for millions of older adults. Individuals with cognitive impairments (CI) are particularly vulnerable to risk for social isolation. This presentation will discuss the PRISM-CI pilot trial, which aims to examine the feasibility and potential efficacy of the PRISM-CI software system on enhancing connectivity and quality of life among a diverse sample of 50 older adults aged 65 and over with a CI. PRISM-CI, adapted from the PRISM system (developed by the Center for Research and Education on Aging and Technology Enhancement) for this population, is intended to support social engagement, memory, and access to resources and information. We will present data regarding the feasibility and perceived value of PRISM-CI and discuss the challenges, and strategies used, to adapt the PRISM-CI trial during the pandemic. We used a multi-modal approach to provide remote training and specialized tablet instruction that includes individualized training sessions tailored to individuals' learning needs, hobbies, and prior technology use. The adapted protocol also involves the use of remote access software for troubleshooting. We will also discuss how participant feedback guided the inclusion of additional features, such as Zoom videoconferencing and virtual library access, for the PRISM-CI application. Finally, we will demonstrate how the adaptation of the PRISM-CI protocol holds promise for the use of flexible, remote technology approaches to reach socially isolated older adults to foster psychosocial well-being.

CO-DESIGN OF TECHNOLOGY DRIVEN SELF-MANAGEMENT WITH OLDER ADULTS: AN INTERNATIONAL APPROACH

Danielle Saney,¹ Alessandro Pollini,² Sandra Suijkerbuijk,³ Regina Krijger,⁴ and Arlene Astell,⁵ 1. *University of Toronto/Toronto Rehabilitation Institute, Toronto, Ontario, Canada*, 2. *BSD Design, Rome, Lazio, Italy*, 3. *Vilans, Utrecht, Utrecht, Netherlands*, 4. *Careyn, Utrecht, Utrecht, Netherlands*, 5. *University of Toronto, Toronto, Ontario, Canada*

There has been an emergence in technology applications (apps) aimed at addressing needs amongst older adults and persons with cognitive impairment (PwCI). Despite the ubiquity of these apps, utilization is low, primarily due to a lack of involvement of PwCI and the perception that these apps have little motivational value. Engaging PwCI in creative processes such as co-design could lead to the creation of apps that better meets the needs of this population. The current study applies a user-centered, participatory approach to involve PwCI in the design of a new self-management and coaching app, RESILIEN-T. Co-design workshops were held with 12 PwCI across Italy, Netherlands and Canada; structured as four modules: (1) introduction and expectation setting, (2) user analysis, (3) storytelling, and (4) collaborative design. Based on interviews with PwCI, stories of individuals which reflect the target population were created (personas) and the solutions to the needs of these personas were discussed. Information about participant's interests, computer proficiency and self-rated cognitive decline were collected. Participants were asked to try 10 existing apps and provided feedback on the design, usability and functionality. Lastly, participants were shown a prototype for RESILIEN-T and provided feedback based on the personas that they helped create. Co-design activities revealed that personalization is crucial for adherence. Aspects of physical and social activity, nutrition and cognition were most important to participants. Participants found many apps that are recommended for older adults do not appear age appropriate and seem condescending. These findings were common across PwCI from various nations.

EXERCISE AND ATTITUDE FOR EXOSKELETONS: THE MEDIATION OF TECHNOLOGY ANXIETY AND PERCEIVED USEFULNESS

Seolah Lee,¹ Do Kyung Yoon,¹ Miseon Kang,¹ Kwang Joon Kim,² YoonMyung Kim,¹ Yun Mook Lim,¹ and Hey Jung Jun,¹ 1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The present study aimed to examine the effects of regular exercise on attitude towards using exoskeletons and the mediating effects of technology anxiety and perceived usefulness among Korean older adults. Data was collected through online recruitment in February 2021. The sample comprised 310 people (Age: 65-89, M=70.18, SD=4.58) who did not report dementia. The dependent variable was the attitude towards using technology, especially lower limb exoskeleton robots for exercise. The independent variable, regular exercise, was coded as a binary variable. The mediating variables were technology anxiety and perceived usefulness

measured by the sum of three questions about exoskeleton robots, respectively. Gender, age, education level, and household income were included as control variables. The mediating effect was estimated by serial path analysis and bootstrapping (model fit indices: $\chi^2=18.400$, $df=8$, $p<0.05$, RMSEA=0.065, CFI=0.973, TLI=0.940, SRMR=0.044). Results showed the total effect of regular exercise was significant ($B=1.253$, $p<0.01$) and the total indirect effect of it was significant ($B=1.540$, $p<0.001$). There was no significant direct effect of regular exercise on the attitude towards using technology. The association between regular exercise and the attitude of using technology was completely mediated by perceived usefulness ($B=1.439$, $CI=0.569-2.358$, $p<.01$). Although technology anxiety had no mediating effect alone, the serial mediating effect via the path from technology anxiety to perceived usefulness was significant ($B=0.119$, $CI=0.004-0.332$, $p<.05$). This study will be the first empirical study to examine the effects of health habits by expanding the senior technology acceptance model for older adults in Korea.

FACTORS AFFECTING THE INTENTION TO USE EXOSKELETON FOR EXERCISE AND THE MODERATING EFFECT OF FRAILTY

Choi Bomi,¹ Susanna Joo,² Changmin Lee,¹ Chang Oh Kim,³ Yun Mook Lim,¹ and Hey Jung Jun,¹ 1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea*, 3. *Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

This study aims to find relevant factors influencing the intention to use exoskeletons for exercise (IEE) among older adults and to analyze the moderating effect of frailty. The sample of this study is 310 people (65 or older) without cognitive impairment who completed an online survey. The intention to use exoskeletons was measured with three questions from the Senior Technology Acceptance Model (STAM). Potential relevant factors comprise sociodemographic characteristics, physical and psychological health, exercise, attitude towards aging, and social relationship. Linear regression analyses showed that depressive symptoms, regular exercise, attitude towards aging, and social participation were significantly related to IEE. People with more depressive symptoms and a negative attitude towards aging are more likely to have a higher level of IEE. People who exercise regularly and actively participate in social activities showed a higher level of IEE. Subgroup analyses were performed based on the frailty status measured with Korean Groningen Frailty Indicator (K-GFI). Among people without frailty ($N=177$), regular exercise, and social participation were positively related to IEE. The number of chronic diseases and social participation was positively related to IEE among people with frailty ($N=133$). The results of this study implied that poor health conditions lead to an increased need for exoskeletons. The results of this study also suggested that exercise and social participation work as facilitating factors in the context of gerontechnology acceptance. Results of subgroup analyses suggested that influencing factors on IEE can vary depending on the physical functional status.

FRAILITY STATUS MODERATES THE ASSOCIATION BETWEEN SELF-EFFICACY AND THE INTENTION TO TECHNOLOGY USE

Miseon Kang,¹ Si Young Song,¹ Inhye Jung,¹ YoonMyung Kim,¹ Chang Oh Kim,² and Hey Jung Jun,¹
 1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

This study examined how the status of frailty moderated the association between the self-efficacy about gerontechnology use and the intention to use gerontechnology (IUG) among Korean older adults. In this study, gerontechnology devices referred to exoskeleton robots for exercise. The data was collected through an online survey in February 2021, and 324 Korean older adults aged 65 and above were included in the analysis (Women: 50.9%, Men: 49.1%). The dependent variable was the intention to use gerontechnology from the Almere model (Heerink, 2010) and the independent variable was self-efficacy about gerontechnology use from the Senior Technology Acceptance Model (Chen & Chan, 2014). Both were measured as continuous variables. The moderating variable was the status of frailty (Non-frail=0, Frail=1). Age, gender, education level, and log-transformed household income were controlled for. Multiple linear regression to examine moderation effect was conducted using PROCESS Macro model 1. The findings showed that frailty status moderates the association between self-efficacy and IUG among Korean older adults. Concretely, the higher self-efficacy about gerontechnology use, the lower IUG for non-frail Korean older adults. However, the main effect of self-efficacy was non-significant for the frail sample. Even though self-efficacy has been known to affect the variables related to technology use or acceptance positively, the results suggest that there may exist differences in research results depending on participants' health status. The type of gerontechnology devices may also have affected the results. Further exploration is needed to the interaction effects of potential influencing factors on the gerontechnology acceptance model.

GENDER DIFFERENCES IN ONLINE HEALTH-RELATED SEARCH BEHAVIORS AMONG OLDER ADULTS

Matthew Picchiello,¹ Payton Rule,² Tina Lu,² and Brian Carpenter,³ 1. *Washington University in St. Louis, University City, Missouri, United States*, 2. *Washington University in St. Louis, St. Louis, Missouri, United States*, 3. *Washington University in St. Louis, Saint Louis, Missouri, United States*

Nearly 60% of older adults use the internet for health-related reasons. Some studies have demonstrated differences in the frequency at which men and women perform various online activities. However, few studies have investigated gender differences in health-related search behaviors (HRSB). The purpose of this study was to examine differences in self-reported HRSB between older men and women. A total of 47 older adults (M age = 66.6, 55% female, 87% White) completed a survey assessing perceived usefulness and trust in the internet for health-care information, types of websites used, and reasons for looking up health information. Independent samples t-tests revealed that, compared to women, men regard the internet as more useful in helping them make health

care decisions ($t(45) = 2.715$) and as a more trustworthy source ($t(45) = 2.24$, $p's < 0.05$). Men were more likely to get health information through sources affiliated with educational institutions ($\chi^2(1) = 3.9$) and government agencies ($\chi^2(1) = 8.8$), whereas women were more likely to use social media, ($\chi^2(1) = 4.3$, $p's < 0.05$). Lastly, men were more likely to use the internet to learn about information on medical procedures ($\chi^2(1) = 5.1$), while women were more likely to learn about alternative treatments ($\chi^2(1) = 4.9$, $p's < 0.05$) online. As 72.3% of participants indicated the internet as their first source for health information, interventions geared towards enhancing HRSB for older adults are needed, especially for older women whose HRSB may make them particularly vulnerable to misinformation.

HUMAN FACTORS LINKED WITH INITIAL AND CONTINUOUS TRUST IN AUTONOMOUS SYSTEMS: A LITERATURE REVIEW

Maria Pena,¹ Jared Carrillo,² Nonna Milyavskaya,³ and Thomas Chan,³ 1. *California State University Northridge, Pacoima, California, United States*, 2. *California State University Northridge, Van Nuys, California, United States*, 3. *California State University Northridge, Northridge, California, United States*

Many autonomous systems are being developed to assist older adults to age in place. However, there is little research related to the human factors associated with why older adults may initially and continuously trust these autonomous systems. More research in this area on older adults and trust in autonomy is needed to facilitate the technologies better everyday use. The current study conducted a literature review on the prevalent human factors that enable people to trust their interactions with smart technologies (e.g., artificial intelligence, navigational structures). Articles were collected from various disciplines on concepts such as trust in autonomy, human-computer interactions and teamwork. Thematic analysis revealed two convergent areas that were associated with initial and continuous trust: human and technological characteristics. Human characteristics are defined by a person's ability to understand and use autonomous systems. Generally, people with higher competency and abilities with autonomous systems demonstrated the ease of use to carry out desired actions with smart technology. Technological characteristics are defined by the system's performance, explainability, and its intended purpose between trust. Essentially, people were less critical of autonomous systems that were perceived to be useful, transparent, and predictable. Overall, the autonomous system's ability to perform its intended purpose and the users knowledge and technical qualifications dominate the relationship between initial and continuous trust with autonomous systems. These are the prevalent factors that need to be considered for the creation of trusted autonomous technologies for older adults to help them age in the approaching more advanced technological world.

INTERACTION EFFECT OF SUBJECTIVE HEALTH AND ATTITUDE ABOUT AGING ON GERONTECHNOLOGY ACCEPTANCE

Hayoung Park,¹ Susanna Joo,² Kwang Joon Kim,³ Chang Oh Kim,³ Yun Mook Lim,¹ and Hey Jung Jun,¹

1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea*, 3. *Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

This study examined the interaction effect of subjective health and attitude about aging on gerontechnology acceptance among Korean older adults. The sample was 310 Korean older adults aged 65 and above without cognitive impairment who completed an online survey. The dependent variable was the attitude about gerontechnology, especially an exoskeleton robot for exercise. The independent variable was subjective health measured by the questions about self-reported health conditions. The moderating variable was the attitude about aging, which was measured by asking how much they feel less useful as they age. Covariates were age, gender, education level, employment status, income, and marital status. The results from the regression analyses using PROCESS macro and bootstrapping showed that the interaction effect of subjective health and attitude about aging is significant for gerontechnology acceptance; when older adults consider themselves less useful as they age, they tend to have positive attitudes about gerontechnology despite their subjective health. However, of those who consider that they are not less useful as they age, they tend to have positive attitudes about gerontechnology only when they consider themselves unhealthy. Thus, they tend to have negative attitudes about gerontechnology when they consider themselves healthy and useful. The findings imply that gerontechnology-based exercise programs or interventions could be welcomed by those who consider themselves unhealthy and think they are useless as they age. Also, the findings suggest that when applying an intervention program using gerontechnology, health status and self-assessment of aging should be considered in advance.

OLDER KOREANS' INFORMATION SUPPORT AND INTERNET USE: INTERNET SKILLS AND TECHNOLOGY ATTITUDES

Hye Soo Lee, *Oregon State University, Corvallis, Oregon, United States*

While older Koreans have growing access to Internet, they still lag in actual utilization. This study examined effects of different information support sources on Internet utilization and whether these were mediated by Internet skills and technology attitudes among older men and women. This study used secondary data from 2019 Digital Divide Survey conducted by National Information Society Agency of Korea. The sample consisted of 1,031 Korean Internet users aged 60+, including 495 men and 536 women. Support sources included personal and professional. Skills were measured by ability to use specific features of mobile devices such as smartphones (seven items), while utilization was measured by the use of mobile devices for specific reasons (25 items). Serial mediation analyses using both skills and attitudes were conducted separately according to gender and support sources, covarying for demographics and health. In general, information support was positively associated with utilization. For men, personal informational support was mediated by technology attitudes only. For women, professional informational support was mediated by both Internet skills and

technology attitudes, but the serial indirect effect was not significant for this model. The other two models showed significant serial mediation effects through Internet skills and technology attitudes, in this order. Only women had significant direct associations between information support and Internet utilization. Regardless of the source, informational support is positively associated with older Koreans' Internet utilization. Professional support for men and personal support for women may be most beneficial for greater Internet utilization.

PRIVACY AND USABILITY IN COVID ENROLLMENT APPS

Laura Calloway,¹ Lesa Huber,² and L. Jean Camp,¹ 1. *Indiana University, Bloomington, Indiana, United States*, 2. *School of Public Health, Indiana Univ, Bloomington, Indiana, United States*

Enrollment apps for COVID-19 vaccinations are meant to be privacy-enhancing, but poor design puts privacy at risk. We report on a qualitative exploration of the experiences of older adults attempting to register for vaccination. We engaged in a think-aloud protocol with six participants over age 65 over Zoom as they used the New York state vaccination portal. Authentication requirements were: Medicare ID, DOB, address, and phone (optional). For this cohort, Social Security numbers were the default Medicare ID. We found that a privacy-enhanced authentication option exists, but efforts to use privacy-preserving enrollment were confounded by security-enhancing timeouts. Choosing to use the time-consuming privacy-preserving authentication increased the risk that available vaccines were taken. As a result, older adults reliant on volunteers to enroll revealed sensitive information and risked identity theft. A design that was meant to be privacy-enhancing by offering multiple avenues for authentication and ensuring logout via timeouts created a system where the more secure option was not effectively available due to a competing security mechanism. This was exacerbated by a counter counting down the number of vaccine sites available, similar to a well-known stress condition used to create cognitive load in laboratory experiments. All six participants used privacy-sensitive information to enroll; provided adequate information for identity theft; and all six encountered stop points. The countdown of available vaccination sites, the time required for insurance validation as an alternative to Medicare ID, and logging off after inactivity to prevent session theft each are good practices; but fail together.

SOCIAL PARTICIPATION AND ATTITUDE TOWARDS GERONTECHNOLOGY: THE MODERATING ROLE OF FRAILTY STATUS

Ka Yeon Lee,¹ Sun Ah Lee,² Susanna Joo,³ YoonMyung Kim,¹ Yun Mook Lim,¹ and Hey Jung Jun,¹ 1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *The Pennsylvania State University, University Park, Pennsylvania, United States*, 3. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea*

The purpose of this study was to examine whether frailty status moderates the association between social participation and attitude towards using gerontechnology. The sample was Korean older adults without cognitive impairment

(N = 310, aged 66-90, 51% women) who completed an online survey. The attitude towards using gerontechnology was measured with two questions from the Senior Technology Acceptance Model (Chen & Chan, 2014), asking whether using technology is a good idea and whether they like the idea of using technology. Social participation was assessed by asking whether the participants engage in social or community activities on a scale of 1–10. Frailty status was determined based on the Korean Groningen Frailty Indicator (K-GFI). Covariates were age, gender, marital status, employment status, education level, and household income. Results from regression analyses showed significant interaction between frailty status and social participation on attitude towards using gerontechnology. Specifically, social participation was associated with positive attitude towards using gerontechnology among non-frail older adults. This association was not significant among frail older adults. Our findings suggest that the relationship between social participation and attitude towards using gerontechnology might differ by physical health status. Among older adults who are physically healthy and actively participate in social activities, the attitude towards using gerontechnology might be more positive due to greater exposure to new technology-related information. Future studies need to address alternative ways to enhance technology-friendliness among older adults with poor physical health.

TECHNOLOGY ANXIETY ON ATTITUDE TOWARDS TECHNOLOGY: THE MODERATING EFFECT OF AGE-FRIENDLY ENVIRONMENT

Do Kyung Yoon,¹ Seolah Lee,¹ DaeEun Kim,¹ Chang Oh Kim,² and Hey Jung Jun,¹ *1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The purpose of this study was to examine the moderating effect of an age-friendly environment on the relationship between technology anxiety and attitude towards technology among Korean older adults. We collected data by online surveys in February 2021, and the sample was 324 Korean older adults aged 65 and above. The dependent variable was the attitude towards technology, which meant the appraisal about using a wearable robot for exercise. The independent variable was technology anxiety, meaning an individual's apprehension of using a wearable robot. The moderating variable was age-friendly environment, which comprises domains of the physical environment, social environment, and municipal services. The higher the score is, the more age-friendly the environment was perceived. Control variables were age, sex, education, household income. The moderation effect was estimated by bootstrapping and PROCESS macro. Results showed that when older adults showed a higher level of technology anxiety, their attitude towards technology was less positive. Moreover, the moderation effect of an age-friendly environment was significant. Concretely, in the case of living in a less age-friendly environment, older adults with a higher level of technology anxiety were more likely to report a less positive attitude towards technology. However, the effect of technology anxiety on attitude towards technology was not significant among older adults living in a more age-friendly environment. It suggested that a practical intervention to

reduce the level of technology anxiety is in need in order to promote a positive attitude towards technology, especially for older adults living in a less age-friendly environment.

TECHNOLOGY USE, COMFORT, AND INTEREST: A COMPARISON BETWEEN CAREGIVER AND OLDER ADULT POPULATIONS

Sarah Hubner,¹ Akankshya Chataut,¹ Marcia Shade,² Ann Fruhling,¹ Natalie Manley,² Meaghan Fitzgerald Walls,³ and Julie Blaskewicz Boron,¹ *1. University of Nebraska Omaha, Omaha, Nebraska, United States, 2. University of Nebraska Medical Center, Omaha, Nebraska, United States, 3. University of Nebraska Omaha, University of Nebraska at Omaha, Nebraska, United States*

Remaining community-dwelling is a goal for most aging adults; however, this may necessitate assistance from caregivers. To reduce burden and improve adult autonomy, recent technological advancements have provided various supports. These advancements may improve quality of life (QOL) while also enhancing psychological/physical well-being for adults and caregivers. To investigate relationships between technology, QOL, and caregiver burden, needs assessments with focus groups were utilized. Four older adult focus groups (N=20) and three caregiver focus groups (N=12) were convened. Older adult participants, aged 64-83 years (M=73.1,SD=5.3), were 50% female and generally white (90%). Caregiver participants, aged 31-78 years (M=61.9,SD=12.6), were majority female (83%) and generally white (92%). Because of the ongoing COVID-19 pandemic, focus groups were conducted via Zoom video-conferencing. Thematic analyses revealed major themes of privacy, transportation, and interest in streamlined technologies. Throughout groups, privacy was consistently described; participants were either 1) apathetic, noting absence of privacy or 2) hyper-vigilant about security, citing privacy as a major barrier to utilization. Transportation, specifically self-driving/enhanced vehicles, emerged as a focus for future technologies as a means to reduce care burden and improve personal autonomy/QOL. In general, participants noted that major barriers to technology use included complexity and cost; persons expressed interest in simpler/cheaper devices. This study indicates varied interest in technology while exposing barriers to use. Additionally, the methodology demonstrates the utility of technology (e.g., Zoom) in accessing vulnerable and/or isolated populations. Overall, understanding barriers to technology use and adoption informs upcoming developments and may improve accessibility and usefulness in future systems/devices.

THE ROLE OF AGE-FRIENDLY ENVIRONMENT BETWEEN COGNITIVE ABILITY AND ATTITUDE TOWARDS GERONTECHNOLOGY

Inhye Jung, Miseon Kang, Si Young Song, Yun Mook Lim, and Hey Jung Jun, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

This study examined the impact of the age-friendly environment on the association between cognitive ability and the attitude towards gerontechnology. The participants were 277 Korean young-old age 65 through 74. The data were collected by an online survey conducted in February 2021. The dependent variable was the attitude towards gerontechnology

sum of perceived usefulness, perceived ease of use, and perceived adaptability (Heerink et al., 2010; Xu et al., 2015). The independent variable was the cognitive ability of participants to report on their own. The moderating variable was the age-friendly environment sum of physical, service-side, and cultural conditions. Multiple regression analysis was conducted to determine the relation between cognitive ability and the attitude towards gerontechnology. The moderating effect was then analyzed using PROCESS macro and bootstrapping. Results show that cognitive ability has a positive effect on the attitude towards gerontechnology, and the age-friendly environment has softened its effectiveness. When participants were living in a more age-friendly environment, their attitude toward gerontechnology was less affected by their cognitive ability. However, when age-friendly environmental condition scores above 62 (out of 75), the environmental aspect did not affect the association between cognitive ability and attitudes to gerontechnology. This study suggests that the age-friendly environment can narrow the disparity of the attitude towards gerontechnology depending on the cognitive capability levels under certain conditions. Regarding the attitude towards technology may affect the actual use, the possibility of environmental help is meaningful.

TRUST WITH AUTONOMOUS INTELLIGENCE SYSTEMS TO PROMOTE ADOPTION IN ASSISTIVE TECHNOLOGIES: A LITERATURE REVIEW

Jared Carrillo,¹ Maria Pena,² Nonna Milyavskaya,³ and Thomas Chan,³ 1. *California State University Northridge, Van Nuys, California, United States*, 2. *California State University Northridge, Pacoima, California, United States*, 3. *California State University Northridge, Northridge, California, United States*

While advancements in machine learning are increasing rapidly, very little progress has been made in its mass adoption despite its benefits in assistive technologies for older adults. By examining how users interact with smart technologies, characteristics of trust can be identified and enhanced to increase adoption of the next generation of assistive systems. The current study conducted a literature review to understand better how trust with autonomous systems is formed and maintained. Twenty-two pertinent articles were identified in which three themes emerged. First, people tend to forgive human errors more than errors made by machines -- meaning mistrust is exaggerated when systems make mistakes. Second, the development of trust depends on how the system solves the tasks it is assigned, for instance if a user does not believe the system acted in an "ethical way," distrust may form and the continuation of adoption is decreased. Lastly, trust depends on the situation and the risk/reward associated with using the system, for example the trust needed to board an autonomous plane differs from that for a simple grammar correction. Taken together, the black box ideology of autonomous systems may be an issue that prevents trust in them to be formed and maintained. Promising future directions are to create machine language translators that improve transparency of autonomous system behaviors (i.e., explainability). Even if assistive technologies are created to aid older adults -- the lack of focus on understanding the factors that foster trust may dampen their actual use.

USING SMART SPEAKERS IN LOW-INCOME SENIOR HOUSING TO ENHANCE THE AGING IN PLACE EXPERIENCE: STAKEHOLDER VIEWS

Jane Chung,¹ Jodi Winship,² Katherine Falls,² Pamela Parsons,² and Michael Bleich,² 1. *Virginia Commonwealth University, Virginia, United States*, 2. *Virginia Commonwealth University, Richmond, Virginia, United States*

Smart speakers provide a platform that can integrate smart home technology and/or safety devices within the home to enhance quality of life and independent living for older adults. However, few attempts to utilize this technology specifically within low-income senior housing (LISH) residents have been documented. Our purpose was to explore different stakeholder perceptions about the use of smart speakers to support aging in place in older adults living alone in LISH. Smart speakers were deployed in individual LISH apartments, equipped with a voice technology-based aging in place solution for the facility. A qualitative analysis of semi-structured interviews using a constant comparative approach for emerging themes was conducted (n=10: older adult users, n=2: housing staff, n=2: voice technology developers). The three participant groups showed diverging perceptions in terms of benefits, uses, and stakeholder interests. Older adults found smart speakers useful in four main areas: assistance with daily tasks, feeling connected, safety measures, and emotional wellbeing. The two other groups showed a broader interest in the use of the smart speaker device, such as residential management tools and communication channels in addition to its potential use as safety and wellness tools. Older adults experienced significant difficulty setting up desired functions or finding instructions, which restricted utilization of the technology to a limited set of tasks. All stakeholder groups addressed a need for formal training or personalized tech support for older adult users. Findings indicate the importance of developing deployment strategies tailored to the needs and characteristics of the target user group.

VOICES OF CAREGIVERS: KEY DEMANDS TOWARDS AI-DRIVEN HOME MONITORING IN COMMUNITY-BASED DEMENTIA CARE

Christian Wrede,¹ Annemarie Braakman-Jansen,² and Lisette van Gemert-Pijnen,² 1. *University of Twente, Dept. of Psychology, Health & Technology, Enschede, Overijssel, Netherlands*, 2. *University of Twente, Enschede, Overijssel, Netherlands*

While most people with dementia prefer to live at home for as long as possible, this also puts more pressure on both their informal and formal care network. To provide support in home-based dementia care, there is growing interest in technology that allows caregivers to remotely monitor health and safety of people with dementia. Novel generations of these technologies are using non-wearable, pervasive sensors coupled with algorithms to continuously collect and model meaningful in-home information. However, while these self-learning monitoring systems develop rapidly, their target users' views and demands are still insufficiently mapped out. To identify possible barriers to acceptance and ways to overcome these, we conducted a scenario-based study, including semi-structured interviews with informal caregivers (n=19)

and focus groups with home care professionals (n=16) of community-dwelling people with dementia. Inductive qualitative content analysis revealed that both groups of caregivers were concerned about the informational privacy of their care recipient with dementia, information overload, and ethical issues related to dehumanizing care. Identified demands mainly centered around how to overcome these barriers. We identified several demands related to specific functionalities, user experience factors, services surrounding the technology, and integration into the existing work context. Most notably, caregivers highlighted the importance of introducing AI-driven in-home monitoring technologies in a way it prevents them from feeling undervalued. In conclusion, our findings can help to inform the development of more acceptable and unobtrusive in-home monitoring technologies to support home-based dementia care.

WHAT FACTORS ARE ASSOCIATED WITH FACILITATING CONDITIONS TO USE GERONTECHNOLOGY?

Hayoung Park,¹ Susanna Joo,² DaeEun Kim,¹ YoonMyung Kim,¹ and Hey Jung Jun,¹ 1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea*

The purpose of this study is to explore relevant factors associated with facilitating conditions to use gerontechnology among Korean older adults. The sample was 310 Korean older adults aged 65 and above without cognitive impairment who participated in an online survey. The facilitating conditions to use gerontechnology were measured by the sum of five questions about basic knowledge, available help, financial resources, accessibility, and social influences of using gerontechnology from the Senior Technology Acceptance Model (STAM). Possible relevant factors comprised socio-demographic characteristics, physical and mental health, environmental factors, and social relationships. The results from the linear regression analyses showed that employment status, household income, cognitive function, social activity participation, and support from friends or neighbors were significantly associated with facilitating conditions to use gerontechnology. Older adults who are employed, have higher household income, have better cognitive functions, participate more in social activities, and receive higher levels of support from friends or neighbors tend to be in more facilitating conditions to use gerontechnology. The findings from this study imply the necessity of facilitating conditions to use gerontechnology as social policies for older adults who are unemployed, have lower household income, have worse cognitive functions, and have fewer social resources. This study is meaningful in that it has empirically explored various factors related to facilitating conditions to use gerontechnology for older adults based on the STAM. Future studies are needed to explore significant factors associated with facilitating conditions to use gerontechnology via various contexts.

WHO MATTERS FOR THE SUBJECTIVE PERCEPTIONS TOWARD GERONTECHNOLOGY?

Susanna Joo,¹ Seong Hee Kim,² Changmin Lee,³ Chang Oh Kim,⁴ Yun Mook Lim,³ and Hey Jung Jun,³ 1. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi,*

Republic of Korea, 2. *Sungkyunkwan University, Seoul, Republic of Korea*, 3. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 4. *Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The present study aims to investigate how personal relationship satisfaction moderate the associations between types of social support providers and the subjective perceptions toward gerontechnology among Korean older adults. Data were collected by an online survey in February 2021. The sample was 256 older Koreans who have a partner and children (N=109 older adults with low personal relationship satisfaction, N=147 older adults with high personal relationship satisfaction, Age: 66-88, M=69.91, SD=4.19). The dependent variables for the subjective perceptions toward gerontechnology were attitude toward using gerontechnology and anxiety for gerontechnology. Independent variables were four types of social support providers (spouse, children, siblings/relatives, and friends/neighbor). Personal relationship satisfaction was a binary moderator, dividing the sample into low and high personal relationship satisfaction groups. We applied multigroup structural equation modeling. The results showed associations between social support providers and subjective perceptions toward gerontechnology differed by the quality of personal relationships. In detail, receiving support from spouses was associated with the lower level of anxiety of using gerontechnology among older adults in the low personal relationship satisfaction group. Moreover, receiving support from spouses was associated with a higher level of attitude toward using gerontechnology in the high personal relationship group. Receiving social support from other providers were not significant in both groups. The findings imply that the partner living with was salience for positive perception toward gerontechnology. Furthermore, support from spouses may differently work on the subjective perception toward gerontechnology by the quality of personal relationships.

Session 9085 (Poster)

Biology of Aging

AGE-RELATED PHENOTYPES LINKED TO ABERRANT EXPRESSION AND LOCALIZATION OF A TELOMERIC PROTEIN

Amanda Stock,¹ Kun Wang,¹ Chengyu Liu,² Ross McDevitt,¹ Chongkui Sun,¹ Yi Gong,¹ and Yie Liu,¹ 1. *National Institute on Aging, Baltimore, Maryland, United States*, 2. *National Heart, Lung, and Blood Institute, Bethesda, Maryland, United States*

Telomere attrition is associated with telomere biology disorders and age-related diseases. In telomere biology disorders, telomere uncapping induces a DNA damage response that evokes cell death or senescence. However, a causal mechanism for telomere attrition in age-related diseases remains elusive. Telomere capping and integrity are maintained by shelterin, a six-protein complex. Rap1 is the only shelterin member that is not required for telomere capping and is expressed at non-telomeric genomic and cytosolic regions. The objective of this study was to determine aberrant phenotypes

attributed to non-telomeric Rap1. To test this, we generated a Rap1 mutant knock-in (KI) mouse model using CRISPR/Cas9 editing, in which Rap1 at telomeres is prevented, leaving only non-telomeric Rap1. Cell fractionation/western blotting of primary fibroblasts from Rap1 KI mice demonstrated decreased Rap1 expression and Rap1 re-localization off telomeres, with an altered cellular distribution. This same difference in Rap1 is also observed in human cells with telomere erosion, indicating that aberrant Rap1 in our model may recapitulate Rap1 in aging and human telomere biology disorders. Compared to wild-type control mice, Rap1 KI mice exhibited increased body weight, altered cytokine levels, behavioral deficits, and decreased lifespan. In conclusion, our results reveal a novel mechanism by which telomere shortening may contribute to age-related pathologies by disrupting Rap1 expression and cell localization.

APOLIPOPROTEIN E IMPAIRS AGED BONE FRACTURE HEALING

Abhinav Balu,¹ Rong Huang,¹ Kristin Molitoris,¹ and Gurpreet Baht,² 1. *Duke Molecular Physiology Institute, Durham, North Carolina, United States*, 2. *Duke University, Durham, North Carolina, United States*

Bone fracture healing and osteoblast differentiation are impaired with advanced age. Using a combination of parabiosis and proteomic models, we identified apolipoprotein E (ApoE) to be an aging factor in bone regeneration. Circulating levels of ApoE increased with age in patients and in mice. ApoE impaired bone fracture healing by decreasing bone deposition in the fracture callus which subsequently decreased the mechanical strength of healed tissue. Osteoblasts serve as the sole bone forming cells within the body. In tissue culture models, ApoE treatment decreased osteoblast differentiation and activity which led to decreased matrix formation and mineralization. This inhibition of osteoblast differentiation relied on down-regulation of the Wnt/ β -catenin pathway. In mouse models, aged bone repair was rejuvenated when we lowered circulating ApoE levels using a hepatotropic AAV-siRNA model – serving as a proof of concept that ApoE can be targeted to improve bone repair in an older population. While promising, knockdown of circulating ApoE in such a fashion is likely not translatable to patient care. Thus, current work in our laboratory is focused on developing treatment strategies that temporally decrease circulating ApoE levels and consequently improve bone healing after acute injury and/or surgical orthopedic procedure in the geriatric population.

BDNF SNP C270T MODIFIES THE ASSOCIATION BETWEEN HISTORY OF HEAD INJURY AND COGNITIVE STATUS IN OLDER ADULTS

Mikaela Drewel,¹ Hector Gonzalez,¹ Gail Rattinger,² Joshua Matyi,¹ Alexandra Hammond,¹ Kaitlyn Kauzor,¹ Mona Buhusi,¹ and JoAnn Tschanz,¹ 1. *Utah State University, Logan, Utah, United States*, 2. *Binghamton University, Binghamton University, New York, United States*

Brain derived neurotrophic factor (BDNF), is a neurotrophin involved in neurogenesis and neuroplasticity. Several BDNF genes have been associated with cognitive function. Studies suggest head injury (HI) alters BDNF levels, and activities enhancing BDNF signaling promote

better cognitive outcomes. We investigated the relationship between HI and BDNF single-nucleotide polymorphisms (SNPs) in predicting cognitive performance in a population-based sample of older adults. 4165 participants (56.7% female), dementia-free at baseline, were assessed triennially [follow-up years: mean (SD) = 5.85 (4.20), median = 7.33, maximum = 11.39]. Mean (SD) age was 75.36 (6.84). Cognition was assessed using the Modified Mini-Mental State Exam (3MS) and HI history from self-report. We examined interactions between BDNF SNPs [rs56164415 (BDNF C270T), rs6265 (Val66Met), rs2289656 (BDNF receptor trkB), and rs2072446 (NGF/BDNF receptor p75)] and history of HI (none, one, or multiple) in predicting cognitive decline. Covariates included age, education, sex, and apolipoprotein (APOE) E4 allele presence. Linear mixed-effect models indicated BDNF C270T significantly modified the association between HI and cognitive status ($p < .006$). Specifically, minor T allele carriers with single or multiple HI scored on average 2.08 and 3.21 points lower on the 3MS, respectively, than non-T carriers with no HI. Unexpectedly, there was a trend for APOE4*HI ($p = .078$) in that APOE E4 carriers with multiple HI scored higher than those lacking APOE E4 and HI. In this population-based sample, rs56164415 predicted cognitive outcomes that varied by history of HI. Factors influencing BDNF signaling may provide a potential avenue for intervention in recovery from HI.

BIOLOGICAL AGING, MORTALITY, AND ALZHEIMER'S DISEASE RELATED BIOMARKERS FROM MIDLIFE TO OLD AGE

Carol Franz, Erik Buchholz, Amy Yongmei Qin, Xin Tu, and William Kremen, *University of California San Diego, La Jolla, California, United States*

People age at different rates and in different biological systems that may differentially contribute to accelerated decline. Better understanding of biological aging may contribute to identification of better targets for intervention. In 1005 VETSA participants we created 3 indicators of biological age: physiological age (PA), frailty, and brain age. PA included hemoglobin, glucose, lipids, height, weight, waist, systolic and diastolic blood pressure, and age. PA was calculated using the Klemera and Doubal (2006) method. The frailty index summed 37 health deficits (Jiang et al. 2017). A machine learning algorithm was used to estimate brain age across cortical and subcortical regions (Liem et al, 2017); predicted brain age subtracted from chronological age comprised the predicted brain age difference score (PBAD). Frailty and PBAD were calculated at waves 1, 2 and 3 when participants were average age 56, 62, and 68, respectively. PA markers were only available at waves 2 and 3. Outcome measures included mortality by wave 3 and scores on AD-related plasma biomarkers—Neurofilament light (NFL), Tau, and AB40 and AB42 at wave 3. Frailty at wave 1 and 2 predicted mortality. Frailty at wave 1 was significantly associated with wave 3 NFL, AB42 and AB40. Wave 2 & 3 frailty was associated with all biomarkers. Neither PA nor PBAD predicted biomarkers or mortality. The results are striking given the relatively young age of the sample. Even as early as one's 50s, frailty in a community-dwelling sample predicted accelerated decline and mortality when the outcome age was only 66-73.

CAN WE SIMPLIFY AGING?

Svetlana Ukraintseva, and Anatoliy Yashin, *Duke University, Durham, North Carolina, United States*

Aging is indeed a complex process, but can it be simplified, so we could efficiently prioritize candidate anti-aging interventions and select those with largest impacts on key negative consequence of the aging, i.e., on increases in mortality risk and comorbidities with age? Here we argue that human aging and its negative consequences for health and lifespan are essentially driven by the interplay among three processes: (i) depletion of limited body reserves (e.g., of stem, immune, neural, muscle cells); (ii) inherent deficiency of cell/tissue repair mechanisms, which leads to accumulation of damage, allostatic load, and systems dysregulation; and (iii) general slowdown of physiological processes in the body (such as metabolism, proliferation and information processing) with age that results in slower responses to stressors and delayed recovery after damage (i.e., decline in resilience), which in turn contributes to increase in vulnerability to death with age. We show that the interplay among these processes can have ambivalent effects on health and longevity that should be taken into account to develop optimal anti-aging and pro-longevity strategies. In order to be efficient on the long-term, the anti-aging interventions may need to target the different causes of aging (reserve depletion, damage accumulation, and slowdown) simultaneously, to avoid undesirable trade-offs.

DEMONSTRATION OF AGE-RELATED INCREASE IN BLOOD-BRAIN BARRIER PERMEABILITY BY LONGITUDINAL INTRAVITAL MICROSCOPY

Adam Nyul Toth,¹ Stefano Tarantini,¹ Jordan DeFavero,¹ Feng Yan,² Priya Balasubramanian,¹ Qinggong Tang,² Anna Csiszar,¹ and Zoltan Ungvari,¹ *1. University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, United States, 2. University of Oklahoma, Norman, Oklahoma, United States*

Age-related blood-brain barrier disruption and cerebrovascular rarefaction contribute importantly to the pathogenesis of both vascular cognitive impairment and dementia (VCID) and Alzheimer's disease (AD). Recent advances in geroscience research enable development of novel interventions to reverse age-related alterations of the cerebral microcirculation for prevention of VCID and AD. To facilitate this research there is an urgent need for sensitive and easy-to-adapt imaging methods, which enable longitudinal assessment of changes in BBB permeability and brain capillarization in aged mice, that could be used in vivo to evaluate treatment efficiency. To enable longitudinal assessment of changes in BBB permeability in aged mice equipped with a chronic cranial window, we adapted and optimized two different intravital two-photon imaging approaches. By assessing relative fluorescence changes over the baseline within a volume of brain tissue, after qualitative image subtraction of the brain microvasculature, we confirmed that in 24 month old C57BL/6J mice cumulative permeability of the microvessels to fluorescent tracers of different molecular weights (0.3 kDa to 40 kDa) is significantly increased as compared to that of 5 month old mice. Real-time recording of vessel cross-sections showed that apparent solute permeability of single microvessels is significantly increased in aged mice vs. young mice. Cortical capillary density, assessed

both by intravital two-photon microscopy and optical coherence tomography (OCT) was also decreased in aged mice vs. young mice. The presented methods have been optimized for longitudinal (over the period of 36 weeks) in vivo assessment of cerebrovascular health in preclinical geroscience research.

DIFFERENTIALLY METHYLATED GENES IN MUSCLE ASSOCIATED WITH GAIT SPEED IN A NON-HUMAN PRIMATE MODEL OF AGING

Ellen Quillen, Brett Frye, Bethany Wildeman, Maggie Stainback, Thomas Register, and Carol Shively, *Wake Forest School of Medicine, Winston Salem, North Carolina, United States*

Age-related changes in DNA methylation are potent regulators of gene expression and may in part explain the onset of disease and disability. Vervet monkeys are a well-described model of neurocognitive and physical aging. Like humans, gait speed declines with age in vervets, and variability in gait speed in older animals is associated with age-related musculoskeletal and cognitive decline. To identify methylation patterns linked to aging-related physical decline, we investigated differentially methylated loci in vastus lateralis biopsies of 29 female vervets aged 8-28 years (~25-90 years in humans). We evaluated 107,490 loci on the Illumina Infinium Methylation EPIC Human Array that aligned with high fidelity to the vervet genome using the R package minfi and fit generalized linear mixed models to account for underlying genetic relatedness. We found 13 CpG methylation sites associated with 12 genes (CALCR, EBF4, GDNF, GMCL1, HAND1, HOXC10, IRX2, LBX2, MPPED2, SHISA6, SOX2, and WNT2) significantly differentially methylated with gait speed. Increased methylation was negatively associated with gait speed for all loci except GMCL1, reflecting the pattern of global hypermethylation of skeletal muscle tissue with age. Several of the associated genes are involved in development and differentiation including HOXC10 and LBX2, which regulates myoblast migration. CACNG8 regulates voltage-dependent calcium gated channels, and GDNF promotes motor neuron innervation of skeletal muscle. Most associations with muscle phenotypes are novel, but several have been linked to age-related bone diseases. We are currently evaluating the relationships of these differentially methylated loci with muscle mRNA expression and protein abundance.

EFFECT OF COMBINED STRESSORS ON C. ELEGANS LIFESPAN

Bradford Hull,¹ and George Sutphin,² *1. University of Arizona, Arizona, United States, 2. The University of Arizona, Tucson, Arizona, United States*

Cellular stress is a fundamental component of age-associated disease. Cells experience many forms of stress (oxidative, heavy metal, etc.), and as we age the burden of stress and resulting damage increases while our cells' ability to deal with the consequences becomes diminished due to dysregulation of cellular stress response pathways. By understanding how cells respond to stress we aim to slow age-associated deterioration and develop treatment targets for age-associated disease. The majority of past work has focused on understanding responses to individual stressors. In contrast, how pathology and stress responses differ in the

presence of multiple stressors is relatively unknown; we investigate that here. We cultured worms on agar plates with different combinations of arsenic, copper, and DTT (which create oxidative/proteotoxic, heavy metal, and endoplasmic reticulum (ER) stress, respectively) at doses that result in 20% lifespan reduction individually and measured the effect on lifespan. We found that arsenic/copper and arsenic/DTT combinations created additive lifespan reductions while the copper/DTT combination created an antagonistic lifespan reduction when compared to controls ($p < 0.05$). This antagonistic toxicity suggests an interaction either between the mechanisms of toxicity or the cellular response to copper and DTT. We are now evaluating the impact of copper and DTT individually and in combination on unfolded protein and heavy metal response pathways to understand the underlying mechanism of the interaction. Additionally, we are continuing to screen stressors to identify combinations that cause non-additive (synergistic or antagonistic) toxicity to build a comprehensive model of the genetic stress response network in *C. elegans*.

EFFECTS OF FOXO3 ON MARKERS OF AGING IN BLOOD : AN OKINAWAN LONGEVITY COHORT STUDY

Richard Allsopp,¹ D. Craig Willcox,² Trevor Torigoe,³ Mariana Gerschenson,³ Michi Shimabukuro,⁴ Randi Chen,¹ Tim Donlon,³ and Bradley Willcox,⁵ 1. *Kuakini Medical Center, Honolulu, Hawaii, United States*, 2. *okinawa International university, International university of Okinawa, Okinawa, Japan*, 3. *JABSOM, Honolulu, Hawaii, United States*, 4. *Fukushima University, Fukushima Medical University, Okinawa, Japan*, 5. *Kuakini Medical Center, Kuakini Medical Center/Honolulu, Hawaii, United States*

FOXO3 is among only a few genes that demonstrate a consistently reproducible genetic association with human longevity. We previously demonstrated, in a cross-sectional study of Okinawan Japanese, that the principal longevity variant of FOXO3 (rs 2802292 “G allele”) protects against age-associated attrition of telomere length. We now expand upon this initial observation in a more detailed cross-sectional analysis of the effect of FOXO3 on telomerase activity, FOXO3 expression and inflammatory cytokine levels in both men and women. In agreement with our initial study, we found the FOXO3 longevity variant conferred significant protection against telomere shortening to roughly the same degree in elderly (ages 55 and older) men and women. Carriers of the G - allele also had slightly higher levels of blood telomerase activity in young (ages 20 – 54) and elderly participants ($P \leq 0.1$). The expression (mRNA) of FOXO3 increased steadily with age in young and old G – allele carriers (borderline $P \leq 0.08$), in contrast to a lack of association with age in non-carriers. The FOXO3 G - allele was also observed to significantly impact levels of both interleukin 6 (IL 6) and IL10, but in a sex dependent manner ($P < 0.05$). These sex-specific effects may point to different mechanisms by which FOXO3 exerts its effect on longevity in men and women.

EPIGENETIC SIGNATURE OF CHILDHOOD ADVERSITY IN OLDER ADULTS

Eric Klopach, and Eileen Crimmins, *University of Southern California, Los Angeles, California, United States*

Past research has shown that childhood adversity (CA) affects the health of older adults; however, the biological mechanisms underlying this association are unclear. Though past research has implicated DNA methylation (DNAm), studies utilizing representative data from older adults and reliable DNAm measures are needed to answer key questions about how stable DNAm changes associated with CA are in later life. Methylation risk scores (MRSs) are an emerging tool that can be used as biomarkers of exposure and as a dimension reduction approach for mediation analyses. This study clarifies the association between CA and later life health by generating MRSs for childhood adversity based on an epigenome wide association study conducted in an independent sample and validating that measure in a nationally representative sample of older adults living in the US from the Health and Retirement Study (HRS), including 2016 methylation data from the HRS Innovative Subsample of the Venous Blood Study. For these 4,018 respondents, DNAm was assessed in whole blood using the Illumina Infinium Human Methylation EPIC BeadChip microarray. Results indicate that retrospective report of childhood SES is significantly associated with an MRS for CA after controlling for demographic factors (viz., race and ethnicity, age, gender, smoking status, and BMI), suggesting that DNAm signal from CA persists across the life course into older adulthood. This study helps clarify the biological processes underlying the association between CA and adult health.

EPIGENETIC TRAJECTORIES OF AGING AND REPROGRAMMING

Peter Niimi,¹ Morgan Levine,¹ and Margarita Meer,² 1. *Yale University, New Haven, Connecticut, United States*, 2. *Yale University, Yale University, Connecticut, United States*

The epigenetic landscape is remodeled with age, bringing about widespread consequences for cell function. With the revolutionary discoveries by Yamanaka and Takahashi, as well as those that built on this work, the transcription factors Oct4, Sox2, KLF4, and C-Myc (OSKM) can be expressed in a variety of cells, including fibroblasts, to make iPSCs. Once cells are reprogrammed, they show an erasure of epigenetic remodeling, suggesting an avenue to reverse aging. It has been recently shown that ectopic expression of three factors, OSK, can restore vision in mouse glaucoma model and reduces epigenetic age. It is not known the path epigenetic remodeling takes or whether all three factors, OSK, are required to remodel the epigenetic landscape. We hypothesize that during reprogramming, cells will reverse along a similar path they took during aging and eventually reverse along that path they took during differentiation. Alternatively, it may also be possible that cells take entirely new paths to reach a state of partial reprogramming or pluripotency. We used DNA methylation and RNA-seq as a multi-omics approach to map the trajectories cells make during aging, differentiation, and reprogramming. In human fibroblasts and hepatocytes, we tested the three-factor OSK mix, as well as pairwise factors OS, OK, and SK and individual Oct4, Sox2, and KLF4 for their effect on cell trajectories. This study provides a dynamic model for epigenetic changes in aging, differentiation, and reprogramming and highlights barriers and bottlenecks throughout the process.

EPIGENOME WIDE ASSOCIATIONS OF SMOKING BEHAVIOR IN THE HEALTH AND RETIREMENT STUDY

Jonah Fisher,¹ Colter Mitchell,² Helen Meier,¹ Eileen Crimmins,³ Bharat Thyagarajan,⁴ and Jessica Faul,²
 1. *University of Michigan, Ann Arbor, Michigan, United States*,
 2. *University of Michigan, University of Michigan, Michigan, United States*,
 3. *University of Southern California, Los Angeles, California, United States*,
 4. *University of Minnesota, Minneapolis, Minnesota, United States*

DNA methylation (DNAm) is an increasingly popular biomarker of health and aging outcomes. Smoking behaviors have a significant and well documented correlation with methylation signatures within the epigenome and are important confounding variables to account for in epigenome-wide association studies (EWAS). However, the common classification of individuals as ‘current’, ‘former’, and ‘never’ smokers may miss crucial DNAm patterns associated with other smoking behaviors such as duration, intensity, and frequency of cigarette smoking, resulting in an underestimation of the contribution of smoking behaviors to DNAm and potentially biasing EWAS results. We investigated associations between multiple smoking behavioral phenotypes (smoking pack years, smoking duration, smoking start age, and smoking end age) and single site DNAm using linear regressions adjusting for age, sex, race/ethnicity, education, and cell-type proportions in a subsample of individuals who participated in the HRS 2016 Venous Blood Study (N=1,775). DNAm was measured using the Infinium Methylation EPIC BeadChip. All 4 phenotypes had significant associations (FDR < 0.05) with many methylation sites (packyears=6859, smoking duration=6572, start age=11374, quit age=773). There was not much overlap in DNAm sites between the full set of models with only 6 overlapping between all 4. However, the phenotypes packyears and smoking duration showed large overlap (N=3782). Results suggest additional smoking phenotypes beyond current/former/never smoker classification should be included in EWAS analyses to appropriately account for the influence of smoking behaviors on DNAm.

GENOMIC ANALYSIS OF NAD+ SYNTHESIS PATHWAYS INVOLVED IN AGING AND CANCER

Jeremy Meyers,¹ Raul Castro-Portuguez,² Luis Espejo,³ and George Sutphin,² 1. *University of Arizona, Tucson, Arizona, United States*, 2. *The University of Arizona, Tucson, Arizona, United States*, 3. *UNIVERSITY OF ARIZONA, TUCSON, Arizona, United States*

Cancer cells have elevated energy demands to sustain continuous growth and other malignant processes and undergo extensive metabolic reprogramming to meet these demands. One element of this reprogramming in many cancer subtypes is elevated synthesis of nicotinamide adenine dinucleotide (NAD+), a critical co-enzyme that supports energy production through both glycolysis and the TCA cycle. The kynurenine metabolic pathway is the evolutionarily conserved means by which cells produce NAD+ de novo from tryptophan. NAD+ levels drop with age, a contributing factor to many forms of age-related disease. While interventions that increase NAD+ have been shown to extend lifespan, previous work from our lab demonstrates that

knockdown of several kynurenine pathway enzymes, thus decreasing de novo NAD+ production, results in increased longevity of *Caenorhabditis elegans* by 20-30%. To address this apparent contradiction, we propose that kynurenine pathway inhibition may produce metabolic feedback that results in upregulation of NAD+ recycling. Eukaryotic cells recycle NAD+ from nicotinamide (NAM) through one of two pathways: the Salvage pathway in mammalian cells and the Preiss-Handler pathway in *C. elegans* and related invertebrates species. We are using tools in *C. elegans* and human cell culture to examine the interaction between kynurenine/de novo NAD+ synthesis and NAD+ recycling through Salvage and Preiss-Handler. In particular, we are interested in how combining interventions between these pathways will influence activity throughout the NAD+ metabolic networks (measured via mass spectrometry), physiological phenotypes, and transcriptomic changes (via RNA sequence data) involved in aging and age-associated disease.

INSERTION OF THE PROTECTIVE APP A673T MUTATION BY CRISPR/CAS9 BASE EDITING OR PRIME EDITING.

Jacques Tremblay,¹ Antoine Guyon,² Joël Rousseau,¹ Guillaume Tremblay,¹ Francis-Gabriel Begin,¹ and Gabriel Lamothe,¹ 1. *Laval university, Québec, Québec, Canada*, 2. *Laval university, Québec, Québec, Canada*

There is currently no treatment for Alzheimer disease (AD). However, the Icelandic mutation in the APP gene (A673T) has been shown to confer a protection against the onset and development of AD (Jonsson et al. Nature 2012). This single nucleotide mutation in APP exon 16 reduces the cleavage of the APP protein by the beta-secretase by 40% thus preventing the development of AD even in persons more than 95 years old. Our research group has initially shown that the presence of the A673T mutation in an APP gene reduced the secretion of beta-amyloid peptides even if there is also a FAD mutation in the gene. This is the case for 14 different FAD mutations. We have used CRISPR/Cas9 base editing and PRIME editing technologies to insert the A673T mutation in the APP gene. We have compared several different cytidine base editor complexes to achieve the most effective and accurate genome modification possible in HEK293T cells and in SH-SY5Y neuroblastomas. The insertion of the A673T mutation in cells containing the London mutation reduced the secretion of beta-amyloid peptides. We are currently using lentiviral vectors to infect neurons from a mouse model and human neurons induced from fibroblasts of a patient with the London mutation. The insertion of the protective Icelandic mutation in the APP gene using these editing technologies opens a new potential therapeutic avenue not only for Familial Alzheimer’s diseases but also for sporadic Alzheimer’s disease.

LINKS OF SLEEP DURATION WITH BIOMARKERS OF ACCELERATED AGING: THE BALTIMORE LONGITUDINAL STUDY OF AGING

Emily Smail,¹ Brion Maher,² Ann Moore,³ Pei-Lun Kuo,⁴ Mark Wu,⁵ Dominique Low,⁶ Katie Stone,⁷ and Adam Spira,² 1. *University of Florida, Baltimore, Maryland, United States*, 2. *Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*,

3. *National Institute on Aging, Baltimore, Maryland, United States*, 4. *National Institute on Aging, National Institute on Aging, Maryland, United States*, 5. *Johns Hopkins University School of Medicine, Baltimore, Maryland, United States*, 6. *Stanford University School of Medicine, Stanford, California, United States*, 7. *University of California, Berkley, San Francisco, California, United States*

Sleep disorders and sleep deprivation have been linked to markers of biological aging, including methylation change and increases in white blood cell and neutrophil counts. However, little is known regarding the association of sleep duration with biological markers of aging. We investigated links of self-reported sleep duration with biological aging markers in 615 participants in the Baltimore Longitudinal Study of Aging (BLSA) aged ≥ 50 years (mean = 71.0 ± 11.2 , 49.6% women, 68.8% white) with data on self-reported sleep duration in hours (i.e., ≤ 6 (n=131), >6 to 7 (n=234), >7 (n=250)), demographics, and genetic and methylation data (mDNA). Our aging biomarker outcomes were four epigenetic clocks (Horvath, Hannum, PhenoAge, and GrimAge), mDNA-estimated PAI1, and estimated granulocyte count. After adjustment for age, sex, and race, compared to those sleeping ≤ 6 hours, those reporting >7 hours of sleep had faster biological aging according to Hannum age-acceleration, PhenoAge, GrimAge, mDNA-estimated PAI1, and granulocyte count. In addition, sleep duration interacted with age, such that compared to individuals reporting ≤ 6 hours of sleep, individuals reporting >6 to 7 hours showed lower GrimAge with increasing age, and with sex, such that males with longer sleep duration (>6 to 7 and >7 hours) showed a lower granulocyte count compared to females. Findings suggest that both short and long sleep duration are associated with and may contribute to accelerated aging. Prospective studies in larger samples are needed to examine whether changes in sleep duration precede changes in aging biomarkers.

LONGITUDINAL COURSE OF GDF15 LEVELS BEFORE ACUTE HOSPITALIZATION AND DEATH IN THE GENERAL POPULATION

Juliette Tavenier,¹ Ove Andersen,¹ Jan O. Nehlin,¹ and Janne Petersen,² 1. *Copenhagen University Hospital Hvidovre, Hvidovre, Hovedstaden, Denmark*, 2. *Copenhagen University Hospital Frederiksberg, Frederiksberg, Hovedstaden, Denmark*

Growth differentiation 15 (GDF15) is a potential novel biomarker of biological aging. To separate the effects of chronological age and birth cohort from biological age, longitudinal studies investigating associations of GDF15 levels with adverse health outcomes are needed. We investigated changes in GDF15 levels over 10 years in an age-stratified sample of the general population and their relation to the risk of acute hospitalization and death. Serum levels of GDF15 were measured three times in 5-year intervals in 2176 participants aged 30, 40, 50, or 60 years from the Danish population-based DAN-MONICA cohort. We assessed the association of single and repeated GDF15 measurements with the risk of non-traumatic acute hospitalizations. We tested whether changes in GDF15 levels over 10 years differed according to the frequency of hospitalizations within 2 years, or survival within 20 years, after the last GDF15 measurement. The change in GDF15 levels over time was

dependent on age and sex. Higher GDF15 levels and a greater increase in GDF15 levels were associated with an increased risk of acute hospitalization in adjusted Cox regression analyses. Participants with more frequent admissions within 2 years, and those who died within 20 years, after the last GDF15 measurement already had elevated GDF15 levels at baseline and experienced greater increases in GDF15 levels during the study. The change in GDF15 levels was associated with changes in C-reactive protein and biomarkers of kidney, liver, and cardiac function. Monitoring of GDF15 starting in middle-age could be valuable for the prediction of adverse health outcomes.

METABOLIC SYNDROME AND NEUROCOGNITIVE FUNCTION AMONG OLDER HISPANICS/LATINOS WITH HIV

Maria Marquine,¹ Lily Kamalyan,² David Yassai-Gonzalez,¹ Mariana Cherner,³ Ronald Ellis,⁴ Anya Umlauf,⁴ Dilip Jeste,¹ and Robert Heaton,⁴ 1. *University of California San Diego, La Jolla, California, United States*, 2. *San Diego State University/University of California San Diego Joint Doctoral Program in Clinical Psychology, San Diego, California, United States*, 3. *University of California San Diego, SAN DIEGO, California, United States*, 4. *University of California San Diego, San Diego, California, United States*

Neurocognitive impairment is prevalent among persons with HIV (PWH), particularly among Hispanics/Latinos/as/x (henceforth Hispanics). We examined disparities in HIV-associated neurocognitive function between older Hispanic and non-Hispanic White PWH, and the potential role of metabolic syndrome (MetS) in explaining these disparities. Participants included 116 community-dwelling PWH ages 50-75, who were enrolled in a cohort study in southern California (58 Hispanic [53% Spanish-speaking] and 58 age-comparable non-Hispanic White; Overall group: Age: M=57.9, SD=5.7; Education: M=13, SD=3.4; 83% male, 58% AIDS, 94% on antiretroviral therapy [ART], 4% detectable plasma RNA). A global neurocognition score was derived from T-Scores on a comprehensive neurocognitive battery, with separate demographic adjustments for English and Spanish-speakers. MetS was ascertained via standard criteria that considered central obesity, elevated triglycerides, low high-density lipoprotein cholesterol, and elevated fasting glucose, as well as current medical treatment for these conditions. Covariates examined included sociodemographic, psychiatric, substance use and HIV-disease characteristics. Hispanics had higher rates of MetS (56%) than non-Hispanic Whites (37%; $p < .05$). A stepwise regression model on global neurocognition including ethnicity and covariates that differed between ethnic groups, selected only Hispanic ethnicity as a significant predictor (B=-3.82, SE=1.27, $p < .01$). A comparable model also including MetS showed that both Hispanic ethnicity (B=-3.39, SE=1.31, $p = .01$) and MetS (B=-2.73, SE=1.31, $p = .04$), were significantly associated with worse global neurocognition. Findings indicate that MetS does not fully explain disparities in neurocognitive function between Hispanic and non-Hispanic White older PWH, but rather is an independent predictor of neurocognitive function along with Hispanic ethnicity.

METHODS USED IN 'ALDH2*2 ASSOCIATION WITH LONGEVITY AND REDUCED RISK OF COGNITIVE DECLINE IN JAPANESE-AMERICAN MEN'

Anubhav Nikunj Singh Sachan,¹ Steven Edland,¹ Julia Chosy,² Lenore Launer,³ Sudha Seshadri,⁴ and Lon White,² 1. *University of California San Diego, La Jolla, California, United States*, 2. *Pacific Health Research and Education Institute, Honolulu, Hawaii, United States*, 3. *National Institute on Aging, Bethesda, Maryland, United States*, 4. *UT Health San Antonio, San Antonio, Texas, United States*

ALDH2*2 is a loss of function mutation common in East Asian populations associated with facial flushing on exposure to alcohol and increased risk of certain cancers. Conversely, absence of the ALDH2*2 mutation is associated with increased risk of hypertension and cerebral microbleeds, and two recent studies report a higher frequency of ALDH2*2 alleles in nonagenarians compared to population control samples. We used survival analysis to investigate the association between ALDH2*2 and risk of cognitive impairment and death after controlling for midlife alcohol consumption and other covariates. Participants are 621 Japanese-American men (72 to 92) enrolled in the Honolulu Asia Aging Study (HAAS) and assessed for cognitive impairment for up to 20 years. Impairment was defined as crossing below a threshold score of 74 on the Cognitive Assessment Screening Instrument (CASI). Age at death was determined by Hawaii state death certificate. Ounces of ethyl alcohol consumed per month was assessed by structured interview (number, frequency, and type of beverage) conducted 25 years prior to baseline cognitive assessment. Persons heterozygous for the ALDH2*2 variant have reduced risk of cognitive impairment and reduced risk of death, compared to homozygote non-carriers. Covarying by alcohol exposure had no effect on observed associations. This study replicates previous findings associating ALDH2*2 with longevity, and provides evidence the protective effect extends to cognition. This poster details the statistical analysis carried out to obtain these results.

MTOR INHIBITION ALTERS MIRNA PROFILE IN CULTURED BONE MARROW MESENCHYMAL STEM CELLS

Lisa Stukenborg,¹ Manali Potnis,² and Christian Sell,¹ 1. *Drexel University College of Medicine, Philadelphia, Pennsylvania, United States*, 2. *Drexel University, PHILADELPHIA, Pennsylvania, United States*

Progressive decline in adult stem cell function is a feature of aged tissues and contributes to multiple age-related diseases. Of particular interest are bone marrow mesenchymal stem cells, also known as bone marrow stromal cells (BMSCs), which are multipotent, and have significant therapeutic potential for age-related disease. BMSCs isolated from older individuals show decreased differentiation and characteristics of cell senescence. We and others find that inhibition of the mTOR pathway prevents senescence and extends BMSC proliferation. We have examined miRNA profiles in rapamycin-treated BMSCs to identify miRNAs that may be needed to maintain "stemness" and facilitate differentiation in this population in undifferentiated cell populations. The analysis reveals a distinct miRNA profile induced by rapamycin associated with enhanced differentiation capacity.

PLASMA BIOMARKERS OF ANGIOGENESIS RELATED TO SMALL VESSEL BRAIN DISEASE IN SPRINT

Nicholas Pajewski,¹ Fanny Elahi,² Joachim Ix,³ Ilya Nasrallah,⁴ Jason Hinman,⁵ Lenore Launer,⁶ Jeff Williamson,¹ and Donna Wilcock,⁷ 1. *Wake Forest School of Medicine, Winston-Salem, North Carolina, United States*, 2. *University of California San Francisco, San Francisco, California, United States*, 3. *University of California San Diego, La Jolla, California, United States*, 4. *University of Pennsylvania, Philadelphia, Pennsylvania, United States*, 5. *David Geffen School of Medicine, University of California Los Angeles, Los Angeles, California, United States*, 6. *National Institute on Aging, Bethesda, Maryland, United States*, 7. *University of Kentucky, Lexington, Kentucky, United States*

Meta-analyses incorporating the Systolic Blood Pressure Intervention Trial (SPRINT) have shown a reduced incidence of dementia with blood pressure lowering. However, mechanistic explanations for this effect are lacking, apart from slowed progression of cerebral white matter lesions (WML). Here we examine possible biomarkers of angiogenesis related to small vessel brain disease including bFGF, FLT1, PLGF, TIE-2, VEGF, VEGF-C, and VEGF-D. The biomarkers were assayed in plasma at baseline and during follow-up (median follow-up = 3.8 years) in a subgroup of participants 60 to 89 years old from SPRINT (N=517). We modeled changes in each biomarker using robust linear mixed models accounting for treatment group, time since randomization, and kidney function. Participants were 69.8 ± 7.1 (standard deviation) years of age, 42.1% female, with a mean systolic blood pressure (SBP) of 138.2 ± 17.0 mm Hg. At baseline, none of the biomarkers were associated with WML lesion volume or total brain volumes adjusting for age (all $p > 0.05$), while FLT1, PLGF, and TIE-2 were negatively associated with frontal gray matter cerebral blood flow (partial correlations of -0.11, -0.10, and -0.12 respectively, all $p < 0.05$). For both intensive (target SBP < 120 mm Hg) and standard (target SBP < 140 mm Hg) blood pressure control, mean levels for the majority of biomarkers increased during follow-up, with the exceptions of TIE-2 (decreased over follow-up) and VEGF-D (no change). We did not observe significant between-group differences for the change in these plasma biomarkers of angiogenesis comparing intensive to standard blood pressure treatment.

SIRTUIN-1 ISOFORMS DIFFERENTIALLY REGULATE MITOCHONDRIAL FUNCTION

Xiaomin Zhang,¹ Fathima Ameer,² Jasmine Crane,² Gohar Azhar,² and Jeanne Wei,² 1. *University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*, 2. *UAMS, UAMS, Arkansas, United States*

Alternative splicing generates multiple distinct isoforms that increase transcriptome and proteome diversity. Alternatively spliced isoforms may lose part of the protein domain and have different intracellular localization as well as distinct functions. The main form of the SIRT1 (SIRT1v1) protein contains 11 exons. We have identified two new isoforms, SIRT1v2 (lost 2 exons), and SIRT1v3 (lost 3 exons), but their effect on mitochondrial gene expression has not been reported. To study the effect of the three SIRT1 isoforms on mitochondrial gene expression

and function, neuronal cells were transfected with SIRT1 isoforms v1, v2 or v3 plasmids, respectively. Gene expression was measured by quantitative reverse transcription PCR (RT-qPCR). Our data showed SIRT1 isoforms v1, v2 and v3 differentially regulated PCG-1alpha and PCG-1beta, which are the upstream regulators of mitochondrial structure and function. SIRT1v1 upregulated mitofusin-1 (MFN1), the mitochondrial dynamin-like GTPase (OPA1) gene, and the transcription factor A mitochondrial (TFAM) gene. In contrast, the SIRT1-v2 isoform repressed the MFN1, MFN2, and TFAM genes, while the SIRT1-v3 isoform repressed the MFN1 gene. In addition, the three SIRT1 isoforms differentially affected the mitochondrial respiratory complex I genes, including NDUFB1, NDUFS1, NDUFV1, NDUFV2. The data indicates that SIRT1 regulates mitochondrial biogenesis and function through a signaling pathway involving PCG-1alpha, PCG-1beta, mitofusin 1 and 2, OPA1, and TFAM genes. Taken together, alternative splicing generated three SIRT1 isoform proteins with diverse functions. Age-related changes in the alternative splicing events are likely to impact sirtuin-regulated cellular functions and signaling pathways in aging and senescence.

THE INTERPLAY BETWEEN STRESS RELATED GENES AND ITS ROLE IN HUMAN LONGEVITY: INSIGHTS FOR TRANSLATIONAL STUDIES

Anatoliy Yashin,¹ Deqing Wu,¹ Konstantin Arbeev,¹ Olivia Bagley,¹ Igor Akushevich,¹ Arseniy Yashkin,² Matt Duan,¹ and Svetlana Ukraintseva,¹ 1. *Duke University, Durham, North Carolina, United States*, 2. *Duke University, Morrisville, North Carolina, United States*

Human lifespan is a multifactorial trait resulted from complicated interplay among many genetic and environmental factors. Despite substantial progress in clarifying many aspects of lifespan variability the mechanism of its multifactorial regulation remains unclear. In this paper we investigate the role of genes from integrated stress response (ISR) pathway in such regulation. Experimental studies showed that persistent cellular stress may result in cellular senescence (for proliferating cells), or in apoptosis (for post-mitotic cells) which may affect health and lifespan in laboratory animals. These studies also showed which ISR genes are likely to interplay to produce joint effects on these traits. Note that in humans, the interplay between these genes does not necessarily influence these traits. This is because biological mechanisms regulating these traits in laboratory animals and humans may differ. This means that, when possible, the experimentally detected connections promising for human applications, should be verified using available human data before their testing in expensive clinical trials. In this paper we used HRS data to test connection between SNPs from the EIF2AK4 gene that senses cellular stress signals and the DDIT3 gene from the apoptosis regulation part of the ISR. We found genome wide significant associations between interacting SNPs from these genes and longevity. This result shows that available human data may be successfully used for making important steps in translation of experimental research findings towards their application in humans. Following this strategy may increase efficiency of clinical trials aiming to find appropriate medications to promote human health and longevity.

USING THRESHOLD REGRESSION AS AN APPROACH TO INCORPORATE INFORMATIVE MISSINGNESS IN LONG LIFE FAMILY STUDY DATA

Ilya Zhbannikov, Konstantin Arbeev, Olivia Bagley, Yuriy Loika, Alexander Kulminski, Svetlana Ukraintseva, Eric Stallard, and Anatoliy Yashin,, *Duke University, Durham, North Carolina, United States*,

Genetics of aging is important since aging is a major risk factor in most diseases. Variables describing physiological state and cognitive functioning that influence morbidity and mortality risks can serve as biomarkers of aging. They change with increasing age and the ways in which these variables change can also influence these risks. Missing data due to dropout or death create problems in longitudinal studies producing biased results especially if the gap between exams is relatively long, as is the case in the Long Life Family Study (LLFS). We applied the threshold regression model to LLFS data to investigate the vitality and its rate, which are conceptualized as latent variables characterizing health and longevity, and to cope with such a problem. We performed genome-wide association study by sex and age groups to discover genetic signals on these phenotypes. We found 11 variants from the DACT2 gene, p-values < 1E-6 and variants rs12151399 (p-value = 8.43E-8, intron variant, gene AGAP1, in females), rs27958 (p-value = 8.39E-8, intron variant, gene ARHGAP26, in males) showing associations with the vitality. Olfactory receptors showed significant enrichment among the group of males over 80 years for the rate of aging phenotype. Results showed that vitality and its rate differ among sex and age groups. This work is an important step toward understanding the processes of aging linking the vitality with individual genetics using data from deceased and living individuals.

Session 9090 (Poster)

Biology of Aging and Biobehavioral Health

A NOVEL PROBIOTICS THERAPY FOR AGING-RELATED LEAKY GUT AND INFLAMMATION

Shaohua Wang,¹ Bo Wang,² Sidharth Mishra,¹ Shalini Jain,¹ Jingzhong Ding,¹ Stephen Krtichevsky,³ Dalane Kitzman,¹ and Hariom Yadav,⁴ 1. *Wake Forest School of Medicine, Winston-Salem, North Carolina, United States*, 2. *NC A&T State University, Greensboro, North Carolina, United States*, 3. *Wake Forest School of Medicine, Wake Forest School of Medicine, North Carolina, United States*, 4. *Wake Forest Medical Center, Winston-Salem, North Carolina, United States*

Inflammaging characterized with increased low grade inflammation in older adults is common determinant of unhealthy aging; and is a major risk factor of morbidity and mortality in older adults. The precise origin of inflammation in older adults is not known, however, emerging evidence indicate that increased intestinal epithelial permeability (leaky gut) and abnormal (dysbiotic) gut microbiota could be one of the key source. However, no preventive and treatment therapies are available to reverse the leaky gut and microbiome dysbiosis in older adults. Here, we presented the evidence that a human-origin probiotics cocktail containing 5 Lactobacillus

and 5 *Enterococcus* strains isolated from healthy human infant gut can ameliorate aging-related metabolic, physical and cognitive dysfunctions in older mice. We show that the Feeding this probiotic cocktail prevented high-fat diet-induced (HFD-induced) abnormalities in glycose metabolism and physical functions in older mice and reduced microbiota dysbiosis, leaky gut, inflammation. Probiotic-modulated gut microbiota reduced leaky gut by increasing tight junctions on intestinal epithelia, which in turn reduced inflammation. Mechanistically, probiotics increased bile salt hydrolase activity in older microbiota, which in turn increased taurine deconjugation from bile acids to increase free taurine abundance in the gut. We further show that taurine stimulated tight junctions and suppressed gut leakiness. Further, taurine increased life span, reduced adiposity and leaky gut, and enhanced physical function in *Caenorhabditis elegans*. Whether this novel human origin probiotic therapy could prevent or treat aging-related leaky gut and inflammation in the elderly by reversing microbiome dysbiosis requires evaluation.

A PHASE 2B CLINICAL TRIAL ASSESSING LOMECEL-B INFUSION IN INDIVIDUALS WITH AGING FRAILTY: STUDY DESIGN AND RATIONALE

Kevin Ramdas,¹ Ben Hitchinson,² Lisa McClain-Moss,² Keyvan Yousefi,³ Liliana Diaz,² Jorge Ruiz,⁴ Joshua Hare,² and Anthony Oliva,² 1. *Longeveron, Inc., Miami, Florida, United States*, 2. *Longeveron, Inc, Miami, Florida, United States*, 3. *Longeveron Inc., Miami, Florida, United States*, 4. *VAMC, Miami, Florida, United States*

Frailty is a common and important geriatric syndrome characterized by age-associated declines in physiology and function across multiple organ systems, which lead to increased vulnerability to adverse health outcomes. A biological mechanism that underlies the decline in physical function associated with aging frailty is chronic inflammation. The MSCs in Lomecel-B have immuno-modulatory capacity and control inflammation and the cytokine production of lymphocytes. An individual's endogenous stem cell production decreases with age, this decrease likely contributes to reduced ability to regenerate and repair organs and tissues. Aging Frailty represents an exciting potential indication for cellular based therapies like Lomecel-B. This study is intended to evaluate the effects of Lomecel-B infusion compared to placebo on mobility and exercise tolerance, patient-reported physical function assessments and biomarkers for inflammation in individuals with Aging Frailty. This is a randomized, double-blind placebo-controlled, parallel multi-arm multicenter study enrolling adults aged 70-85 years identified as mildly or moderately frail per the CSHA Clinical Frailty Scale (CFS), with reduced six minute walk test (6MWT) and elevated Tumor Necrosis Factor- α (TNF- α), at screening. 150 subjects (30 per group) were randomized to receive a single peripheral intravenous infusion of 25, 50, 100, or 200 million doses, or placebo. Safety and efficacy assessments were conducted at 30, 90, 180, and 270 days after infusion. A follow up telephone call to subjects was placed at 365 days. We describe the design and rationale in detail of this 2b study assessing the effects of Lomecel-B on older adults with Aging Frailty.

CLAIMS-BASED NETWORK ANALYSIS OF DISEASE PROGRESSIONS IN COMPLEX AND NON-COMPLEX OLDER ADULTS

Peter Nicholas Onglao,¹ Ciara Janer,¹ Maria Eloisa Ventura,¹ and Lauren Bangerter,²

1. *OptumLabs, Minnetonka, Minnesota, United States*,
2. *OptumLabs, Eden Prairie, Minnesota, United States*

Older adults are the fastest growing subset of complex patients with high medical, behavioral, and social needs. Understanding differences in disease progression patterns between complex and non-complex older adults is critical for understanding disease risk and tailoring patient-centered interventions. We identified complex patients as those having frequent medical encounters and multiple chronic conditions within the first year of the study period and non-complex patients as the converse. This study compares the disease progression patterns of (a) complex and (b) non-complex older adults by creating disease progression networks (DPN) from claims data of 762,362 patients (mean age = 73) from 2016 to 2020. We characterized the network size and density between the complex patient DPN (C-DPN) and non-complex patient DPN (NC-DPN), and compared disease progression incidence, time-to-progression, and age- and gender-related risk. Results show that the C-DPN was denser and had a wider range of values for risk of progression compared to the NC-DPN. This implies more varied disease progression patterns occurring in the complex adults. We were also able to compare (median) time-to-progressions of diseases relative to each subpopulation and found variation in disease progression time. Furthermore, k-means clustering on the network allowed us to identify highly connected diseases involved in many disease pathways that are prevalent among older adults. (e.g., lipoprotein disorders, hypertension, major depressive disorder). Our results suggest that DPNs can be used to identify important conditions and time-points for tailoring care to the complex and non-complex older adults.

EFFECTS OF SMOKING CESSATION ON EPIGENETIC AGING

Brian Chen,¹ Weiye Wang,¹ Nichole Rigby,¹ Randal Olson,² and Steve Sabes,³ 1. *FOXO Technologies, Minneapolis, Minnesota, United States*, 2. *FOXO Technologies, FOXO Technologies, California, United States*, 3. *FOXO Technologies, FOXO Technologies, Minnesota, United States*

"Epigenetic clocks" have become widely used to assess individual rates of biological aging. However, experimental data are limited in humans to identify potential confounding factors that may influence one's rate of epigenetic aging and multiple health outcomes. We examined multiple epigenetic aging measures among regular smokers who quit smoking for two weeks. DNA methylation markers were assessed in both whole blood and saliva at multiple time points using a customized DNA methylation microarray. Generally, no changes in epigenetic aging rates were detected in the two week observation period with the exception of pronounced decreases over time in rate of Hannum's clock and Extrinsic Epigenetic Age Acceleration in blood DNA. In saliva DNA, decreases over time were detected in the rates of the GrimAge and DNAmPhenoAge clocks, but we saw an increase in the

rate of the Skin and Blood Clock. Additional experimental studies of other common exposures may be useful to better characterize factors that may affect the observed “rate” of epigenetic aging.

EXPLORING HEALTH IN THE UK BIOBANK: SOCIODEMOGRAPHIC, PSYCHOSOCIAL, LIFESTYLE AND ENVIRONMENTAL FACTORS

A greater understanding of factors associated with favourable health may help increase longevity and healthy life expectancy. We examined sociodemographic, psychosocial, lifestyle, and environmental exposures associated with multiple health indicators. The UK Biobank study recruited >500,000 participants, aged 37-73, between 2006-2010. Health indicators examined were 81 cancer and 443 non-cancer illnesses used to classify participants by health status; long-standing illness; and self-rated health. Exposures were sociodemographic (age, sex, ethnicity, education, income and deprivation), psychosocial (loneliness and social isolation), lifestyle (smoking, alcohol intake, sleep duration, BMI, physical activity and stair climbing) and environmental (air pollution, noise and residential greenspace) factors. 307,378 participants (mean age = 56.1 years [SD = 8.07], 51.9% female) were selected for cross-sectional analyses. Low income, being male, neighbourhood deprivation, loneliness, social isolation, short or long sleep duration, low or high BMI and smoking was associated with poor health. Walking, vigorous-intensity physical activity and more frequent alcohol intake was associated with good health. There was some evidence that airborne pollutants (PM2.5, PM10, and NO₂) and noise (Lden) were associated with poor health, though findings were not consistent across all models. Our findings highlight the multifactorial nature of health, the importance of non-medical factors, such as loneliness, healthy lifestyle behaviours and weight management, and the need to examine efforts to improve health outcomes of individuals with low income.

IMPLICATIONS OF BIOLOGICAL RATES OF AGING ON HEALTHCARE EXPENDITURES AND MORBIDITY

Alix Jean Santos,¹ Xavier Eugenio Asuncion,¹

Natalie Sheils,¹ 1. *OptumLabs, Minnetonka, Minnesota, United States*, 2. *OptumLabs, Eden Prairie, Minnesota, United States*

Understanding biological aging, which entails impeding the progressive decline of biological systems, is important in enabling older adults to live independently. However, the differences in how individuals evolve as they age suggest that aging is a process that does not progress on a single-dimensional trajectory. Moreover, longitudinal studies of aging that follow a cohort of individuals over the course of several years are commonly limited by cost, attrition, and subsequently small sample size. In this study, we used a variational autoencoder to estimate multidimensional rates of aging from cross-sectional routine laboratory data of

1.4 million Americans of at least 40 years of age, collected from 2016 to 2019. We uncovered four aging dimensions that represent the following bodily functions: 1) kidney, 2) thyroid, 3) white blood cells, and 4) liver and heart. We found that fast agers along these dimensions are more likely to develop chronic diseases that are related to these bodily functions. They also had higher health care expenditures compared to the slow agers. K-means clustering of individuals based on the different aging rates revealed that clusters with higher odds of developing morbidity had the highest cost across all types of health care services. Results suggest that cross-sectional laboratory data can be leveraged as an alternative methodology to understand rates of aging along different dimensions, and analysis of their relationships with future costs can aid in the development of interventions to delay disease progression.

LONELINESS AND MARIJUANA USE AMONG OLDER ADULTS: AN EXAMINATION OF THE 2018 HEALTH AND RETIREMENT STUDY

Jie Yang,¹ and Andrew Yockey,² 1. *East Carolina University, Greenville, North Carolina, United States*, 2. *University of North Texas Health Science Center, Denton, Texas, United States*

Introduction: There is substantial literature to suggest that loneliness is a risk factor for marijuana initiation, use, and continued use into adulthood. However, these relationships have yet to be investigated among older adults. Given that recent research suggests marijuana use is increasing among older adults, the purpose of the present study was to examine loneliness and other risk factors among a national sample of older adults ages 50 years or older. **Methods:** A secondary data analysis was conducted on the 2018 Health and Retirement Study (HRS) was conducted (n = 1,431). The HRS is a national, biannual survey conducted in the United States to assess health, psychosocial, and demographic questions among adults ages 50 years or older. We created a loneliness scale from the available questions and assessed differences based on demographics, lifetime use, and past-year use of marijuana. Weighted analyses with cyclical tree-based hot-deck imputation were conducted. **Results:** A sizeable percentage (23.5%) of older adults have ever used marijuana and a considerable amount (14.8%) of adults have used marijuana in the past year. Differences were found based on sex (p < .0001), age (p < .0001), race (p < .0001), and income (p < .0001). Loneliness significantly predicted marijuana usage, with adults who reported loneliness nearly 5 times more likely to use marijuana (aOR: 4.87, 95% CI 3.89, 6.10). **Discussion:** The present study investigated loneliness and marijuana usage among a national sample of adults. Findings from the present study may inform behavioral health interventions, harm reduction, and gerontological health.

OLDER ADULTS SHOW BIOMARKER EVIDENCE OF PICS AFTER SEPSIS

Robert Mankowski,¹ Stephen Anton,² Gabriela Ghita,²

Christiaan Leeuwenburgh,² Lyle Moldawer,² Philip Efron,²

Scott Brakenridge,² and Frederick Moore,² 1. *University of Florida, Gainesville, Florida, United States*, 2. *University of Florida, University of Florida, Florida, United States*

Background: Hospital deaths after sepsis have decreased substantially and most young adult survivors rapidly recover

(RAP). However, many older survivors develop chronic critical illness (CCI) with poor long-term outcomes. The etiology of CCI is multifactorial and the relative importance remains unclear. Sepsis is caused by a dysregulated immune response and biomarkers reflecting a persistent inflammation, immunosuppression and catabolism syndrome (PICS) have been observed in CCI after sepsis. Therefore, the purpose of this study was to compare serial PICS biomarkers in a) older (versus young) adults and b) older CCI (versus older RAP) patients to gain insight into underlying pathobiology of CCI in older adults. Methods: Prospective longitudinal study with young (≤ 45 years) and older (≥ 65 years) septic adults who were characterized by a) baseline predisposition, b) hospital outcomes, c) serial SOFA organ dysfunction scores over 14 days, d) Zubrod Performance status at three, six and 12-month follow-up and e) mortality over 12 months. Serial blood samples over 14 days were analyzed for selected biomarkers reflecting PICS. Results: Compared to the young, more older adults developed CCI (20% vs 42%) and had markedly worse serial SOFA scores, performance status and mortality over 12 months. Additionally, older (versus young) and older CCI (versus older RAP) patients had more persistent aberrations in biomarkers reflecting inflammation, immunosuppression, stress metabolism, lack of anabolism and anti-angiogenesis over 14 days after sepsis. Conclusion: Older (versus young) and older CCI (versus older RAP) patient subgroups demonstrate early biomarker evidence of the underlying pathobiology of PICS.

UROLITHIN A ENHANCES MUSCLE PERFORMANCE IN ELDERLY AND POSITIVELY IMPACTS BIOMARKERS LINKED TO CELLULAR HEALTH

Sophia Liu, and David Marcinek, *University of Washington, Seattle, Washington, United States*

Background: Aging is associated with decline in mitochondrial function and reduced exercise capacity. Urolithin A (UA) is a natural gut metabolite shown to stimulate mitophagy and improve muscle function in aged animals, and induce mitochondrial gene expression in elderly. Purpose: Investigate if oral administration of UA improved walking distance (6MWT), muscle fatigue resistance in hand (FDI) and leg (TA) muscles, and had an impact on plasma biomarkers. Method: We conducted a randomized, double-blind, placebo-controlled study (NCT03283462) in elderly subjects (65-90 yrs.) supplemented daily with 1000mg UA or placebo for 4 months. 128 subjects were screened and 66 randomized. 6MWT and ATPmax via MRS were assessed at baseline and at 4 months. Muscle fatigue tests and plasma analysis of biomarkers were assessed at baseline, 2 and 4 months. Results: UA significantly improved muscle endurance (i.e., change in number of muscle contractions from baseline) in two different muscles (hand: PL 11.6 ± 147.5 , UA 95.3 ± 115.5 ; and leg: PL 5.7 ± 127.1 , UA 41.4 ± 65.5) compared with placebo at 2-months. Plasma levels of several acylcarnitines, ceramides and C-reactive-protein were decreased by UA at the end-of study. 6MWT distance (PL 42.5 ± 73.3 m, UA 60.8 ± 67.2 m) and ATPmax increased in both groups from baseline (PL $13.7 \pm 31.4\%$, UA $19.4 \pm 56.8\%$) with UA supplemented group exhibiting greater improvements, although these were not statistically different between groups. Conclusion: UA supplementation improved muscle endurance, metabolic and

inflammatory plasma biomarkers after 2-months, suggesting that UA can have a positive impact on muscle and cellular health in the elderly.

Session 9095 (Poster)

Biology of Aging: Computational and Systems Approaches to Geroscience

ANALYSIS OF DGAT2 MUTATIONS REVEALS POTENTIAL LINKS BETWEEN CANCER AND LIPID DROPLET DEREGLATION

Meghan Graber, and Hayley Barta, *Xavier University, Cincinnati, Ohio, United States*

Diacylglycerol O-acyltransferase 2 is a transmembrane protein encoded by the DGAT2 gene that functions in lipid metabolism, triacylglycerol synthesis, and lipid droplet regulation. Since cancer cells exhibit altered lipid metabolism, it has been proposed that mutations in DGAT2 may contribute to this state. Using data from the Catalogue of Somatic Mutations in Cancer (COSMIC), we analyzed all reported DGAT2 mutations in human cancers. Bioinformatics analyses were performed to highlight the connections between age, pathogenicity, and cancer tissue type. Mutations are generally associated with samples from older individuals, except for those in glioblastomas which occur earlier. We also found that several DGAT2 mutations fall within the catalytic site of the enzyme and may affect enzyme function. Thus, these mutations may contribute to altered cancer metabolism. We identified D222V as a mutation hotspot neighboring a previously discovered Y223H mutation that causes Axonal Charcot-Marie-Tooth disease. Remarkably, Y223H has not been detected in cancers indicating it is inhibitory to cancer progression. Further analysis showed that most mutations do not affect DGAT2 gene expression suggesting this change is not a major contributor to cancer development. Intriguingly, although most cancers are characterized by low DGAT2 gene expression, some show high expression levels, indicating that, at least in certain cases, over-expression is not inhibitory to cellular proliferation. This work uncovers unknown roles of DGAT2 in cancers and suggests that its function may be more complex than previously appreciated.

ASSOCIATION OF GRIMAGE DNA METHYLATION COMPONENTS AND 2-YEAR MORTALITY IN THE HEALTH AND RETIREMENT STUDY

Helen Meier,¹ Colter Mitchell,² Eileen Crimmins,³ Bharat Thyagarajan,⁴ and Jessica Faul,² 1. *University of Michigan, Ann Arbor, Michigan, United States*, 2. *University of Michigan, University of Michigan, Michigan, United States*, 3. *University of Southern California, Los Angeles, California, United States*, 4. *University of Minnesota, Minneapolis, Minnesota, United States*

DNA methylation (DNAm) patterns related to age and aging phenotypes (i.e., epigenetic clocks) are of growing interest as indicators of biological age and risk of negative health outcomes. We investigated associations between the components of GrimAge, an epigenetic clock estimated from DNAm patterns for seven blood protein levels and smoking pack years, and 2-year mortality in the Health and

Retirement Study (HRS) to determine if any of the DNAm subcomponents were driving observed associations. A representative subsample of individuals who participated in the HRS 2016 Venus Blood Study were included in this analysis (N=3430). DNAm was measured with the Infinium Methylation EPIC BeadChip. Deaths that occurred between 2016 and 2018 contributed to 2-year mortality estimates (N=159, 4.5% of the sample). Weighted logistic regression estimated the association first between GrimAge and 2-year mortality and second between the DNAm subcomponents and 2-year mortality. All models were adjusted for age, sex, race/ethnicity, education, current smoking status, smoking pack years and cell composition of the biological sample. The average GrimAge for participants with and without 2-year mortality was 77 years 68 years respectively. A one-year increase in GrimAge was associated with 17% higher odds of 2-year mortality (95% CI: 1.16, 1.17). Two of the seven DNAm blood protein subcomponents of GrimAge (TIMP metalloproteinase inhibitor 1, adrenomedullin) and DNAm smoking pack years were associated with 2-year mortality and DNAm smoking pack years appeared to drive the overall GrimAge association with 2-year mortality. GrimAge was a better predictor of 2-year mortality than the DNAm subcomponents individually.

GLOBAL PHOSPHOPROTEOMIC PROFILING OF SKELETAL MUSCLE IN OVARIAN HORMONE-DEFICIENT FEMALE MICE

Mina Peyton,¹ Tzu-Yi Yang,¹ LeeAnn Higgins,²

Todd Markowski,¹ Laurie Parker,¹ and Dawn Lowe,¹

1. *University of Minnesota, Minneapolis, Minnesota, United States*, 2. *University of Minnesota, University of Minnesota, Minnesota, United States*

Dynapenia, the age-related loss of skeletal muscle strength without the loss of muscle mass, significantly impacts the activities and quality of life of the aging population. Studies have shown that dynapenia occurs earlier in females than males in both human and rodent studies. Moreover, in females, estrogen deficiency has been shown to contribute to the loss of skeletal muscle strength as well as blunted recovery of strength after injury. The maintenance of skeletal muscle contractile function is vital to the overall health of women, especially as women live 1/3 of their life in an estrogen deficient state. Reversible protein phosphorylation is an indispensable post-translational modification, playing a key role in signal transduction pathways. Phosphorylation of skeletal muscle proteins have been shown to regulate sarcomeric function, excitation-contraction coupling, energy metabolism, and fiber-type composition. To define the physiological changes in the skeletal muscle phosphoproteome associated with estrogen deficiency, we used an ovariectomy model coupled with mass spectrometry. We identified, in total, 5,424 unique phosphorylation sites and 1,177 phosphoproteins in the tibialis anterior muscle. Ingenuity Pathway Analysis show decreased phosphorylation of contractile proteins and significant predicted inhibition of the upstream kinase, CDK6 (z-score -2.0) in ovariectomized compared to control muscles. Our results suggest that estrogen deficiency remodels the skeletal muscle phosphoproteome which may alter phosphorylation signaling that might contribute to the loss of strength in females.

IN SILICO IDENTIFICATION OF ANTI-AGING PHARMACEUTICS FROM COMMUNITY KNOWLEDGE

Samuel Beck, Jun-Yeong Lee, and Jarod Rollins, *MDI*

Biological Laboratory, Bar Harbor, Maine, United States

In this era of Big Data, the volume of biological data is growing exponentially. Systematic profiling and analysis of these data will provide a new insight into biology and human health. Among diverse types of biological data, gene expression data closely mirror both the static phenotypes and the dynamic changes in biological systems. Drug-to-drug or drug-to-disease comparison of gene expression signature allows repurposing/repositioning of existing pharmaceuticals to treat additional diseases that, in turn, provides a rapid and cost-effective approach for drug discovery. Thanks to technological advances, gene expression profiling by mRNA-seq became a routine tool to address all aspects of the problem in modern biological research. Here, we present how drug repositioning using published mRNA-seq data can provide unbiased and applicable pharmaco-chemical intervention strategies to human diseases and aging. In specifics, we profiled over a half-million gene expression profiling data generated from various contexts, and using this, we screened conditions that can suppress age-associated gene expression changes. As a result, our analysis identified various previously validated aging intervention strategies as positive hits. Furthermore, our analysis also predicted a novel group of chemicals that has not been studied from an aging context, and this indeed significantly extended the life span in model animals. Taken together, our data demonstrate that our community knowledge-guided in silico drug-discovery pipeline provides a useful and effective tool to identify the novel aging intervention strategy.

INTERPRETABLE MACHINE LEARNING OF HIGH-DIMENSIONAL AGING HEALTH TRAJECTORIES

Spencer Farrell,¹ Arnold Mitnitski,² Kenneth Rockwood,³ and Andrew Rutenberg,¹ 1. *Dalhousie University, Halifax, Nova Scotia, Canada*, 2. *Dalhousie University, Dalhousie University, Nova Scotia, Canada*, 3. *Dalhousie University, Dalhousie University, Nova Scotia, Canada*

We have built a computational model of individual aging trajectories of health and survival, that contains physical, functional, and biological variables, and is conditioned on demographic, lifestyle, and medical background information. We combine techniques of modern machine learning with an interpretable network approach, where health variables are coupled by an explicit interaction network within a stochastic dynamical system. Our model is scalable to large longitudinal data sets, is predictive of individual high-dimensional health trajectories and survival from baseline health states, and infers an interpretable network of directed interactions between the health variables. The network identifies plausible physiological connections between health variables and clusters of strongly connected health variables. We use English Longitudinal Study of Aging (ELSA) data to train our model and show that it performs better than traditional linear models for health outcomes and survival. Our model can also be used to generate synthetic individuals that age realistically, to impute missing data, and to simulate future aging outcomes given an arbitrary initial health state.

MAMMALIAN CO-METHYLATION NETWORK ANALYSIS OF SPECIES CHARACTERISTICS

Amin Haghani,¹ and Steve Horvath,² 1. *Dept. of Human Genetics, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, USA, Los Angeles, California, United States*, 2. *UCLA, Los Angeles, California, United States*

The comparative cross-species analysis is a powerful tool to resolve the mysteries of evolution and phenotypic disparities among animals. This is the first network analysis of 10,000 DNA methylome data from 176 mammalian species to identify co-methylation modules that relate to individual (age, sex, tissue type) and species characteristics (e.g. phylogenetic order, maximum lifespan, adult weight). The unexpected correlation between DNA methylation and species were sufficiently strong to allow the construction of phyloepigenetic trees that parallel the phylogenetic tree. Weighted correlation network analysis identified 55 distinct co-methylation modules, i.e. sets of highly correlated CpGs. 31 of these modules are readily interpretable in terms of their relationship to age, maximum lifespan, tissue type etc. An age-related module was perturbed by gold standard anti-aging interventions in mice such as caloric restriction or growth hormone receptor knock outs. Our module-based analysis greatly enhances our biological understanding of age-related changes in DNA methylation across many species.

NUCLEAR ARCHITECTURE DISRUPTION DURING AGING CAUSES MISEXPRESSION OF GENES LACKING CPG ISLANDS

Jun-Yeong Lee, Ian Davis, and Samuel Beck, *MDI Biological Laboratory, Bar Harbor, Maine, United States*

Global disorganization of chromatin architecture, characterized by disrupted nuclear lamina and associated heterochromatin, is commonly observed in various aging contexts, including premature aging diseases, cellular senescence, and normative aging. Although these conserved structural changes have been reported for over two decades, their impact on transcription and contribution to age-related degenerative changes remain unclear. Here we show that genes not associated with CpG islands (CGI- genes), which form heterochromatin when transcriptionally silent, are globally misexpressed in aged nuclei with disrupted chromatin architectures. Our data also show that CGI- gene misexpression is a direct outcome of nuclear architecture disruption. Notably, CGI- gene misexpression explains the molecular basis of various defects observed during aging, including loss of cellular identity and increased noises in transcription. We also show that uncontrolled secretory phenotypes commonly observed during aging are largely attributable to CGI- gene misexpression, which drives disruption of intercellular communication and fuel chronic inflammation in aged tissues. Our large-scale meta-analysis further demonstrates that CGI- gene misexpression is a common feature of mammalian aging and age-associated diseases. Interestingly, CGI- gene misexpression can be suppressed by anti-aging interventions. Our study suggests that age-associated CGI- gene misexpression is a novel biomarker of physiological aging which offers an effective therapeutic target for delaying or ameliorating degenerative changes associated with aging.

PROFILING EPIGENETIC AGE IN SINGLE CELLS

Alexandre Trapp,¹ Csaba Kerepesi,² and Vadim Gladyshev,² 1. *Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts, United States*, 2. *Brigham and Women's Hospital, Boston, Massachusetts, United States*

DNA methylation of a defined set of CpG dinucleotides emerged as a critical and precise biomarker of the aging process. Multi-variate machine learning models, known as epigenetic clocks, can exploit quantitative changes in the methylome to predict the age of bulk tissue with remarkable accuracy. However, intrinsic sparsity and digitized methylation in individual cells have so far precluded the assessment of aging in single cell data. We developed scAge, a probabilistic approach to determine the epigenetic age of single cells, and validated our results in mice. scAge tissue-specific and multi-cell type single cell clocks correctly recapitulated the chronological age of the original tissue, while uncovering the inherent heterogeneity that exists at the single-cell level. The data suggested that while cells in a tissue age in a coordinated fashion, some cells age more or less rapidly than others. We showed that individual embryonic stem cells exhibit an age close to zero, that certain stem cells in a tissue showed a reduced age compared to their chronological age, and that early embryogenesis is associated with the reduction of epigenetic age in individual cells, the latter supporting a natural rejuvenation event during gastrulation. scAge is both robust against the low coverage that is characteristic of single cell sequencing techniques and is flexible for studying any cell type and mammalian organism of interest. We demonstrate the potential for accurate epigenetic age profiling at single-cell resolution.

WIDESPREAD CORTICAL DEMYELINATION IN GERIATRIC CASES OF MILD TRAUMATIC BRAIN INJURY AND IN ALZHEIMER'S DISEASE

Andrei Irimia,¹ Nahian Chowdhury,² Shania Wang,² Sean Mahoney,² Van Ngo,² Kenneth Rostowsky,¹ Benjamin Hacker,¹ and Nikhil Chaudhari,² 1. *University of Southern California, University of Southern California, California, United States*, 2. *University of Southern California, Los Angeles, California, United States*

Cortical demyelination is related to neurodegeneration after mild traumatic brain injury (mTBI) and Alzheimer's disease (AD). The ratio R of T1-to-T2-weighted magnetic resonance image (MRI) intensities is proportional to myelin content, and allows myelin changes to be mapped in vivo. T1 and T2 MRIs were acquired from mTBI patients (N = 97, age μ = 41 y; σ = 19 y, range: 21-79) both acutely and chronically (~1 week and ~6 months post-injury, respectively), from AD patients (N = 80, age μ = 76 y; σ = 8 y, range: 55-88), and from cognitively normal (CN) adults (N = 78, age μ = 75 y; σ = 5 y, range: 12-90). AD and CN subjects' data were acquired less than a year apart. MRIs were analyzed using 3DSlicer's BRAINSfit (registration), FreeSurfer (segmentation), SPM12 (bias field correction) and custom MATLAB scripts to calculate myelin content and demyelination. The null hypothesis of no myelin change was tested at each cortical location for each pair of groups (α = 0.05), after accounting for age, sex and interscan interval. Compared to HCs, AD subjects featured significantly greater myelin loss in dorsolateral prefrontal cortex, lateral and medial temporal lobes (~52% of the cortex, p < 0.05).

mTBI participants experienced significantly greater myelin loss across ~96% of the cortex ($p < 0.05$), suggesting that mTBI has dramatic impact upon cortical myelin content. Myelin loss magnitude was comparable across mTBI and AD, particularly within temporal lobes. Future research should study whether post-traumatic demyelination increases the AD risk.

Session 9100 (Poster)

Biology of Aging: Immunity and Aging

ANALYSIS OF SINGLE CELL DATA AS IT RELATES TO AGING AND LONGEVITY

Tanya Karagiannis,¹ Todd Dowrey,² Carlos Villacorta-Martin,³ George Murphy,³ Stefano Monti,² and Paola Sebastiani,⁴ 1. Tufts Medical Center, 2. Boston University, Boston, Massachusetts, United States, 3. Boston University School of Medicine, Boston, Massachusetts, United States, 4. Tufts Medical Center, Physician Organization, BOSTON, Massachusetts, United States

Age-related disability and diseases are known to be delayed in people living to 100 years or more. Changes in the immune system with age are known, including in cell type composition and gene expression differences. To further explore changes in extreme longevity subjects, we investigated peripheral blood immune system cell subpopulations across age and extreme longevity at a single cell resolution. We performed an integrative analysis of public scRNA-seq datasets to define consensus cell types of longevity and age, and classified cell types in our novel New England Centenarian Study dataset. We integrated these datasets together to investigate cell type specific differences at a composition and gene expression level. Our findings identified higher cell type diversity in extreme longevity subjects compared to younger age groups, but no significant difference among younger age groups demonstrating that overall composition differences are unique to longevity. We identified novel differences in myeloid and lymphocyte populations; Extreme longevity subjects have higher composition of CD14+ Monocytes, Natural Killer cells, and T gamma delta populations and lower composition of CD16+ Monocytes and dendritic populations. We characterized gene expression differences between extreme longevity and younger age groups and differences in aging across younger age groups. We found that extreme longevity cell type specific signatures overlapped with the aging signatures by at least 50%. We identified unique genes to extreme longevity that are enriched for pathways specific to immune activation and inflammation, suggesting a protective mechanism for centenarians through efficient activation and regulation of immune subpopulations in peripheral blood.

ASSOCIATION BETWEEN SERUM 25-HYDROXYVITAMIN D LEVELS AND INCIDENCES OF INFECTION IN LONG-TERM CARE

Ronna Robbins,¹ Monica Serra,² and Margaret Briley,³ 1. Audie Murphy VA Medical Center, San Antonio, Texas, United States, 2. UT Health San Antonio - Barshop Institute, San Antonio, Texas, United States, 3. University of Texas at Austin, Austin, Texas, United States

Insufficient serum 25-hydroxyvitamin D (25(OH)D) concentrations are associated with increased respiratory tract infections, influenza, and other infectious diseases. As the world deals with the COVID-19 pandemic, the interest of adequate serum levels to reduce the risk of infection has surfaced. This study determined if the number of infections per year are associated with serum 25(OH)D concentrations in long-term care (LTC). Participants (≥ 65 years) in a cross-sectional study were recruited across five LTC communities in Texas. Medical records were used to collect a one-year medical history using double-blind protocols. Blood draws were collected to measure serum 25(OH)D concentrations. Medical records were used to classify infections based upon documentation of signs and symptoms of infection concurrent with either a physician's note or antibiotic/antiviral medication prescription. Race, BMI, sex, age, and liver and renal disease diagnoses were used as confounders. Of the 177 participants (89% Caucasian, 63% female, mean age 83 years) 69% had ≥ 1 infection over year and 55% had insufficient serum 25(OH)D concentrations < 30 mg/mL (mean 32.6 ng/mL). Linear regression did not show a significant association between serum 25(OH)D concentrations and number of infections (β 0.003; 95% CI -0.014, 0.018; $p=0.760$). Additionally, insufficient serum concentration did not increase the odds of having an infection (OR 1.02; 95% CI 0.05, -19.34; $p=0.987$). This study did not show a significant association between infection rates and serum 25(OH)D concentrations. However, further research is needed to determine if vitamin D supplementation could be an effective therapeutic intervention to reduce infection rates, including COVID-19.

COMBATING AGE-ASSOCIATED IMMUNE DECLINE USING KYNURENINE PATHWAY INTERVENTIONS

Luis Espejo,¹ Destiny DeNicola,² Sam Freitas,² Hope Dang,³ Emily Turner,³ Raul Castro-Portuguez,² Anne Haskins,² and George Sutphin,² 1. UNIVERSITY OF ARIZONA, TUCSON, Arizona, United States, 2. The University of Arizona, Tucson, Arizona, United States, 3. University of Arizona, Tucson, Arizona, United States

Select kynurenine pathway interventions extend lifespan in invertebrate models and are of interest in treating age-associated diseases. Kynurenine pathway activity is responsive to inflammatory signaling, and we are evaluating the potential for these interventions to increase pathogen resistance and curtail age-associated immune decline in *Caenorhabditis elegans* and mammals. The kynurenine pathway facilitates the catabolism of tryptophan to nicotinamide adenine dinucleotide (NAD). Our lab has found that supplementing the kynurenine metabolite 3-hydroxyanthranilic acid (3HAA) or inhibiting the enzyme 3HAA dioxygenase (HAAO) extends lifespan in *C. elegans*. 3HAA has demonstrated pro/anti-inflammatory properties in mammals, suggesting a potential role in immune function. *C. elegans* have a primitive immune system that lacks an adaptive element, but it recapitulates aspects of innate immune signaling and pathogen response. I hypothesize kynurenine pathway interventions that impact *C. elegans* lifespan similarly improve pathogen resistance and immunity. Interventions within the kynurenine pathway are capable of differentially impacting pathogenesis and lifespan of *C. elegans* challenged with *Pseudomonas*

aeruginosa. *C. elegans* subjected to select lifespan-extending kynurenine pathway interventions fared better when challenged with *P. aeruginosa* at older ages. Additionally, fluorescent infection tracking has displayed decreased infection rates in worms with elevated 3HAA. Our data suggests pro-immune activity is facilitated by 3HAA acting downstream of the *dbl-1* pathway in addition to directly inhibiting bacterial growth. Our goal is to discover the mechanism(s) through which the kynurenine pathway interacts with immune function in animals and identify potential targets for clinical therapy in aging populations.

EARLY LIFE THYMECTOMY INDUCES GLUCOSE INTOLERANCE IN MIDDLE-AGED MICE

David Buckley, Sunita Sharma, and Daniel Trott, *University of Texas at Arlington, Arlington, Texas, United States*

Previously we have found that T cells contribute to age-related glucose intolerance. The purpose of this study was to test the hypothesis that early life thymectomy at 3wks of age induces T cell aging and subsequent impairments in glucose homeostasis in otherwise young animals. Male C57BL6 mice underwent thymectomy (thymex; n=7) or sham surgery (control; n=7) at 3wks of age. A glucose (2g/kg) tolerance test (GTT) was performed at 6 and 9mo via intraperitoneal injection. Following euthanasia at 9mo of age, splenic T cell phenotype was assessed by flow cytometry. Group differences were assessed by independent samples t-test or repeated measures ANOVA and Bonferroni post-hoc test. Data are presented as mean±SEM. At 6mo, the thymex animals had a significantly lower fasting glucose compared to controls (156.8±7.9mg/dl, 174.1±5.8mg/dl, p=0.06). During the GTT, 6mo old thymex mice had a greater area under the curve (AUC) compared to controls (31893.8±612.3mg/dl, 28020.9±1112.9mg/dl, p=0.03). At 9mo, the thymex mice had greater fasting glucose compared to controls (215.6±11.6mg/dl, 176.3±7.9mg/dl, p=0.016), as well as a greater GTT AUC (61445.4±1949.2mg/dl, 41527.5±2530.3mg/dl, p=0.0001). The thymex group also had increased fasting and glucose stimulated insulin levels compared to controls (0=1.3±0.2ng/ml, 0.3±0.1ng/ml, p=0.01; 15=1.7±0.2ng/ml, 0.44±0.1ng/ml, p=0.0014). Thymex mice exhibited a blunted splenic CD4:CD8 ratio (0.5±0.2, 1.1±0.2, p=0.04) compared to controls and a trend toward a memory CD8+ T cell phenotype (23.1±11.6%, 7.1±2.6, p=0.08), both consistent with aging. This data indicates that early life thymectomy may accelerate T cell aging, resulting in impairments in glucose tolerance in otherwise young and middle aged mice.

EXPERIENCING A NATURAL DISASTER ACCELERATES AGING OF THE IMMUNE SYSTEM

Marina Watowich,¹ Kenneth Chiou,² Michael Montague,³ Melween Martínez,⁴ James Higham,⁵ Lauren Brent,⁶ Michael Platt,⁷ and Noah Snyder-Mackler,² *1. University of Washington, Tempe, Arizona, United States, 2. Arizona State University, Tempe, Arizona, United States, 3. University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, United States, 4. Medical Sciences Campus- University of Puerto Rico, Sabana Seca, Puerto Rico, United States, 5. NYU, New York University, New York, United States, 6. University of Exeter, Exeter, England, United Kingdom, 7. University of Pennsylvania, Philadelphia, Pennsylvania, United States*

Extreme adverse events such as natural disasters can accelerate disease progression and promote chronic inflammation. These phenotypes also increase in prevalence with age, suggesting that experiencing adversity might accelerate aging of the immune system. Adversity can induce persistent gene regulatory changes which may mechanistically explain the immune similarities between aging and adversity. To test how immune system aging is accelerated following a natural disaster, we measured the impact of Hurricane Maria on peripheral blood immune cell gene expression in a population of free-ranging rhesus macaques (*Macaca mulatta*) from before (n=435) versus after (n=108) Hurricane Maria. Experiencing Hurricane Maria altered the expression of 260 genes (FDR<10%), which were primarily involved in the inflammatory response. There was significant overlap in these hurricane-affected and age-associated genes with 40% (n=104) being associated with both the hurricane and aging, more than double the expected amount (Fisher's Exact Test OR=3.7, p=4.06 x 10⁻²¹). The effects of the hurricane and aging on gene expression were also significantly correlated (rho=0.23, p=1.33 x 10⁻⁸⁴), suggesting that they alter similar molecular pathways in the immune system. Further, we found that animals that experienced the hurricane had a gene expression profile that was, on average, 1.6 years older than animals that did not experience the hurricane (the equivalent of 6–7 years in a human lifespan, p=0.003). Together, our results provide some of the first evidence that extreme natural disasters mechanistically accelerates aging in the immune system.

HEMATOPOIETIC MOSAIC CHROMOSOMAL ALTERATIONS IN THE NEW ENGLAND CENTENARIAN STUDY.

Anastasia Leshchik,¹ Giulio Genovese,² Stefano Monti,³ Thomas Perls,³ and Paola Sebastiani,⁴ *1. Boston University, Brookline, Massachusetts, United States, 2. Broad Institute, Boston, Massachusetts, United States, 3. Boston University, Boston, Massachusetts, United States, 4. Tufts Medical Center, Physician Organization, BOSTON, Massachusetts, United States*

Mosaic chromosomal alterations (mCAs) are structural alterations that include deletions, duplications, or copy-neutral loss of heterozygosity. mCAs are reported to be associated with survival, age, cancer, and cardiovascular disease. Previous studies of mCAs in large population-based cohorts (UK Biobank, MGBB, BioBank Japan, and FinnGen) have demonstrated a steady increase of mCAs as people age. The distribution of mCAs in centenarians and their offspring is not well characterized. We applied MOsaic CHromosomal Alteration (MoChA) caller on 2298 genome-wide genotype samples of 1582 centenarians, 443 centenarians' offspring, and 273 unrelated controls from the New England Centenarian Study (NECS). Integrating Log R ratio and B-allele frequency (BAF) intensities with genotype phase information, MoChA employs a Hidden Markov Model to detect mCA-induced deviations in allelic balance at heterozygous sites consistent with genotype phase in the DNA microarray data. We analyzed mCAs spanning over 100 k base pairs, with an estimated cell fraction less than 50%, within samples with genome-wide BAF phase concordance across phased heterozygous sites less than 0.51, and with LOD score of more than 10 for the model based on BAF and

genotype phase. Our analysis showed that somatic mCAs increase with older age up to approximately 102 years, but the prevalence of the subjects with mCAs tend to decrease after that age, thus suggesting that accumulation of mCAs is less prevalent in long-lived individuals. We also used Poisson regression to show that centenarians and their offspring tend to accumulate less mCA (RR = 0.63, $p=0.045$) compared to the controls.

IMMUNE CELL AND ADIPOSE GENE EXPRESSION REPROGRAMMING IN JUVENILE MONKEYS BORN TO HEALTH AND WEIGHT-DIVERSE MOTHERS

Alistaire Ruggiero, Masha Block, Ravichandra Vemuri, Darla DeStephanis, Swapan Das, and Kylie Kavanagh, *Wake Forest School of Medicine, Winston-Salem, North Carolina, United States*

Over 93 million Americans are obese and 66 million suffer from metabolic disease. Roughly 40% of obese people do not have metabolic abnormalities (metabolically healthy obese [MHO]), while approximately 15% of lean do (metabolically unhealthy lean [MUL]). African green monkeys (AGMs) demonstrate naturally occurring obesity and metabolic syndrome (MetS) without diet manipulation, and MetS criteria are heritable. Age-matched maternal AGMs were classified by adjusted MetS criteria ($n=44$); waist >40 cm, fasting glucose (FG) >100 mg/dL, SBP/DBP $>135/85$ mmHg, and HDL-c <50 mg/dL) and classified as metabolically healthy lean (MHL), MHO, MUL or metabolically unhealthy obese (MUO). Age, weight and sex-matched pre-pubertal juvenile offspring from these mothers were additionally selected ($n=9-11$ /group; ages=1.1-3.4years) for evaluation. We assessed monocyte subtypes by flow cytometry, and subcutaneous adipose gene expression patterns by RNAseq. Non-classical monocytes were increased in obese and unhealthy mothers (MHO $p=0.02$, MUL $p=0.003$, MUO $p=0.00002$) compared to MHL. MUL and MUO juvenile offspring also had more non-classical monocytes compared to MHL ($p=0.05$ and $p=0.07$). Monocyte chemoattractant protein-1 (MCP)-1 was measured in plasma and found to be elevated in MUO juveniles ($p=0.02$). Patterns of increased cytokine and extracellular matrix gene expression were seen in MUL and MUO juveniles' adipose (6-7/group), mirroring obese and unhealthy mothers' adipose gene expression patterns. Maternal health and obesity influence offspring immune cells and adipose gene expression prior to weight gain and metabolic disease onset. Our data underscore maternal monocyte and adipose profiles as inherited phenotypes that present prior to adipose expansion and may be targets to improve intergenerational health trajectories.

THE ROLE OF THE HUMAN IMMUNE SYSTEM IN THE AGING PROCESS: A MATHEMATICAL MODEL OF CELL AND CYTOKINE ACTIVATION

Kian Talaei,¹ Steven Garan,¹ Nuno Martins,¹ Joshua Cho,² Julia Jahansooz,² Puneet Bhullar,³ Elliott Suen,⁴ and Walter Piszker,² 1. *University of California, Berkeley, Center for Research and Education in Aging, University of California, Berkeley, California, United States*, 2. *University of California, Berkeley, Berkeley, California, United States*, 3. *Mayo Clinic, Scottsdale, Arizona, United States*, 4. *UC Berkeley, Berkeley, California, United States*

The role of the human immune system as a factor in the aging process has led to extensive research in the field of infection biology and bioinformatics. Cell-based mathematical models have previously been used to simulate the immune system in response to pathogens. A variety of cells, such as activated and resting macrophages, plasma cells, antibodies, helper T cells, T-lymphocytes, and B-lymphocytes, have already been simulated by mathematical models. This work aims to incorporate cytokines in these mathematical models to create a more comprehensive simulation that can predict cytokine levels in response to a Gram-positive bacterium, *S. aureus*. To accomplish this, the cytokines Tumor Necrosis Factor Alpha (TNF- α), Interleukin 6 (IL-6), Interleukin 8 (IL-8), and Interleukin 10 (IL-10) were studied to quantify the relationship between cytokine release from macrophages and the concentration of the pathogen, *S. aureus* ex vivo. The results of the simulation were compared to ex vivo human whole blood data to test its accuracy. The future expansion of this model may provide a clearer image of the various interactions within the immune system and this improved model of the immune system may also facilitate a better understanding of the mechanisms that lead to the degradation of the immune system during the aging process.

Session 9105 (Poster)

Biology of Aging: Interventions

3-HYDROXYANTHRANILIC ACID ADMINISTRATION DID NOT PREVENT AGE RELATED BONE LOSS

Carlos Isales,¹ Ke-Hong Ding,² Wendy Bollag,³ Meghan McGee-Lawrence,⁴ William Hill,⁵ Xing-ming Shi,³ Sadanand Fulzele,¹ and Mark Hamrick,¹ 1. *Medical College of Georgia, Augusta, Georgia, United States*, 2. *Augusta University, Augusta, Georgia, United States*, 3. *Augusta University, Augusta, Georgia, United States*, 4. *Medical College of Georgia, Augusta University, Augusta, Georgia, United States*, 5. *Medical University of South Carolina, Charleston, South Carolina, United States*

Aging is associated with accumulation of various tryptophan degradation products that may having either bone anabolic or catabolic effects. In epidemiologic studies, elevated levels of 3-hydroxyanthranilic acid (3-HAA) are associated with a higher bone mineral density (BMD). We have previously shown that the C57BL/6 mouse loses bone mass with age. Thus, we hypothesized that administering 3-HAA via a daily intraperitoneal (IP) injection would result in preserved or increased BMD. In an IACUC-approved protocol, we injected 26-month-old C57BL/6 mice with either a low dose (0.5 mg) or high dose (5 mg) of 3-HAA IP five days a week for eight weeks. At the end of this time mice were sacrificed and body composition and bone mineral density measured by DigiMus. BMD was significantly lower in the high dose 3-HAA group: $0.0570 + 0.004$ vs $0.0473 + 0.006$ vs $0.0432 + 0.0075$ gm/cm², (means+SD, Control vs 0.5 mg 3HAA vs 5 mg 3HAA, $p=0.004$, 0 vs 5.0 mg, $n=6-9$ /group). 3-HAA had no significant impact on body composition (lean body mass: $86.7 + 1.7\%$ vs $86.2 + 2.7\%$ vs $86.1 + 2.0\%$, Control vs 0.5 mg vs 5.0 mg 3-HAA, $p=ns$; and fat mass $12.6 + 2.0\%$ vs $13.8 + 2.7\%$ vs $13.9 + 2.0\%$ vs 0.2% ,

Control vs 0.5 vs 5 mg 3-HAA, $p=ns$). Thus, 3-HAA did not prevent bone loss in older mice but instead significantly worsened bone loss. 3-HAA is known to have both pro- and anti-oxidant effects depending on the environment. These data would suggest that at the higher concentrations 3-HAA is acting predominantly as a pro-oxidant molecule accelerating age-related bone loss.

ASSOCIATION BETWEEN MEETING PHYSICAL ACTIVITY GUIDELINES WITH AMBULATION AND QUALITY OF LIFE IN CLAUDICATION

Andrew Gardner,¹ Polly Montgomery,¹ Ming Wang,² Biyi Shen,² Shangming Zhang,² and William Pomilla,²

1. Penn State College of Medicine, Hummelstown, Pennsylvania, United States, 2. Penn State College of Medicine, Penn State College of Medicine, Pennsylvania, United States

We determined if meeting the 2018 physical activity guidelines was associated with better ambulatory function, health-related quality of life, and inflammation than failing to meet the guidelines in patients with peripheral artery disease and claudication. Secondly, we determined the optimal number of total daily steps that are needed to meet the physical activity guidelines. Five hundred seventy-two patients were assessed on their daily ambulatory activity for one week with a step activity monitor, and were grouped according to whether they achieved less than 150 minutes of moderate intensity physical activity per week (Group 1=Do Not Meet Guidelines; $n=397$), or whether they were above this threshold (Group 2=Meet Guidelines; $n=175$). Treadmill peak walking time (mean \pm SD) was significantly higher ($p<0.001$) in Group 2 (709 \pm 359 sec) than in Group 1 (427 \pm 281 sec). The health-related quality of life score for physical function was significantly higher ($p<0.001$) in Group 2 (61 \pm 22%) than in Group 1 (44 \pm 21%). High sensitivity C-reactive protein was significantly lower ($p<0.001$) in Group 2 (3.6 \pm 4.5 mg/L) than in Group 1 (5.9 \pm 6.1 mg/L). Finally, 7,675 daily steps was the optimal threshold associated with meeting the physical activity guidelines, with a sensitivity of 82.9% and a specificity of 88.4%. In conclusion, patients with claudication who meet the 2018 physical activity guidelines for US adults had better ambulation, HRQoL, and inflammation outcomes than those who failed to meet the guidelines. From a practical standpoint, patients with claudication best achieved the physical activity guidelines by taking a total of 7,675 daily steps.

BENEFICIAL EFFECTS OF A PLASMA FRACTION ON INFLAMMATION AND SYNAPTIC DEFICITS FOR AGE-RELATED COGNITIVE DISORDERS

Ian Gallager, Jasmine Torres, Raniel Alcantara-Lee, Chirag Thadani, Rachel Britton, Eva Czirr, Steven P Braithwaite, and Viktoria Kheifets, *Alkabest Inc., San Carlos, California, United States*

The process of aging is multifactorial, and therefore single agent interventions would be unlikely to attenuate the myriad pathologies associated with advancing age. Plasma contains many beneficial factors which have been shown in animal models to ameliorate multiple age-related deficits across varied organ systems, including the brain. We confirmed that human plasma from young (18-22-year-old) donors reverses

age-related cognitive decline and enhances hippocampal neurogenesis and cell survival in aged immunocompromised mice, while plasma from aged individuals (62-68 years old) has detrimental effects in young mice. We examined PF in a high-fat diet (HFD) mouse model, a surrogate for a western diet, which expresses many characteristics of aging within the CNS in an accelerated manner: decreased cell proliferation, synaptic connectivity and increased inflammation compared to normal diet (NC) controls. We demonstrate that PF administration in HFD mice resulted in decreased brain inflammation, increased synaptic connectivity, improved neural progenitor cell survival, as well as amelioration of behavioral endpoints without impacting the underlying metabolic changes induced by HFD. In summary, we demonstrate that PF is a multifactorial and multimodal intervention for the treatment of global changes induced by the process of aging.

BOTH VITAMIN D SUPPLEMENTATION AND HIIT BOOST MUSCLE VDR EXPRESSION, WHICH MAY UNDERLIE BENEFITS FOR FRAILTY

Ken Seldeen, Ramkumar Thiagarajan, Merced Leiker, Reem Berman, Yonas Redae, Carleara Weiss, Lee Chaves, and Bruce Troen, *University at Buffalo, Buffalo, New York, United States*

Frailty is a condition of poor response to stressors that increases susceptibility to adverse outcomes - including disability and death. Declining physical function is an important hallmark of frailty, and we previously published that long term vitamin D insufficiency from young to middle-age leads to declines in endurance and gait disturbances. Furthermore, we report that aged mice (24-months) made vitamin D insufficient for 4 months exhibit increased frailty, whereas those made hyper-sufficient do not. Exercise, including short session high intensity interval training (HIIT - 10 minutes/3x-week), also reverses frailty in aged mice. Here we investigate the impacts of aging, vitamin D, and exercise on underlying muscle quality and muscle stem cell activity. Our preliminary data reveal muscle vitamin D receptor (VDR) expression is lower in aged mice (24-28 months) relative to young mice (6 months). Yet HIIT, either one hour after a single session or following 6 weeks, increases VDR expression. HIIT also increases myonuclear accretion in muscle fibers - an indicator of in vivo stem cell activity - and stimulates progenitor cells proliferation ex vivo. Likewise, we observe that vitamin D hyper supplementation alone also increases muscle VDR expression and the number of satellite cells. These data indicate that both vitamin D supplementation and HIIT independently enhance VDR expression in skeletal muscle with associated greater satellite and muscle progenitor cell activity. These data critically link vitamin D physiology and HIIT in muscle, and thus provide a mechanistic basis for their benefits for muscle quality, function, and health during aging.

CHRONIC EXPOSURE TO YOUTHFUL CIRCULATION LEADS TO EPIGENETIC REPROGRAMMING AND LIFESPAN EXTENSION

Bohan Zhang,¹ David Lee,² Alexander Tyshkovskiy,³ Akshay Bareja,² Csaba Kerepesi,¹ Steve Horvath,⁴ Vadim Gladyshev,¹ and James White,² 1. *Brigham and Women's Hospital, Boston, Massachusetts, United States*, 2. *Duke University School of Medicine, Durham, North*

Carolina, United States, 3. Moscow State University, Moscow, Moskva, Russia, 4. UCLA, Los Angeles, California, United States

Heterochronic parabiosis is a powerful rejuvenation model in aging research. Due to limitations in the duration of blood sharing and/or physical attachment, it is currently unclear if parabiosis retards the molecular signatures of aging or affects healthspan/lifespan in the mouse. Here, we describe a long-term heterochronic parabiosis model, which appears to slow down the aging process. We observed a “deceleration” of biological age based on molecular aging biomarkers estimated with DNA methylation clock and RNA-seq signature analysis. The slowing of biological aging was accompanied by systemic amelioration of aging phenotypes. Consistent with these findings, we found that aged mice, which underwent heterochronic parabiosis, had an increased healthspan and lifespan. Overall, our study re-introduces a prolonged parabiosis and detachment model as a novel rejuvenation therapy, suggesting that a systemic reset of biological age in old organisms can be achieved through the exposure to young environment.

DIET AND STRESS IMPAIR OVARIAN FUNCTION IN MID-LIFE, INCREASING RISK OF CHRONIC DISEASES OF AGING IN PRIMATES

Brett Frye, Suzanne Craft, Thomas Register, Susan Appt, Mara Vitolins, Beth Uberseder, Marnie Silverstein-Metzler, and Carol Shively, *Wake Forest School of Medicine, Winston Salem, North Carolina, United States*

Ovarian dysfunction increases risk for chronic diseases of aging including cardiovascular disease, depression, cognitive impairment, and bone and muscle loss which promote frailty. Psychosocial stress disrupts ovarian function and recent observations suggest that Western diet may also. Determination of causal relationships among diet, psychosocial stress, and ovarian physiology is difficult in humans. Nonhuman primates provide relevant opportunities to investigate diet and psychosocial effects on ovarian physiology and aging because, like humans, they have monthly menstrual cycles and recapitulate many aging-related processes similar to humans. We examined ovarian function in 38 socially housed, middle-aged females fed either a Western or Mediterranean diet for 26 months (~an 8-year period for humans). During the last 12 months, we examined cycle length, peak progesterone per cycle, and frequency of anovulatory cycles using blood sampling (3/week) and vaginal swabbing (6/week). Repeated measures analysis revealed that like middle-aged women, cycle length increased, and progesterone levels fell over time, suggesting that ovarian dysfunction generally increased in our sample with time. In addition, both Western diet and the stress of low social status reduced progesterone levels, disrupting ovarian function, and increasing risk of chronic diseases of aging. This study demonstrates the additive negative effects of poor diet and psychosocial stress on ovarian physiology in mid-life and lays the groundwork for future investigations to uncover associated metabolic signatures of accelerated aging. The results also suggest that a Mediterranean diet may exert a protective influence against ovarian dysfunction and its pathologic sequelae.

EXERCISE DURING CHILDHOOD PROTECTS AGAINST CARDIAC DYSFUNCTION LATER IN LIFE

Danielle Bruns,¹ MacKenzie DeHoff,¹ Aykhan Yusifov,¹ Sydney Polson,¹ Ross Cook,¹ Emily Schmitt,¹ and Kathleen Woulfe,² 1. *University of Wyoming, Laramie, Wyoming, United States*, 2. *University of Colorado-Denver, Aurora, Colorado, United States*

Cardiovascular disease continues to be a major cause of morbidity and mortality, particularly in aging populations. Exercise is amongst the most cardioprotective interventions identified to date, with early in life exercise such as during the juvenile period potentially imparting even more cardioprotective outcomes due to the plasticity of the developing heart. To test the hypothesis that juvenile exercise would impart later in life cardioprotection, we exercised juvenile male and female mice via voluntary wheel running from 3-5 weeks of age and then exposed them to cardiac stress by isoproterenol (ISO) at 4-6 and 18 months of age in adulthood and older age, respectively. We compared cardiac function and remodeling to sedentary control animals, sedentary animals who received ISO, and adult and aged mice that exercised for two weeks immediately before ISO exposure. Juvenile mice engaged in voluntarily wheel running, with male mice running 1.3 ± 0.8 km and female mice 2.8 ± 1.0 km a day. Echocardiography suggested that these juvenile animals underwent running-induced cardiac remodeling as evidenced by higher ejection fraction and stroke volume compared to sedentary controls. Exercise in the juvenile period attenuated ISO-induced cardiac hypertrophy and remodeling later in life compared to sedentary animals and those that exercised immediately before ISO administration. The mechanisms by which early versus late exercise is protective in adult and aged mice are under investigation. Further ongoing work will identify the adaptations induced by exercise in the juvenile heart that may help improve cardiac aging.

EXERCISE-INDUCED TRANSCRIPTIONAL CHANGES IN AGED SKELETAL MUSCLE

Yori Endo,¹ Yuteng Zhang,² Shayan Olumi,³ Mehran Karvar,² and Indranil Sinha,⁴ 1. *Harvard Medical School, Boston, Massachusetts, United States*, 2. *Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts, United States*, 3. *Northwestern University, Evanston, Illinois, United States*, 4. *Birgham and Women's Hospital, Harvard Medical School, Boston, Massachusetts, United States*

Exercise is beneficial for physical functions across all ages. However, the response to exercise shifts from anabolism, resulting in limited gain of muscle strength and endurance. These changes likely reflect age-related alterations in transcriptional response underlying the muscular adaptation to exercise. The exact changes in gene expression accompanying exercise, however, are largely unknown, and elucidating them is of a great clinical interest for optimizing the exercise-based therapies for sarcopenia. In order to characterize the exercise-induced transcriptomic changes in aged muscle, a paired-end RNA sequencing was performed on the rRNA-depleted total RNA extracted from the gastrocnemius muscles of 24 months-old mice after 8 weeks of regimented exercise (exercise group) or sedentary activities (sedentary group). Differential gene expression analysis revealed

upregulations in the group of genes involved in neurotransmission. In particular, genes encoding the transporters and receptor components of glutaminergic transmission were significantly upregulated in exercised muscles, as exemplified by *Gria 1*, *Gria 2* and *Grin2c* encoding glutamate receptor 1, 2 and 2C respectively, *Grin1* and *Grin2b* encoding N-methyl-D-aspartate receptors (NMDARs), *Nptx1* responsible for glutaminergic receptor clustering, and *Slc1a2* and *Slc17a7* regulating synaptic uptake of glutamate. These changes were accompanied by an increase in post-synaptic NMDARs and acetylcholine receptors (AChRs), as well as their innervation at neuromuscular junctions (NMJs). These results suggest that neural responses predominate aged skeletal muscle following exercise, and indicate a possibility that glutaminergic transmission at NMJs may be responsible for synaptic protection and neural remodeling accompanying the exercise-induced functional enhancement in aged skeletal muscle.

GENES CONTRIBUTING TO RESILIENCE AND SENSITIVITY TO LISINAPRIL AT OLD AGE: CLINICAL TRANSLATION OF GWA IN DROSOPHILA

Mariann M. Gabrawy,¹ Nick Khosravian,² George S. Morcos,³ Meagan Jezek,² Jeremy Walston,¹ Peter M. Abadir,¹ and Jeff Leips,² 1. *Johns Hopkins University School of Medicine, Baltimore, Maryland, United States*, 2. *University of Maryland Baltimore County, Baltimore, Maryland, United States*, 3. *University of Maryland School of Medicine, Baltimore, Maryland, United States*

Despite impressive results in restoring physical performance in rodent models, treatment with Renin-Angiotensin System (RAS) inhibitors such as Lisinopril have highly mixed results in humans, likely, in part, due to genetic variation in human populations. To date, the genetic determinants of responses to drugs such as RAS inhibitors remain unknown. Given the complexity of the relationship between physical traits and genetic background, genomic studies which predict genotype- and age-specific responses to drug treatments in humans or vertebrate animals are difficult. Here, using 126 genetically distinct lines of *Drosophila*, we tested the effects of Lisinopril on climbing speed and endurance at young and old age (N=14,310). Our data show that functional response and sensitivity to Lisinopril ranges from significant protection against physical decline (8–100% faster, $P < 0.0001$) to increased weakness ($P < 0.0001$) depending on both genotype and age ($P < 0.0001$). Genome-wide analyses revealed little to no overlap in candidate polymorphisms influencing sensitivity between ages nor between treatments within each age. Furthermore, network analyses led to identification of evolutionarily conserved genes in the WNT signaling pathway as being significantly associated with variations in sensitivity to Lisinopril. Genetic knockdown of *Axin*, *frizzled*, *nemo*, and *wingless*, genes with human orthologs *AXIN1*, *FZD1*, *NLK*, and *WNT1*, respectively, abolished the effects of Lisinopril treatment. Our results implicate these genes as contributors to the genotype- and age-specific effects of Lisinopril treatment and as potential therapeutic targets for improvement of resiliency. Our approach should be widely applicable for identifying genomic variants that predict age-dependent responses to pharmaceutical treatments.

IMMATURE PEAR EXTRACT CONSTITUENTS EXERT MULTIFACETED ANTI-AGING EFFECTS

Akira Ogita,¹ Wakae Murata,² Ken Yamauchi,³ Akiko Sakai,¹ Yoshihiro Yamaguchi,¹ Toshio Tanaka,¹ and Ken-ichi Fujita,¹ 1. *Osaka City University, Osaka, Osaka, Japan*, 2. *Yonago National College of Technology, Yonago, Tottori, Japan*, 3. *Keio University, Yokohama, Kanagawa, Japan*

Cellular senescence causes a gradual loss of physiological functions and induces chronic diseases, which negatively affect the quality of human life. Intervention in the cellular senescence process may reduce the incidence of these diseases while delaying the progression of age-related diseases, thereby prolonging human lifespan. In our previous study, we found that extending the chronological lifespan of budding yeast cells, a suitable cellular model for research on mammalian cells, could be achieved by adding immature pear extract (iPE). Moreover, at the 2020 GSA meeting, using a colony-counting method, we reported that both hydrophilic (WiPE) and hydrophobic (OiPE) iPE components exhibited a chronological lifespan prolongation on yeast cells. In this study, the expression of sirtuin-related genes, which regulate cellular senescence, was verified by quantitative real-time reverse-transcription polymerase chain reaction. Interestingly, sirtuin-related gene expression was significantly increased in the WiPE-treated cells only, and OiPE could extend the chronological lifespan of yeast cells through the mechanisms not involved in sirtuin-related gene expression. In general, hydrophobic and hydrophilic components exhibit different degradation and metabolism in cells. Since each component has a different strategy of absorption and excretion in the body, we hypothesize that iPE with multiple active components will have multifaceted effects on anti-aging. Our research on elucidating the mechanism of lifespan extension by OiPE and its application to mammalian cells is ongoing.

KYNURENINE METABOLISM LIFESPAN EXTENSION MEDIATED BY OXIDATIVE STRESS RESPONSE AND HYPOXIC RESPONSE IN C. ELEGANS

Raul Castro-Portuguez,¹ Jeremy Meyers,² Sam Freitas,¹ Hope Dang,² Emily Turner,² Destiny DeNicola,¹ Luis Espejo,³ and George Sutphin,¹ 1. *The University of Arizona, Tucson, Arizona, United States*, 2. *University of Arizona, Tucson, Arizona, United States*, 3. *UNIVERSITY OF ARIZONA, TUCSON, Arizona, United States*

Aging is characterized by a progressive decline in the normal physiological functions of an organism, ultimately leading to mortality. Metabolic changes throughout the aging process disrupt the balance and homeostasis of the cell. The kynurenine metabolic pathway is the sole de novo biosynthetic pathway for producing NAD⁺ from ingested tryptophan. Altered kynurenine pathway activity is associated with both aging and a variety of age-associated diseases, and kynurenine-based interventions can extend lifespan in *Caenorhabditis elegans*. Our laboratory recently demonstrated knockdown of the kynurenine pathway enzymes kynureninase (KYNU) or 3-hydroxyanthranilic acid dioxygenase (HAAO) increases lifespan by 20-30% in *C. elegans*. However, the mechanism of how these interventions may modulate response against different stressors during the aging process has yet to be explored. Fluorescent reporter

strains show the stress-responsive transcription factors skn-1 (ortholog of NRF2/NFE2L2; oxidative stress response) and hif-1 (ortholog of HIF1A; hypoxic stress response) to be highly upregulated when the kynurenine pathway is inhibited. We also demonstrated the increase expression of *gst-4* and *gcs-1* (transcriptional targets skn-1), which are involved in production of the antioxidant glutathione (GSH), as well as upregulation of *cysl-2* (transcriptional target of hif-1), a regulator of cysteine biosynthesis from serine. We hypothesize that lifespan extension resulting from kynurenine pathway inhibition is mediated, at least in part, by upregulation of these transcription factors, providing elevated defense against oxidative stress and hypoxic stress.

LOSARTAN MITIGATES OXIDATIVE STRESS IN THE BRAINS OF AGED IL10^{-/-} MICE

Nazaneen Saleh,¹ Caglar Cosarderelioglu,² Ramya Vajapey,³ Jeremy Walston,⁴ and Peter M. Abadir,⁴ 1. *University of Virginia, Springfield, Virginia, United States*, 2. *Ankara University School of Medicine, Cankaya, Ankara, Turkey*, 3. *The Cleveland Clinic Foundation, Cleveland, Ohio, United States*, 4. *Johns Hopkins University School of Medicine, Baltimore, Maryland, United States*

Chronic inflammation has been linked to frailty and declined cognition in older adults. Activation of the renin-angiotensin system (RAS) through the angiotensin Type1 receptor (AT1R) has been suggested as a contributory factor that links both inflammation and aging. Here we examined the impact of 4 weeks of oral Losartan treatment on IL10^{-/-} mice brains, a mouse model of chronic inflammation and frailty. Frontal cortex, cerebellar, and hippocampal tissue of aged (100 weeks old) male IL10^{-/-} mice were studied. Western blot techniques were employed to quantify changes in brain AT1R, nitrotyrosine (NT) as an oxidative stress marker, and Tau proteins. Our data show that aged IL-10 mice have significantly higher levels of AT1R in the cortex tissue but not in cerebellar or hippocampal tissue compared to age and sex-matched WT mice (0.63 + 0.35 vs 1.5 + 0.54, WT vs IL10, respectively, P<0.004). When treated with LOS, brain cortical tissue of IL10^{-/-} mice showed significant decreases in levels of AT1R (1.5 + 0.54 vs 0.98 + 0.50, IL10 vs LOS treated IL10, respectively, P<0.04), NT (0.72 + 0.12 vs 0.42 + 0.10, IL10 vs LOS treated IL10, respectively, P<0.009), and Tau protein (1.3 + 0.31 vs 0.15 + 0.08, IL10 vs LOS treated IL10, respectively, P<0.004) as compared to control IL10^{-/-} mice. Losartan treatment had no significant effect on hippocampal AT1R or NT levels. Our results highlight the impact of Losartan, a drug commonly prescribed for the treatment of high blood pressure, on the brain-specific angiotensin system and its downstream effects on brain oxidative stress and Tau pathology.

LOSS OF HYPOXIA SIGNALING LIMITS PHYSIOLOGIC AND MUSCLE ADAPTATIONS TO AEROBIC EXERCISE IN AGING

Yori Endo,¹ Mehran Karvar,² Yuteng Zhang,² Shayan Olumi,³ and Indranil Sinha,⁴ 1. *Harvard Medical School, Boston, Massachusetts, United States*, 2. *Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts, United States*, 3. *Northwestern University, Evanston, Illinois, United States*, 4. *Brigham and Women's*

Hospital, Harvard Medical School, Boston, Massachusetts, United States

To assess the differential effects of exercise with age, Young (Y, 10-12 weeks) and Old (O, 23-25 months) mice were subjected to regimented treadmill running or no regimented exercise. Y, trained mice experienced a significant increase in maximal distance running, maximal speed of running, and lean muscle mass in comparison to age-matched, untrained controls. O mice did not improve significantly in any of these measures following training. Transcriptome analysis of gastrocnemius from Y mice demonstrated differential regulation of 120 genes with exercise. None of these genes were similarly regulated in the O group. Genes most upregulated following exercise in Y mice were direct targets of the hypoxia signaling pathway. Immunoblotting demonstrated that aryl hydrocarbon receptor nuclear translocator (ARNT), a critical regulator of hypoxia signaling, increased 3-fold with exercise in Y mice, but this increase was absent in O mice following exercise. To assess whether this loss of ARNT in O muscle impaired the exercise response, we generated a mouse with inducible, skeletal muscle-specific knockout of ARNT (ARNT muscle (m) KO). Following regimented exercise, ARNT mKO mice did not improve maximal distance running, maximal running speed, or lean muscle mass in comparison to untrained ARNT mKO mice. Littermate, age-matched ARNT wild type mice increased significantly in all of these measures following training. Administration of ML228, an ARNT agonist, increased maximal running distance and speed in response to exercise training in O mice. These results suggest that restoration of ARNT and hypoxia signaling may restore the physiologic response to exercise in aging.

MECHANISMS OF CELL NON-AUTONOMOUS LONGEVITY REGULATION

Scott Leiser,¹ Hyo Choi,¹ Hillary Miller,¹ Ajay Bhat,² Marshall Howington,² Elizabeth Dean,² and Shijiao Huang,² 1. *University of Michigan, Ann Arbor, Michigan, United States*, 2. *University of Michigan, University of Michigan, Michigan, United States*

An organism's ability to respond to stress is crucial for long-term survival. These stress responses are coordinated by distinct but overlapping pathways, many of which also regulate longevity across taxa. Our previous work identified a cell non-autonomous signaling pathway led by the hypoxia-inducible factor and resulting in induction of flavin-containing monooxygenase-2 (*fmo-2*) to promote health and longevity. Our current work identifies a distinct cell non-autonomous pathway downstream of dietary restriction (DR) that also relies on *fmo-2* induction to promote health and longevity. We now find that these cell non-autonomous pathways can be mimicked by small molecule interventions that increase longevity by inducing *fmo-2*. Based on the commonalities of these pathways, we hypothesized that *fmo-2*, a classically annotated xenobiotic enzyme, might play a key endogenous role in responding to metabolic stress. Our resulting data, using metabolic profiling and further epistatic analysis, both support this hypothesis and link *fmo-2*'s mechanism to modifications in one-carbon metabolism (OCM), a key intermediate pathway consisting of the folate and methionine cycles. Using mathematical modeling and a labeled

metabolomics approach, we were able to further identify the likely mechanism of fmo-2-mediated metabolic effects and connect them to both OCM and downstream components. We propose that fmo-2 is induced cell non-autonomously to modify systemic metabolism and longevity, and that fmo-2 is a key member of a conserved metabolic stress response.

MODERATE CALORIE RESTRICTION ENHANCES HEPATIC GLUCAGON SENSITIVITY IN AGED MICE

Tyler Marx, Luke Safayan and Jennifer Stern, *University of Arizona, Tucson, Arizona, United States*

Chronic calorie restriction (CR) without malnutrition delays the onset of aging, extends lifespan, and improves metabolic function in many species. These CR-induced benefits have largely concentrated on the role of insulin signaling, while ignoring its counter-regulatory hormone, glucagon. Like insulin, hyperglucagonemia and decreased glucagon sensitivity are associated with impaired glucose homeostasis and decreased longevity. Conversely, activation of target molecules downstream of glucagon signaling such as AMPK and FGF21 are known to ameliorate these age-related impairments in metabolic function. To investigate the potential role of glucagon receptor signaling in CR-induced improvements in aging, we have implemented a moderate 15% CR in the mouse. Our studies show that a 15% calorie restriction initiated at 4 months of age enhances hypoglycemia-stimulated glucagon secretion ($P < .01$) and decreases basal serum glucagon ($P < .01$), while having no effect on glucagon receptor expression at the liver in 26-month-old mice. Consistent with enhanced hepatic glucagon sensitivity, CR increases glucagon-stimulated hepatic cyclic AMP production ($P < .05$). Glucagon is a primary regulator of AMPK activation and FGF21 release, both of which have been proposed as key molecules to account for CR-induced benefits to aging. CR increases both hepatic AMPK activation ($P < .05$) and FGF21 mRNA expression ($P < .05$). Additionally, CR reduces hepatic lipid accumulation ($P < .05$), and decreases fasting respiratory quotient ($P < .001$), indicating an increase in lipid oxidation. Our studies demonstrate that a moderate (15%) CR regimen enhances glucagon sensitivity and decreases hepatic lipid accumulation in aged mice. Thus, we propose glucagon signaling as a mediator of CR-induced improvements in aging.

REDUCED MUSCLE OXIDATIVE CAPACITY DURING AND AFTER EXERCISE IN OLDER ADULTS WITH OBESITY

Fei Zhao,¹ Anirban Dutta,¹ and Machiko Tomita,² *1. State University of New York at Buffalo, Buffalo, New York, United States, 2. University at Buffalo, State University of New York, Buffalo, New York, United States*

Objective: Obesity and physical activity are two major factors affecting aerobic performance in older adults. The underlying mechanisms of the causes are still unknown. Oxidative capacity, muscles' maximal capacity to utilize oxygen, is a part of aerobic performance. Muscle oxygen level (SmO₂), a measure of oxidative capacity, reflects the balance between oxygen delivery and oxygen demand. When oxygen delivery surpasses oxygen demand, SmO₂ increases, which indicates higher oxidative capacity. This study aimed to identify the influence of obesity and physical activity level on SmO₂ changes during and after short exercise. Methods: This is a cross-sectional study. SmO₂ changes during and after a bilateral heel-raise (BHR) test were measured in 60

community-dwelling older adults (≥ 60 years old) in four groups: inactive obese, active obese, inactive non-obese, and active non-obese. Inactive is defined as performing less than 150 minutes/week moderate-intensity activity. Results: The inactive obese group took a longer time for SmO₂ drop during the BHR test, had a lower SmO₂ level at the end, and recovered slower after the test than all other groups. Especially, compared with the active non-obese group, this group exhibited significantly poorer SmO₂ recovery one minute after the test, 5.3% less ($p=.036$). The active obese group's oxidative capacity was similar to the inactive non-obese group, although lower than the active non-obese group. Discussion: To prevent physical decline in older adults with obesity, regular exercise has been recommended. This study substantiated this from a hemodynamics viewpoint. Older adults with obesity need 150+ minutes/week moderate-intensity exercise.

REDUCING METHYLGLYOXAL RESCUES OBESITY RELATED PHENOTYPES AND LIFESPAN IN A LEPTIN RECEPTOR DEFICIENT MOUSE MODEL

Lauren Wimer,¹ Martin Valdearcos Contreras,² Muniesh Muthaiyan Shanmugam,¹ Jessica Ramirez,¹ Jennifer Beck,¹ Suneil Koliwad,³ and Pankaj Kapahi,¹ *1. UCSF Diabetes Center, 94143, California, United States*

Obesity remains one of the leading risk factors for aging and age-related diseases such as Alzheimer's and type II diabetes, and affects 40% of the US population. The occurrence of obesity has been closely tied to an increase in sugar consumption with chronic hyperglycemia enhancing glycolysis. One of the byproducts of glycolysis is methylglyoxal (MGO), a reactive precursor for advanced glycation end-products (AGEs), which drives type II diabetes and its complications. We hypothesize that an MGO-derived AGE, MG-H1, affects hypothalamic regulation of food consumption and metabolism parallel to the leptin pathway in mice fed a high carbohydrate diet. Exogenous supplementation of MG-H1 increased food consumption rates and weight gain. Conversely, glycation byproduct lowering compounds (GLY-LOW), a customized chemical cocktail that blocks the production of MGO, rescued over-feeding phenotypes in wild-type mice. Furthermore, GLY-LOW treatment in a leptin receptor deficient mouse model rescued weight gain, diabetic phenotypes and lifespan. RNA sequencing of the hypothalamus of leptin receptor deficient mice treated with GLY-LOW showed significant downregulation of Rax, a gene responsible for tanyocyte differentiation, and several genes involved in feeding and aging. We propose that specific cells in the hypothalamus both make and respond to MG-H1. We will also discuss evidence for the potential of GLY-LOW as a new class of therapeutics that reduce the effects of glycation to reduce food intake and slow aging.

TARGETING CELLULAR SENESCENCE WITH NOVEL SENOTHERAPEUTICS BY DESIGN TO EXTEND HEALTHSPAN

Lei Zhang,¹ Brian Hughes,² Luise Angelini,² Ryan O'Kelly,² Matthew Yousefzadeh,² Ted Kamenecka,³ Laura Niedernhofer,² and Paul Robbins,² *1. University*

of Minnesota, Saint Paul, Minnesota, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States, 3. Scripps Florida, Scripps Florida, Florida, United States

Senescent cells accumulate with age in various tissues and organs, leading to the decline in tissue function and deterioration of many age-related diseases and aging. Senolytics have emerged as an effective therapeutic approach to eliminate senescent cells to improve aging phenotypes and associated co-morbidities. Despite their promising potential, only a handful of senolytics have been reported, including a natural flavonoid fisetin discovered by our group. Fisetin has been shown to reduce senescence, suppress age-related pathology, and extend healthspan in aged mice. However, its moderate potency, potential mutagenic risk and poor bioavailability have limited its further clinical applications. By leveraging drug design, medicinal chemistry and high-content imaging analysis, we have successfully optimized the senolytic activity of fisetin, leading to the identification of two improved fisetin senolytic analogs (FAs) with reduced toxicity in non-senescent cells. The improved senolytic activity of these FAs was demonstrated in murine and human senescent cell models as well as in accelerated aging and naturally aged mouse models. The analysis of the senolytic activity of the FAs as well as several other recently identified senolytics, including a senolytic lipid, will be presented.

TARGETING KYNURENINE METABOLISM TO REDUCE INFLAMMATION AND ENHANCE STRESS RESPONSE DURING AGING

George Sutphin,¹ Hope Dang,² Luis Espejo,³ Raul Castro-Portuguez,¹ Bradford Hull,⁴ Jeremy Meyers,² Emily Turner,² and Destiny DeNicola,¹ 1. *The University of Arizona, Tucson, Arizona, United States*, 2. *University of Arizona, Tucson, Arizona, United States*, 3. *UNIVERSITY OF ARIZONA, TUCSON, Arizona, United States*, 4. *University of Arizona, Arizona, United States*

Aberrant kynurenine pathway metabolism is increasingly linked to aging and age-associated disease. Kynurenine metabolic activity increases with age and becomes dysregulated during various forms of age-associated pathology in humans. By manipulating one or more kynurenine pathway enzymes and metabolites, we have extended lifespan up to 40% in *Caenorhabditis elegans*. In particular, elevating physiological levels of the kynurenine pathway metabolite 3-hydroxyanthranilic acid (3HAA) by directly supplementing 3HAA or inhibiting the enzyme 3HAA dioxygenase (HAAO) extends *C. elegans* lifespan by ~30%. 3HAA delivered chronically in chow similarly extends lifespan in aged C57BL/6 mice. In ongoing work, we are investigating the mechanisms underlying the benefits of multiple kynurenine pathway interventions using tools in *C. elegans*, mice, and human cell culture. We have preliminary evidence for activation of broad-spectrum cellular stress response, enhanced immune function, and reduced inflammation. Among other roles, the kynurenine pathway is the sole metabolic route for de novo synthesis of nicotinamide adenine dinucleotide (NAD⁺) from tryptophan in Eukaryotic cells. We are examining the regulatory interaction between kynurenine metabolism and the two NAD⁺ recycling pathways, Salvage and Preiss-Handler, both as potential mechanistic mediators and

as possible parallel targets for combined interventions with synergistic benefits in aging. We are further evaluating the impact of these interventions in several models of specific age-associated diseases, including sepsis, chronic inflammation, stroke, Alzheimer's disease, and cancer. Finally, we are developing pharmaceutical strategies to replicate key genetic and metabolic interventions within the kynurenine pathway that can be readily translated into clinical applications.

THE INTERACTION OF OSMOTIC AND HEAVY METAL STRESS IN *C. ELEGANS*

Emily Turner,¹ Amanda Furtmann,¹ Hope Dang,¹ Destiny DeNicola,² and George Sutphin,² 1. *University of Arizona, Tucson, Arizona, United States*, 2. *The University of Arizona, Tucson, Arizona, United States*

Cellular stress is an ever-present aspect of aging and a primary driver of many common age-associated diseases such as cancer, diabetes, or neurodegenerative diseases. As we age, stress-induced damage accumulates over time, along with reduced efficacy of stress response pathways at combating such damage. Molecular stress response pathways are well studied in the context of individual stressors, but there is a lack of understanding of how these responses change when multiple stressors are encountered at the same time. The goal of our work is to explore the impact of multiple simultaneous stressors on health and survival, and to investigate the underlying molecular pathways involved. To accomplish this, we utilize the nematode *Caenorhabditis elegans* to monitor lifespan changes in response to various stressors. We simultaneously exposed *C. elegans* to high concentrations of sodium chloride and cadmium chloride, known to induce osmotic and heavy metal stress, respectively. We found that lifespan is drastically decreased by the combined stress, significantly more so than the reduction in lifespan caused by either individual stress. Our results show that glycerol levels, which are normally increased in response to osmotic stress, are significantly lowered when the two stresses are combined compared to levels detected for osmotic stress alone. This suggests that the presence of cadmium may sensitize worms to sodium and other osmotic stressors by blunting cells' ability to mount an appropriate molecular response. In ongoing work, we will continue to dissect the mechanisms through which cadmium influences glycerol production and other aspects of osmotic stress response.

THE PROTECTIVE EFFECTS OF APIGENIN ON COGNITIVE FUNCTION AND THE BRAIN TRANSCRIPTOME IN OLD MICE

Alyssa Cavalier,¹ Zachary Clayton,² David Hutton,² Cali McEntee,¹ Douglas Seals,² and Thomas LaRocca,¹ 1. *Colorado State University, Fort Collins, Colorado, United States*, 2. *University of Colorado Boulder, Boulder, Colorado, United States*

Age-related declines in cognitive function increase the risk of developing mild cognitive impairment and dementia, but select nutraceuticals (bioactive plant compounds) may hold promise for protecting the brain and improving cognitive function with age. Apigenin is a flavonoid nutraceutical found in chamomile and reported to inhibit multiple hallmarks of aging; however, it has not been studied in the context of brain aging specifically. We treated young (6 mo)

and old (27 mo) C57BL/6N mice with apigenin (0.5 mg/mL in 0.2% carboxymethylcellulose) or control (0.2% carboxymethylcellulose) drinking water for 6 weeks. Then, we assessed cognitive function and performed RNA-seq to characterize global transcriptomic changes and potential mechanisms of action in the brain. We observed impaired novel object recognition (NOR) test performance (an index of learning/memory) in old vs. young control mice ($P < 0.0001$), but old apigenin mice had ~3-fold higher NOR performance relative to old control mice ($P = 0.02$). Transcriptomic analyses also showed age-associated gene expression changes related to immune function and inflammation, consistent with the established role of inflammation in brain aging. However, some of these key changes were reversed by apigenin. In fact, >300 genes were differentially expressed in old apigenin-treated mice vs. old controls, and the biological processes linked with these differences were related to innate and adaptive immune function, and cytokine and chemokine regulation. We are performing protein/signaling pathway analyses to elucidate downstream cellular changes associated with apigenin treatment, but our current results suggest apigenin may be a promising nutraceutical candidate for preventing brain aging.

THE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY INTENSITY AND VOLUME ON PROSPECTIVE FALLS IN OLDER ADULTS

Justin Whitten,¹ Dawn Tarabochia,² David MacDonald,³ Rod Barrett,³ Chris Carty,³ and David Graham,² 1. *Montana State University, BOZEMAN, Montana, United States*, 2. *Montana State University, Bozeman, Montana, United States*, 3. *Griffith University, Gold Coast, Queensland, Australia*

The benefits of Physical Activity (PA) for older adults have been well documented relative to several physiological and neuromuscular factors, but the direct relationship of PA to fall incidence is unclear. In particular, the influence of the intensity and volume of habitual activities of daily living is poorly understood. The purpose of this study was to evaluate the influence of general PA intensity and overall volume on prospective falls in older adults. The PA of 134 participants was recorded using accelerometers (ActiGraph-GT3X+) over 7 consecutive days. Intensity was classified as light, moderate and vigorous by step frequency. The activity of all participants was graded as sedentary to low intensity, no participant exhibited activity in the vigorous category. During the following 12-months, participants maintained a daily falls diary and completed monthly phone calls to monitor fall incidence. Responses were used to categorize participants as fallers or non-fallers. Eighteen participants experienced one or more falls during the 12-month period. There was no statistical difference between fallers and non-fallers in either total step count or the percentage of time spent in sedentary or light PA. While previous reports suggest that many falls occur during light PA, our results do not suggest that greater volumes of low intensity activities alone results in greater fall incidence. However, we suggest this result may be influenced by physical stimuli participants received within the larger overall study design including a session of repeated exposure to forward loss of balance.

TOTAL TRANSCRIPTOME RESPONSES TO LOW AND HIGHER INTENSITY AEROBIC EXERCISE INTERVENTIONS IN OLDER ADULTS

Meghan Smith,¹ Gabriella McWilliams,¹ Angela Bryan,² Douglas Seals,² and Thomas LaRocca,¹ 1. *Colorado State University, Fort Collins, Colorado, United States*, 2. *University of Colorado Boulder, Boulder, Colorado, United States*

Aerobic exercise is a universally recommended strategy for increasing healthspan, and recent advances in next-generation sequencing and bioinformatics (e.g., RNA-seq/transcriptomics) have made it possible to broadly profile the molecular transducers of exercise. However, most transcriptome studies of exercise have focused on coding genes only, and the transcriptomic response to different exercise interventions has not been characterized by RNA-seq in older adults. Therefore, we performed total RNA-seq (to capture both coding and non-coding gene expression) on peripheral blood mononuclear cells collected from healthy, previously sedentary older adults (males and females, aged 70 ± 1 years). Samples were collected before and after 16 weeks of either low-intensity continuous training (LICT, 50% maximum heart rate, 3 x 30 min/week) or moderate-intensity continuous training plus interval training (MICT+IT, 60-80% maximum heart rate, progressively increased to include IT, 3 x 30 min/week). We found that both interventions modified biological processes (transcriptome modules) related to oxygen transport and reduced inflammatory signaling/immune activation processes (more pronounced with LICT). Interestingly, transcriptome changes unique to LICT subjects included increased expression of genes linked with vascularization and endothelial cell migration, whereas MICT+IT was uniquely associated with a robust increase in antioxidant response gene expression. We also observed numerous changes in long non-coding RNAs and microRNAs that could be linked with these exercise-associated gene expression changes with both interventions. These data provide a first comprehensive look into transcriptomic changes associated with moderate vs. low intensity aerobic exercise in older adults, and they suggest distinct benefits of each exercise strategy.

TREADMILL TRAINING IMPROVES AEROBIC CAPACITY IN AGED MALE MICE COMPARED TO VOLUNTARY WHEEL RUNNING

Emily Schmitt, Hunter Graves, and Danielle Bruns, *University of Wyoming, Laramie, Wyoming, United States*

Preclinical exercise studies typically use two forms of exercise training protocols: 1) voluntary wheel running and 2) forced treadmill running. Previous work from our group clearly demonstrates that older (18-month-old) male mice do not voluntarily engage in wheel running, especially compared to younger males or female mice. Therefore, we implemented a forced exercise treadmill training protocol to determine if treadmill training was superior to wheel running in improving aerobic capacity in older male mice. PURPOSE: To determine if a 3-week treadmill training protocol improved time to exhaustion (TTE) in older male mice. METHODS: 18-month-old male mice ($n=5$) were provided a running wheel in their individual cage for 2 weeks or underwent daily treadmill training ($n=6$) for 3 weeks with

increasing speed/incline. At the end of the training period we assessed TTE. RESULTS: Older male mice that trained on the treadmill demonstrated higher TTE compared to wheel (1382 \pm 32 seconds versus 500 \pm 99 seconds, respectively). In addition, older male mice that trained on the treadmill improved on average ~8% in their TTE test. CONCLUSION: A 3-week treadmill training protocol improves aerobic capacity in older male mice to a greater extent than voluntary wheel running. Ongoing experiments will utilize this training protocol to understand age-related declines in cardiorespiratory fitness, circadian rhythm, and to test exercise as an intervention in the aging population.

VALSARTAN AND SACUBITRIL COMBINATION TREATMENT ENHANCES COLLAGEN PRODUCTION IN OLDER ADULT HUMAN SKIN CELLS

Sela Marin,¹ Ines godet,² Lolita S. Nidadavolu,³ Jeremy Walston,³ Daniele Gilkes,⁴ and Peter M. Abadir,³
 1. Johns Hopkins University, Baltimore, Maryland, United States, 2. Johns Hopkins University, 21287, Maryland, United States, 3. Johns Hopkins University School of Medicine, Baltimore, Maryland, United States, 4. Johns Hopkins School of Medicine, Baltimore, Maryland, United States

Collagen is a major component of the skin's support system, allowing for firmness, elasticity, and mechanical strength. In older adults, skin collagen production decreases significantly, and is associated with increased sagging, wrinkling, and thinning. The Renin Angiotensin System (RAS) is a key hormonal system that changes with age and affects multiple organ systems. While primary health benefits of Angiotensin (Ang) receptor type1 (AT1 R) blockers (ARBs) are believed to arise from systemic effects on blood pressure. There exists a skin-specific Renin Angiotensin System (RAS), but the impact of ARBs on older skin is unknown. Human skin fibroblasts from individuals aged 2 (young individual) and 57 (older individual) were treated with drugs that alter RAS: Valsartan (an ARB) and neprilysin inhibitor Sacubitril. Fibroblast proliferation and collagen production was quantified in response to the drug treatment using fluorescence microscopy. Fibroblasts from 57-year-old individuals were slower to proliferate and had less collagen content as compared to fibroblasts from young individual. Valsartan alone treatment had no effect on collagen production from young or old fibroblasts. In contrast, Sacubitril treatment increased collagen production by approximately three-fold in young (2.87 \pm 0.27 RFU, P<.0001), and older (2.93 \pm 0.53 RFU, P<.0001) fibroblasts. Concomitant treatment with Valsartan and Sacubitril increased collagen production by five-fold increase (5.36 \pm 1.08 RFU, P<.0001) in young fibroblasts, and four-fold (4.18 \pm 0.96 RFU, P=.003) in older cells. This study demonstrates a novel use for the widely prescribed drug combination, Sacubitril and Valsartan, which significantly improves collagen production in older adult fibroblasts.

Biology of Aging: Mitochondria

A STUDY OF C2C12 MYOBLAST BIOENERGETICS IN RESPONSE TO THE CCG-1423 RHO A INHIBITOR

Bachkhua Nguyen,¹ Fathima Ameer,² Jasmine Crane,² Gohar Azhar,² Xiaomin Zhang,¹ and Jeanne Wei,²

1. University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States, 2. UAMS, UAMS, Arkansas, United States

CCG-1423 is a Rho A pathway inhibitor which has been reported to inhibit Rho/SRF-mediated transcriptional regulation. SRF and SRF cofactors, which include ternary complex factors (TCFs) and myocardin-related transcription factor (MRTF), regulate various cellular functions. The Rho/SRF signaling pathway also regulates the sirtuin 2 (SIRT2) gene that contains a classic serum response element (SRE) sequence. Current research on CCG-1423 focuses on gene expression levels of SRF in response to CCG-1423 and how SRF levels affect the cells; the studies are focused on cell morphology, migration, viability/reproduction, and overall function. The pathways of this inhibitor have yet to be fully elucidated, but several have been suggested with good evidence. Our goal is to study the effect of CCG-1423 on mitochondrial function and gene expression of cells. In this work C2C12 myoblast cells have been used as an in-vitro model to study cellular bioenergetics and variations in gene expressions induced by CCG-1423. The effect of CCG-1423 on mitochondrial function was determined by measuring the mitochondrial oxygen consumption rate and glycolysis rate after treating C2C12 cells with varying concentrations of CCG-1423 overnight. In C2C12 myoblast cells, CCG-1423 treatment significantly reduced mitochondrial oxygen consumption rate (OCR) in a dose-dependent manner. However, treatment of C2C12 cells with CCG-1423 overnight increased the extracellular acidification rate (ECAR) in a dose-dependent manner. By indicating that CCG-1423 represses mitochondrial respiration via the Rho-SRF signaling pathway, the results of this study may enable a better understanding of the bioenergetics of the cell in the aging body.

DEPLETION OF THE MIR-34A "SPONGE" MALAT1 IN AGING SKELETAL MUSCLE: IMPLICATIONS FOR AGE-RELATED MUSCLE LOSS

Ling Ruan,¹ Bharati Mendhe,¹ Carlos Isales,¹ William Hill,² Meghan McGee-Lawrence,³ Sadanand Fulzele,¹ and Mark Hamrick,¹ 1. Medical College of Georgia, Augusta, Georgia, United States, 2. Medical University of South Carolina, Charleston, South Carolina, United States, 3. Medical College of Georgia, Augusta University, Augusta, Georgia, United States

We have recently shown that increased levels of reactive oxygen species (ROS) in aging skeletal muscle are associated with increased expression of the senescence-associated microRNA miR-34a-5p (miR-34a). The histone deacetylase Sirt1 is a validated target of miR-34a, and miR-34a expression is induced by the tumor suppressor p53 which is itself stimulated by ROS. Long noncoding RNAs (lncRNAs) are known to function as "sponges" for microRNAs, but the role of such competing endogenous RNAs (ceRNA) in muscle aging is not well understood. We therefore examined in skeletal muscles of young (4-6 mos) and aged (22-24) male and female mice the expression of several lncRNAs that are predicted to bind miR-34a-5p in silico and whose predicted binding has been validated experimentally. Results indicate a significant decrease in lncRNA MALAT1 expression with aging. MALAT1 is known to be highly expressed during the later stages of myoblast differentiation and myotube maturation. We therefore treated C2C12 cells

at 48 hrs with hydrogen peroxide (10 μ M) and examined changes in MALAT1 expression. MALAT1 was significantly decreased with H₂O₂ treatment, whereas miR-34a is increased in C2C12 cells after hydrogen peroxide exposure. Age-related muscle atrophy mediated by ROS may therefore result in part from related mechanisms involving miR-34a activity: an increase in miR-34a targeting Sirt1 resulting from p53 activation and an increase in miR-34a bioavailability resulting from a decline in miR-34a “sponging” due to ceRNA MALAT1 depletion. These findings suggest that therapeutic interventions increasing MALAT1 expression in muscle may potentially enhance the preservation of muscle mass with aging.

EFFECTS OF GLYCINE AND N-ACETYL-CYSTEINE ON GLUTATHIONE LEVELS AND MITOCHONDRIAL ENERGY METABOLISM IN HEALTHY AGING

Philipp Gut,¹ Giulia Lizzo,² Eugenia Migliavacca,² Leonidas Karagounis,³ Tim Heise,⁴ and Maximilian Eynatten,³ 1. *Cell Biology, Nestlé Institute of Health Sciences, Nestlé Research, Lausanne, Vaud, Switzerland*, 2. *Nestlé Research, Lausanne, Vaud, Switzerland*, 3. *Nestlé Health Science, Vers-chez-les Blanc, Vaud, Switzerland*, 4. *Profile Institut for Metabolic Research, Neuss, Baden-Württemberg, Germany*

Glutathione is an intracellular antioxidant that neutralizes reactive oxygen species and prevents tissue damage. Dietary supplementation with the glutathione precursors glycine and n-acetylcysteine supports the maintenance of normal glutathione levels in several age-related diseases, but the optimal doses and their efficacy in healthy elderly are not established. We report results from a randomized controlled clinical trial in 114 healthy volunteers (mean age = 65 years) receiving glycine and n-acetylcysteine (GlyNAC) at three different doses for two weeks (1.2g/1.2, 2.4g/2.4g, 3.6g/3.6g of each amino acid). Older subjects showed increased oxidative damage and a lower reduced-to-oxidized glutathione ratio (GSH:GSSG) compared to young subjects, but unchanged total glutathione levels. GlyNAC did not increase levels of circulating glutathione compared to placebo treatment, the primary study endpoint. However, stratification analyses suggest that subjects with high oxidative stress and low glutathione status responded with glutathione generation. We find that unrelated to glutathione status, healthy aging was associated with lower levels of fasting glycine that can be increased towards those observed in young subjects with supplementation. Using preclinical models, we find that tissue glycine depletion is a common feature of healthy aging. Supplementation of old mice with glycine efficiently improved age-related decline of mitochondrial respiratory function in skeletal muscle and prevented a gene program associated with protein catabolism observed in control-treated animals. In conclusion, GlyNAC is safe and well-tolerated and may selectively increase glutathione levels in older subjects with oxidative stress and glutathione demand. Our data further suggest that glycine may support mitochondrial function independently of NAC.

LOSS OF ISCHEMIC TOLERANCE WITH AGE: CAN WE PROTECT AN OLD KIDNEY

Egor Plotnikov 1. *A.N. Belozersky Institute of Physico-Chemical Biology, Lomonosov Moscow State University, Moscow, Moskva, Russia*

The most abundant and vulnerable cohort of patients with acute kidney injury (AKI) is represented by the older people. It is well-known, the kidney tissue undergoes some changes with age, both at the morphological and molecular level. Therefore, when treating AKI in older patients, it is necessary to take into account the morphofunctional features of aging kidney tissue and metabolic alterations. We have shown that the kidney of old rats does not perceive signals from the most well-known protective approaches such as ischemic preconditioning (IPC) and caloric restriction (CR). Although the old kidney did not develop more severe AKI after ischemia, we found no pronounced effect on attempts to increase its resistance by IPC and CR. Analysis of the mechanisms underlying this loss of tolerance has shown that the most affected pathways are the mechanism of mitochondrial quality control, the effectiveness of autophagy, and the proliferative potential of kidney cells. However, several protective pathways activated in the young kidney were also active in the old one in response to the CR. In particular, an increase in SIRT1 deacetylase, antiapoptotic Bcl-xL, and a decrease in oxidative stress were observed. Our results show that some defense systems demonstrating their effectiveness in young organisms lose their beneficial effect in old organisms, while others still can be activated by protective approaches. Thus, it is necessary to carefully analyze the possibilities of increasing ischemic tolerance for old organisms. This work was supported by the Russian science foundation (grant #21-75-30009).

METFORMIN PRESERVES MITOCHONDRIAL INTEGRITY AT OLD AGE IN MALE RATS.

Jonathan Wanagat,¹ Allen Herbst,² Austin Hoang,¹ Chiye Kim,³ Judd Aiken,⁴ Debbie McKenzie,³ and Deena Goldwater,¹ 1. *UCLA, Los Angeles, California, United States*, 2. *University of Alberta, Edmonton, Alberta, Canada*, 3. *University of Alberta, University of Alberta, Alberta, Canada*, 4. *UofA, Edmonton, Alberta, Canada*

Metformin is being deployed in clinical trials to ameliorate aging in older humans who do not have diabetes. In *C. elegans*, metformin treatment at old ages exacerbated mitochondrial dysfunction, led to respiratory failure, and shortened lifespan. Metformin is a commonly used, well-tolerated treatment for diabetes in older adults. Mitochondrial effects of metformin treatment in aged mammals has not been sufficiently investigated. We hypothesized that metformin treatment would not be toxic to older mammals. To define a therapeutic dose in aged hybrid rats, we evaluated two doses of metformin (0.1%, 0.75% of the diet) at 30-months of age. Body mass decreased at the 0.75% dose. Neither dose affected mortality between 30- and 34-months of age. We assessed mitochondrial quality, quantity, and function in aged rats treated with metformin at the 0.75% dose by measuring mitochondrial DNA copy number, deletion mutation frequency, and respirometry in skeletal muscle and heart. In skeletal muscle, we observed no effect of metformin on quadriceps mass, mtDNA copy number or deletion frequency. In the heart, metformin treated rats had higher mtDNA copy number, lower cardiac mass and no effect on deletion frequency. Metformin treatment resulted in lower mitochondrial complex I activity in both heart and quadriceps. Metformin did not compromise mitochondrial integrity, was well tolerated, and may have cardiac benefits to rats at old ages.

SUCCESSFUL EXOGENOUS EXPRESSION OF ATP8, A MITOCHONDRIAL ENCODED PROTEIN, FROM THE NUCLEUS IN VIVO.

David Begelman,¹ Bhavna Dixit,² Caitlin Lewis,² Mark Watson,³ Martin Brand,³ and Amutha Boominathan,²
 1. SENS Research Foundation Research Center, Novato, California, United States, 2. SENS Research Foundation Research Center, Mountain View, California, United States, 3. Buck Institute for Research on Aging, Novato, California, United States

Replicative errors, inefficient repair, and proximity to reactive oxygen species production sites make the mitochondrial DNA (mtDNA) susceptible to damage with time. mtDNA mutations accumulate with age and accompany a progressive decline in organelle function. We lack molecular biology tools to manipulate mtDNA, thus we explore the possibility in vivo of utilizing allotopic expression, or the re-engineering mitochondrial genes and expressing them from the nucleus, as an approach to rescue defects arising from mtDNA mutations. This study uses a mouse model with a mutation in the mitochondrial ATP8 gene that encodes a protein subunit of the ATP synthase. We generated a transgenic mouse with an epitope-tagged recoded and mitochondrial-targeted ATP8 gene expressed from the nucleus. Our results show that the allotopically expressed ATP8 protein in the transgenic mice is robustly expressed across all tested tissues, successfully transported into the mitochondria, and incorporated into ATP synthase. We are currently evaluating if allotopic expression of ATP8 will functionally rescue the behavioral and bioenergetic defects in ATP8 mutant mice. Translating allotopic expression technology into a mammal and demonstrating systemic functional rescue will lend credence to utilizing allotopic expression as a gene therapy in humans to repair physiological consequences of mtDNA defects that may accumulate with age.

Session 9115 (Poster)

Cancer and Aging

EXPLORING SPIRITUALITY, LONELINESS AND HRQOL IN HISPANIC CANCER CAREGIVERS

Jennifer King,¹ Terry Badger,² Chris Segrin,² and Cynthia Thomson,³ 1. University of Arizona Cancer Center, Marana, Arizona, United States, 2. University of Arizona, Tucson, Arizona, United States, 3. University of Arizona, Mel and Enid Zuckerman College of Public Health, Tucson, Arizona, United States

Providing care to an aging society in the new normal requires increased attention to the informal caregivers who support the health and well-being of older adults with chronic conditions. Hispanic caregivers carry a high caregiver-associated burden. Health disparities experienced by Hispanics, coupled with the emotional, social and physical demands of caregiving, may set an unprecedented risk for lower health-related quality of life (HRQoL). In a quantitative analysis, we investigated the relationship between spirituality, loneliness and HRQoL in Hispanic cancer caregivers using baseline data from the Support for Latinas with Breast Cancer study (N= 234 Hispanic caregivers). Findings

suggested an indirect effect of spirituality on HRQoL through reduced loneliness among more spiritual caregivers, effects that were independent of age. The second study was conducted using qualitative semi-structured interviews (N= 10) with Hispanic caregivers. Interviews evaluated spirituality and HRQoL in Hispanic cancer caregivers who reported variable levels of loneliness. Five themes emerged: caregiver experience, coping strategies, loneliness, religion to gain strength or support, and spirituality to gain strength or support. Results supported the role of spirituality in promoting higher HRQoL in Hispanic cancer caregivers and elucidated pathways to intervene on HRQoL through spirituality. With Hispanics often underutilizing formal services, having an improved understanding of caregiving experiences, particularly related to spirituality, will support the development of culturally-relevant strategies and programming to promote HRQoL for Hispanic caregivers.

GERIATRIC ONCOLOGY: COGNITION AND COMMUNICATION

Patricia Parker,¹ Yesne Alici,² Christian Nelson,² Smita Banerjee,³ Charlotte Mallng,² Nessa Coyle,² and Beatriz Korc-Grodzicki,⁴ 1. Memorial Sloan Kettering Cancer Center, Memorial Sloan Kettering Cancer Center, NYC, New York, United States, 2. Memorial Sloan Kettering Cancer Center, New York, New York, United States, 3. Memorial Sloan Kettering Cancer Center, Memorial Sloan Kettering Cancer Center/New York, New York, United States, 4. Memorial Sloan Kettering Cancer Center, Memorial Sloan Kettering Cancer Center, New York, United States

With the dramatic increase in the older adult population, assessment and care of chronic diseases of aging, notably cancer, cognitive impairment and functional decline, have increasing clinical importance. Most healthcare practitioners (HCPs) receive minimal education in geriatrics and/or communication skills and are not optimally prepared to treat older cancer patients. Geriatric Oncology: Cognition and Communication (Geri-Onc CC) trains HCPs to identify cognitive impairment and/or functional decline and improve communication with patients and caregivers. Geri-Onc CC is a 2-day virtual training. Day 1 covers depression, dementia, delirium, pharmacology, cognitive rehabilitation, language barriers, and decision-making capacity. Day 2 focuses on communication skills experiential practice in geriatric syndromes, cognitive syndromes and shared decision making. In addition, HCPs engage in 6 bimonthly web-based collaborative learning activities post-training. Thus far, three cohorts have participated (n=56). Participants were primarily female (88%), 68% non-Hispanic White, and represented multiple disciplines [psychologists (29%) social workers (25%), physicians (21%), others(25%)] and they work in various settings: comprehensive cancer centers (43%), community hospitals (18%), and others (33%). Most (48%) have been caring for older cancer patients for 1-5 years. All reported the training had value to them as a clinician, increased their knowledge of geriatrics, and helped them meet their training goals and 84% were extremely satisfied with the program. Recruitment has been successful. Participants have been diverse in terms of race/ethnicity, profession, practice characteristics and the populations they serve. Overall, participants

have found the training valuable, future work will describe outcomes of the training.

MEMORY AGING PHENOTYPES AMONG OLDER CANCER SURVIVORS: A LATENT GROWTH ANALYSIS OF THE HEALTH AND RETIREMENT STUDY

Ashly Westrick, Kenneth Langa, and Lindsay Kobayashi, *University of Michigan, Ann Arbor, Michigan, United States*

While cancer survivors experience many long-term health effects, there is limited evidence on the potentially heterogeneous memory aging of older cancer survivors. We identified memory aging phenotypes of older US cancer survivors, and determined sociodemographic and health-related predictors of membership. Data were from 2,755 survivors aged ≥ 50 in the U.S. Health and Retirement Study (1998 – 2016). Self-reported first incident cancer diagnosis (except non-melanoma skin cancer) and memory (composite immediate and delayed word-list recall score, combined with proxy-reported cognition) were assessed at biennial interviews. Memory aging phenotypes were identified using latent growth curve (LGC) models, with baseline being time of cancer diagnosis. Logistic regression evaluated predictors of group membership. 5 distinct memory aging groups were identified: low memory ($n=165$, 6.16%); medium-low memory ($n=459$, 17.1%); medium-high memory ($n=733$, 27.4%); high memory ($n=750$, 28.0%); and very high memory ($n=571$, 21.3%). The low memory group received less chemotherapy compared to the other groups (20.0% vs. 25.5%, 31.7%, 36.8%, 41.5%, respectively), and had the shortest mean survival time after diagnosis (1.08 vs 2.10, 2.76, 3.37, 4.31 years, respectively). Older age at diagnosis (OR: 1.71, 95%CI: 1.61-1.82), being male (OR: 4.10, 95%CI: 2.82-6.51), having a history of stroke (OR: 4.62, 95%CI: 2.57-8.30) and depression prior to diagnosis (OR: 1.19, 95%CI: 1.05-1.34) were independently associated with being in the low memory group vs. the medium-high memory group. We identified distinct memory aging phenotypes among older cancer survivors. Further research should evaluate the influence of pre-cancer memory and how these phenotypes differ from the general population.

OLDER BREAST CANCER SURVIVORS' COGNITIVE RESPONSE TO QIGONG/TAI CHI EASY: AN EXPLORATORY ANALYSIS

Dara James, Linda Larkey, and SeungYong Han, *Arizona State University, Phoenix, Arizona, United States*

Increasing rates of breast cancer coupled with improvements in treatment means the number of breast cancer survivors (BCSs) is growing. BCSs frequently report persistent cognitive deficits (i.e., “cancer-related cognitive impairment”) that impacts QOL and treatment compliance. Older (≥ 65 years old) BCSs are more likely to experience cognitive decline and impairment, partly due to the biological process of senescence. In the context of a larger RCT of BCSs (ages 45-75; stages 0-III), we evaluated cognitive function/performance effects on among the older participants (ages 65-75) of 8-weeks Qigong/Tai Chi Easy (QG/TCE) compared to education control (EdC). Cognitive function was measured using the Functional Assessment of Cancer Therapy-Cognitive Function (FACT-COG), including: perceived

cognitive impairment (PCI), and perceptions of effects of cognitive function on quality of life (PCQOL). Cognitive performance was measured using the Wechsler Adult Intelligence Scale-Third Edition (WAIS-III): Digit Span (DS) and Letter-Number Sequencing (LNS). A multilevel model with random intercept was used to examine Group \times Time interactions: The majority of participants ($N= 32$) (M age= 69.7) were white (84%). Changes in WAIS-III DS, LNS and FACT-COG PCI were not statistically significant, but effect sizes were small to medium. The interaction between group and time was significant for FACT-COG PCQOL ($p= 0.033$) with a medium effect size, 0.14. Findings from this exploratory analysis of the larger study suggests that older BCSs' participation in QG/TCE may improve perceptions of effects of cognitive function on quality of life. Such improvements may increase cognitive-related self-efficacy, overall QOL and treatment compliance among older BCSs.

PREDICTORS OF RACIAL DIFFERENCES IN DEPRESSION AND AFFECT AMONG OLDER ADULT, LONG-TERM CANCER SURVIVORS

Gary Deimling,¹ Dyanna Burnham,² and Gabrielle Beck,² 1. *Case Western Reserve University, Cleveland, Ohio, United States*, 2. *Case Western Reserve University, CLeveland, Ohio, United States*

Research has long documented the psycho-social sequelae experienced by those who have been treated for and survived cancer. Depression, affect and other indicators of mood state have been an important focus of that research. However, there is little research on racial differences in depression and affect outcomes or the specific cancer and age-related factors that predict them. The research to be presented is based on a 10 year, six wave NCI funded study of 471 older adult (age 60+), long-term cancer survivors randomly selected from the tumor registry of a comprehensive cancer treatment center. Key outcome measures were depression (CES-D) scale) and both positive and negative affect (PANAS). Covariance analyses and nested OLS Regression were used to identify Black-white differences these outcomes and the relative importance of both cancer and non-cancer predictors. Blacks reported lower levels of depression and negative affect when compared to whites. In a separate regression analysis of the black sub-sample, continuing cancer-related symptoms were by far the strongest predictors ($\beta = .16$) of negative affect. In the white sub-sample, while cancer-related symptoms continued to be a significant predictor ($\beta = .16$), non-cancer symptoms were substantially more important ($\beta = .22$). These results will hopefully help practitioners to have a better understanding of the nuanced racialized experiences and mental health among cancer survivors, and how these may impact after-care for older adult cancer survivors.

SHAKEN IDENTITIES, RESERVE MASCULINE CAPITAL, AND THE LIVED EXPERIENCES OF AGING MEN WITH BREAST CANCER

Edward Thompson,¹ and Renee Beard,² 1. *College of the Holy Cross, Broadview Heights, Ohio, United States*, 2. *College of the Holy Cross, College of the Holy Cross, Massachusetts, United States*

A question that begs to be examined is: How does aging men's discovery they have breasts as a result of their breast

cancer diagnosis and having a breast removed through a mastectomy, affect their masculine subjectivities and practices, as they also go about also living with a life-threatening illness? The present study aimed to better understand how men come to live with the knowledge that they have both breasts and cancer. Interviews with seventeen men in the U.S. (mean age 62.8) with a breast cancer diagnosis, mastectomy, and, most often, post-surgical hormonal treatment uncovered stories of body-self disruption and identity dilemmas. All the men's identities had been shaken. After their mastectomy, they were reminded every morning that the body reflected in the mirror differed significantly from who they once were. Their stories revealed strategic themes: how they lived with cancer by slightly modifying conventional masculinities; and how others interacted with them, with the exception of mammography technologists, in terms of their gender, not their atypical illness. Only a few men initially felt their breast cancer was a gendered stigma. Noticeable was how the historical era when diagnosed and the age of the man at diagnosis contextualized their illness stories. In this presentation, three cases are used to exemplify the men's varied experiences with their non-normative bodies and their commonality in finding reserves of masculine capital to rebuke the existential loneliness of a man with breast cancer.

TECHNOLOGY USE AMONG CANCER PATIENTS PRE- AND POST- COVID-19 PANDEMIC: THE ROLE OF DEMENTIA

Weixin Li,¹ Katherine Ornstein,² Yan Li,³ and Bian Liu,² 1. *Icahn school of Medicine at Mount Sinai, Long island city, New York, United States*, 2. *Icahn School of Medicine at Mount Sinai, New York, New York, United States*, 3. *Icahn School of Medicine at Mount Sinai, Icahn School of Medicine at Mount Sinai, New York, United States*

COVID-19 has highlighted increasing reliance on information and communication technology (ICT) and challenges in access and use. ICT access also provides resources that benefit users' mental health. Our study describes changes in the use of ICT before and during the COVID-19 pandemic among cancer patients with and without dementia. We identified 196 (1.6 million weighted population) older adults with a self-reported cancer history who participated in both 2019 and 2020 National Health and Aging Trends Study (NHATS). In 2019, cancer patients with dementia (9.9%) were less likely (adjusted OR 0.29; 95%CI, 0.11-0.78) to use information technology (IT) for health matters (contacting medical providers, handling health insurance matters, obtaining information about health conditions, and ordering prescription refills) compared to those without dementia. In contrast, dementia status was not associated with communication technology (CT) use (email or texts) or IT use for personal tasks (grocery shopping or online banking). IT use for personal tasks was inversely associated with anxiety symptoms (adjusted OR 0.22; 95%CI:0.06-0.83) and CT use was inversely associated with depressive symptoms (adjusted OR 0.25 (95%CI:0.07-0.97)). In 2020, regardless of dementia status, all cancer patients increased their virtual (email/phone/video) contact with family, friends (3.4%-7.0%), and medical providers (17.2%-36.2%) while decreasing in-person contact (10.0%-15.7% and 21.8%-24.2%, respectively) during the pandemic. This study suggests that there are potential unmet

daily needs for patients with comorbid cancer and dementia that may be met with improved ICT access. Such challenges are of increasing concern as COVID-19 has resulted in increased ICT reliance for older adults.

Session 9120 (Poster)

Chronic Disease Management (BSS Poster)

A QUALITATIVE INQUIRY ON SELF-MANAGEMENT DECISION MAKING AMONG RURAL AFRICAN AMERICANS WITH TYPE 2 DIABETES

Idethia Shevon Harvey, *University of Missouri, Columbia, Missouri, United States*

Living in a rural area has been recognized as a unique health disparity associated with higher rates of chronic disease. It is further compounded for those who are the most structurally vulnerable complicating access to care and negatively affecting health outcomes. Barriers to type 2 diabetes (T2DM) self-management remain a growing concern, particularly among minority communities living in underserved geographical areas. Much of the self-management research focused on compliance with medication regimens and modification of lifestyle choices. A less well-understood but arguably more critical aspect is the social factors in disease management decision-making. Purposive sampling was used to identify rural African Americans (n = 34). The mean age of participants was 65.9 years (SD = 12.3), and T2DM diagnosis was 15 years (SD = 12.4). The study utilized the consensual qualitative research methodology and the "Sort and Sift, Think and Shift" approach to identify themes. The participants reported an alternative way of integrating glucose monitoring through a "feedback loop" of body sensing. The longer they live with the condition (i.e., knowing my body), the more they can interpret whether they are hypoglycemic or hyperglycemic (i.e., deciphering the cues) to create and navigate their disease management strategy (i.e., body sensing). Self-management decision-making is a complex developmental process that includes disease trajectory and cultural and environmental factors. Findings from this study may provide a conceptual framework for ongoing inquiry and may provide insights to help T2DM educators and clinicians fully understand the complexity of long-term disease management among rural African Americans.

FALL DETECTION: USING TECHNOLOGY TO PREVENT FALLS AND SAVE LIVES

Lydia Manning, *Dele Health Tech, United States*

Companies, providers, and consumers alike are increasing the use of technology in almost every industry. This increase in usage occurs simultaneously in a technology marketplace characterized by rapid evolution in design and products. Recent years have witnessed the surge of various technological products and solutions in the age-tech marketplace, particularly in senior living and many related to fall detection and prevention interventions. Falls can have a widespread and significant impact on health, can be deadly, and often result in high costs for individuals and older adult living facilities. One out of four older adults fall each year. Findings from a pilot project illustrate the total incident count for a

12-month period. Findings demonstrate the importance of having a complete solution for falls and a fall detection solution in place in an assisted living environment. Ideal environments for residents, families, staff, and those working in the facility with regard to smart tech are considered. It is important to consider how can these solutions empower residents and afford people autonomy and safety through dignified technology.

RISK PERCEPTION AND COMMUNAL COPING IN FAMILIES AFFECTED BY TYPE 2 DIABETES

Jielu Lin,¹ Melissa Zajdel,¹ Melanie Myers,² and Laura Koehly,¹ 1. *National Institutes of Health, Bethesda, Maryland, United States*, 2. *Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio, United States*

Despite a recent decline, rates of type 2 diabetes remain high among older adults. Preventing and delaying the onset of the condition with lifestyle changes is key to reducing disease burden in the population. Type 2 diabetes is a complex disease, likely a result from the joint effect of genetic, socio-environmental and lifestyle risk factors that are clustered in families. As such, the prevention of type 2 diabetes is a communal coping process, where individuals communicate about risk and establish routines to facilitate one another's health habits and compliance with therapeutics. This poster investigates how such a process is affected by one's perception of risk based on his/her knowledge about family health history (FHH). We collected family network data from families of different racial backgrounds in the greater Cincinnati area (28 white and 17 black/ African American households; 127 participants). The analysis focuses on how the density of diabetes diagnosis in one's FHH affects communication about shared risk for type 2 diabetes and encouragement to maintain or adopt a healthy lifestyle. Results suggest a higher concentration of diabetes diagnosis in one's FHH is associated with a higher number of risk communication ties in all families. With regards to encouragement ties, high rates of diabetes diagnosis in FHH are associated with an increased number of encouragement ties only in families of black/African heritage. The findings highlight the need and promise of using FHH to motivate co-encouragement to maintain/adopt a healthier lifestyle in families of black/African heritage.

THE EVALUATION OF SMART SPEAKER SKILLS FOR CHRONIC DISEASE MANAGEMENT OF OLDER ADULTS

Melissa Pighin,¹ and Yong Kyung Choi,² 1. *University of California, Davis, Sacramento, California, United States*, 2. *University of California Davis School of Medicine, Sacramento, California, United States*

A voice-activated smart speaker is an emerging technology that presents unique opportunities to support the chronic disease management of older adults. We identified the available health-related smart speaker skills in Amazon Alexa platform that support chronic disease management and assessed their functionalities to inform the development of a home-based lifestyle intervention program for older adults with cardiovascular disease and type 2 diabetes. From January to March 2021, we searched Alexa Skills using keywords related to diabetes, medication, blood pressure and nutrition management. Our search produced total 156

potentially relevant skills (63 diabetes, 57 medication, 11 blood pressure and 25 nutrition related), of which 22 skills met inclusion criteria. Apps were excluded if it was only informational, not relevant to the topic, had zero user rating, available in language other than English, and required an external device or a subscription to a specific health plan or service. 22 skills (4 diabetes, 8 medication, 3 blood pressure and 7 nutrition) were evaluated with Echo Show 8 device. The skills were evaluated using the modified version of IMS Institute for Healthcare Informatics app functionality scores and the score (0 to 11) was calculated accordingly. The median number of functionalities was 3.5 and 68% of skills (15/22) had 4 or fewer functions. The highest rated skill was a medication management app named myNurseBot having 6 out of 11 functionalities. The poor functionality score highlights a need for a more robust and comprehensive smart speaker skill to support the health management of older adults.

Session 9125 (Poster)

Civic Engagement and Voluntarism

CIVIC ENGAGEMENT IN RETIREMENT AND THE SOCIOEMOTIONAL EXPERIENCE OF PANDEMIC TIME

Boroka Bo, *University of California, Berkeley, Berkeley, California, United States*

This research integrates literature from the sociology of the life course, sociology of emotions and the sociology of time to examine how Socioeconomic Status (SES) influenced retiree civic engagement during the COVID-19 pandemic. I find that SES framed both the social experience of time and the prevalent emotions experienced by retirees while physically distancing during the early days of the pandemic. These individual-level experiences translated to markedly different blueprints for civic engagement. High-SES retirees were more likely to 'go global', organizing to advocate for their interests. Conversely, low-SES retirees were more likely to 'turn in', minimizing their civic engagement. My findings reveal how existing sociopolitical inequalities may become further entrenched in public health crises. Policies aimed at combating inequalities in later life also need to consider socioemotional and sociotemporal factors.

INTERNALIZED AGE STEREOTYPES AS A MEDIATOR BETWEEN VOLUNTEERING AND PSYCHOSOCIAL HEALTH FOR ADULTS 50+

Andrew Steward,¹ Leslie Hasche,² and Julie Anne Laser-Maira,² 1. *University of Denver, Lone Tree, Colorado, United States*, 2. *University of Denver, Denver, Colorado, United States*

The productive aging literature describes a wide range of psychosocial benefits of volunteerism for older adults. A growing, compelling body of literature drawing from stereotype embodiment theory identifies significant, negative public health impacts of internalized age stereotypes. Yet, little research has explored which activities may reduce internalized ageism and enhance psychosocial health as people age. This cross-sectional study examined whether internalized age stereotypes mediate the relationship between

volunteering and social connectedness for adults 50+. A convenience sample of volunteers ($n = 112$) 50+ years of age residing in the U.S. Mountain West were recruited. A 15-minute, online survey was utilized. The independent variable was number of volunteer hours per week (mean = 6.25, $SD = 4.85$). The dependent variable was social connectedness measured by five items positively worded from the five-point, Likert-type UCLA loneliness scale ($\alpha = .85$; mean = 4.26, $SD = 0.59$). Drawing from the self-stereotypes of aging scale, the indirect effects of five internalized positive (e.g., “wise” and “capable”) and five negative (e.g., “grumpy” and “helpless”) age stereotypes were tested. Results indicate that increased internalized positive, not negative, age stereotypes partially mediated the relationship between volunteer hours and increased social connectedness, while holding constant age, gender, race, functional limitation, education, employment, length of volunteering, and previous volunteer experience. Although positive age stereotypes have long been considered a form of ageism, the results of this study suggest that internalizing positive age stereotypes may function as a form of esteem to promote enhanced psychosocial health as people age.

THE MEDIATING EFFECT OF SOCIAL SUPPORT OF OLDER KOREAN ADULTS' VOLUNTEERING ON THE RELATIONAL AND LIFE SATISFACTION

Meeryoung Kim, *Daegu University, Daegu, Kyongsangbukto, Republic of Korea*

For older adults wanting to maintain good health and stay active after retirement, volunteering is an important activity. Social capital is important factor for volunteering. Social support as a social capital, is a contributing factor that is important and needed by older adults who volunteer. Also as a result from volunteering, older adults can increase their social support through volunteering. This study examined whether emotional and instrumental social support mediate volunteering on both relational and life satisfaction. This study used the 6th additional wave of the Korean Retirement and Income Study (2016). Subjects for this study are over 60 years old and the sample size is 280. For data analysis Baron and Kenny's triangular regression analysis and the Sobel test were used for data analysis. Demographic variables were controlled. Volunteer variables such as volunteering asked by others or self-motivated, whether only one type of volunteering or more, professional volunteering, and volunteer hours were used as independent variables. Emotional and instrumental social support were used as mediators. Relationship satisfaction and life satisfaction variables were used as dependent variables. Emotional and instrumental support partially mediate volunteering asked by others to influence relational and life satisfaction. In addition, emotional support and instrumental support mediate “more than one kind of volunteering” to influence relationship satisfaction. As such, emotional and instrumental support through volunteering has a mediating effect on relationship satisfaction and life satisfaction.

THE RELATIONSHIP BETWEEN OCCUPATION TYPES, EDUCATION, AND VOLUNTEER BEHAVIORS AMONG OLDER AMERICANS

Patrick Ho Lam Lai,¹ Cal Halvorsen,² and Christina Matz,²
1. *Boston College School of Social Work, Chestnut Hill,*

Massachusetts, United States, 2. Boston College, Chestnut Hill, Massachusetts, United States

Research shows that productive engagement in later life, such as paid work and volunteering, is associated with health and wellbeing. From a life-course approach, personal history and experiences developed from occupations earlier in life may affect individual's willingness and ability to volunteer in later life; reciprocally, volunteering tends to extend networks and roles from their previous work after retirement. Further, education, which influences career development, indirectly affects late-life volunteering. Using data from 329,938 individuals aged 50 to 85 in more than 700 occupations from the Volunteer Supplement of Current Population Survey since 2010, this study found that older adults had higher volunteer rates (40%) when their current or latest jobs require more human interactions, compared to those jobs were mainly characterized as office work (31%) and jobs not requiring much human interaction (21%). More specifically, occupations with higher volunteering rates were more likely to be related to social, educational, or spiritual sectors. Some careers seem to provide skills and networks needed in volunteer roles, such as accounting clerks (ranked 12th in volunteering) and museum technicians (ranked 13th). Diverse educational levels make the relationship between occupation and volunteering more complex. For instance, those older adults without a high school diploma and who have office work as their current or latest job (16%) have higher volunteering rates than those occupations requiring (14%) or not requiring much human interaction (10%). Policymakers can take the human interactions and skills needed in careers and educational levels into account when thinking of strategies to promote volunteering.

THE RELATIONSHIP OF CAREERS WITH PEOPLE INTERACTIONS AND VOLUNTEERING BETWEEN GENDER-RACIAL GROUPS IN LATE-LIFE

Patrick Ho Lam Lai, *Boston College School of Social Work, Chestnut Hill, Massachusetts, United States*

Prior research showed that ethnic minorities in late-life tended to participate less in volunteering, compared to Whites. Older women, in general, spent more time volunteering than older men in the United States. Previous studies showed that occupational statuses, but have not yet discussed occupation categories, affected older adults' volunteering. The Current Population Survey dataset was utilized in this study to explore the relationship between careers with or without people interactions and volunteering of Americans aged 50 to 85 in an intersectionality lens. Regarding races, older African Americans who worked in occupations requiring human interactions, had almost double volunteering rate than those occupations not requiring these interactions. In respect of genders, compared to older men who worked in jobs requiring human interactions, the volunteer rate of those not requiring human interactions was 81% less. Either older African Americans or older men had more associations between their human interactions in career and their volunteering rate, than other racial groups or gender groups individually. Considering races and genders together, comparing to older Asian men who worked in fields needed interactions with others, the volunteering rate of those who did not work in these fields was 52% less. The association of

older Asian men between fields requiring human interactions and volunteering rate was the least, among various gender-racial subgroups. Older adults with different racial-gender identities may face varying experiences in different types of occupations. Social and cultural factors among these identities are discussed to better understand the relationships between careers and volunteering in late-life.

VOLUNTEERING AND CHRONIC INFLAMMATION IN LATER LIFE: IS SUSTAINED VOLUNTEERING BENEFICIAL FOR HEALTH?

Mallory Bell,¹ Madison Sauerteig,² and Kenneth Ferraro,²
1. *Purdue, West Lafayette, Indiana, United States*, 2. *Purdue University, West Lafayette, Indiana, United States*

Although research on the health benefits of volunteering has proliferated in recent decades, most studies have focused on whether or not a person volunteers or the monthly frequency of volunteering. This study examines whether sustained volunteering has health benefits above and beyond occasional or short-lived volunteering. To investigate the salubrious effects of volunteering, the present study considers sustained volunteering engagement in terms of both formal and informal volunteering. Using four waves of data from the Health and Retirement Study, we assess the influence of sustained volunteering on chronic inflammation, measured by C-reactive protein (CRP). Results reveal that sustained engagement in formal and informal volunteering is related to lower CRP concentration, but this association is partly mediated by adult health and socioeconomic factors. Although sustained volunteering is associated with lower levels of chronic inflammation, older adults who maintain their volunteering over time are a select category of adults, characterized by higher education and wealth and better health.

WHO VOLUNTEERS? RESULTS FROM A REGULAR COGNITIVE MONITORING STUDY

Britney Veal, Nasreen Sadeq, Taylor Atkinson, and Ross Anel, *University of South Florida, Tampa, Florida, United States*

Previous research indicates volunteering promotes well-being of individuals and communities. Volunteering in later-life may buffer some of the negative health effects experienced during retirement, facilitating opportunities for older adults to engage in meaningful activities and stay active. The current study examined characteristics of older adults who volunteered outside of participation in a regular cognitive monitoring study. All 124 members (M= 76.87, SD= 7.47; 80 volunteers, 44 non-volunteers) of a regular cognitive monitoring study, requiring completion of a 15-minute cognitive online test once a month, with complete data on personal characteristics, volunteer activities, as well as study adherence and dropout rates were included. ANCOVA and logistic regression analyses adjusted for sociodemographic characteristics were used to assess differences between volunteers and non-volunteers. Results indicated that volunteers were less educated ($p < .05$), and slightly more likely to be younger and women compared to non-volunteers. There were no differences in cognitive performance ($ps > .05$). Volunteers had lower scores for neuroticism ($p = .02$) and were marginally higher agreeable and extraverted ($ps < .09$). Volunteers needed more reminders to complete the monthly test ($ps < .01$) but had lower dropout

rates ($p = .001$). The most frequent type of volunteer activity reported was religious. Volunteers were motivated mainly by altruism, although most reported multiple reasons such as building social relationships and feeling important. Findings provide information about characteristics that can help identify older adults who are likely to volunteer. Results regarding study adherence may have implications for promoting recruitment and retention among older adult volunteers.

Session 9130 (Poster)

Cognition and Cognitive Impairment

AN INNOVATIVE TRANSITIONS MODEL OF CARE FOR DELIRIUM: "DDEFY DELIRIUM" A PILOT FEASIBILITY RANDOMIZED TRIAL

Ariba Khan,¹ Marianne Klumph,² Alexander Schwank,² Sandy Hubatch,² Jonny Macias Tejada,² Colleen Galambos,³ Michelle Simpson,² and Michael Malone,² 1. *Advocate Aurora Health Care, Milwaukee, Wisconsin, United States*, 2. *Advocate Aurora Health, Milwaukee, Wisconsin, United States*, 3. *University of Wisconsin- Milwaukee, Milwaukee, Wisconsin, United States*

In current standard practice, without a structured process for delirium follow up, older individuals and their family caregivers seemed to be lost, as they transitioned from hospital to home. The aim of this study was to pilot test a theoretical post-hospital model of care (DDEFY delirium) to mitigate the complications in patients who had hospital delirium. This is a pilot feasibility randomized controlled trial for patients with hospital delirium. The intervention was carried out by a delirium transitions nurse with personalized interdisciplinary team recommendations. DDEFY delirium intervention encompasses: Diagnose cognitive disorder; review Drugs; Educate patient/family; assess Function; Your health goals. During COVID-19 pandemic a virtual intervention group was created. Thus, three groups were analyzed: control, intervention, and virtual intervention. Among the 35 participants (mean age 80 years (SD10), 40% Black, 46% female), 40% had a diagnosis of dementia, mean Charles Deyo score was 6.4, mean number of medications 11.4 (3.2), and a mean anticholinergic medication burden was 2.4. The intervention group and virtual intervention group rates were: recruitment: 44.6 %vs8.8%, feasibility: 97%vs97%, fidelity:100%vs100%, 30-day readmission 28.6%vs0%, and 30-day ED visits: 0 vs.1. There were no differences in 30-day readmission rates between control vs intervention ($p = 1.0$), control vs virtual intervention ($p = .53$), nor comparing all 3 groups ($p = .49$). The results of this pilot study determined that delivering DDEFY intervention to patients with delirium is feasible. Lessons learned from conducting this study will help us design a larger trial with modifications for older patients with delirium who transition from hospital to home.

BEST PRACTICES TO OVERCOME BARRIERS TO CAPACITY EVALUATIONS

Ronan Factoria, and Saket Saxena, *Cleveland Clinic, Cleveland, Ohio, United States*

Because of the increasing incidence of elder abuse and financial exploitation, Adult Protective Services (APS) cases

open for these individuals often rely on capacity evaluations conducted by a clinician to facilitate legal assignment of a surrogate decision maker. Despite this growing need, the number of physicians willing and capable of performing them is limited. Barriers reported by physicians reportedly impair their ability to conduct these evaluations include absence of relevant case information and lack of knowledge about the process itself. Geriatricians and related clinicians often perform these assessments. Sharing best practices with internists and family physicians may help overcome these barriers. A survey of geriatric medicine providers was conducted to identify essential components and questions necessary in the assessment of general decision making capacity. Twenty-nine providers at 6 academic institutions in Ohio responded to the survey and its follow-up inquiries. Though variability existed in evaluation styles and content between providers, a uniform set of recommendations was able to be generated. A total of 13 different summary recommendations were generated from this survey. Necessary components to these evaluations include (1) performance of cognitive testing (2) obtaining collateral information regarding functional status from another trusted individual (3) assessing the individual's insight into any reported functional impairments or safety concerns by explaining discrepancies between that individual's own observations and reported concerns from the trusted individual, and (4) using hypothetical situations to assess a person's judgment and reasoning in addressing any gaps in care or safety concerns raised during the interview.

DAILY ALCOHOL USE COVARIES WITH DAILY CONCENTRATION PROBLEMS ACROSS THE LIFESPAN: FINDINGS FROM THE MIDUS REFRESHER

Jacqueline Mogle,¹ Ashley Linden-Carmichael,² Sara Miller,³ and David Almeida,³ 1. *Penn State University, University Park, Pennsylvania, United States*, 2. *Penn State University, State College, Pennsylvania, United States*, 3. *Pennsylvania State University, University Park, Pennsylvania, United States*

Alcohol use is typically associated with impaired cognitive functioning on tasks related to attention and concentration. However, it remains unclear whether these impairments persist across days in ways that are noticeable to the individual. We examined this using the daily diary project of the Midlife in the United States Refresher cohort. Participants ($n=710$; $Mage=50.5$; range 25-75) completed 8 nights of telephone-based diaries ($Mdiaries=6.87$) that included questions about daily alcohol use ("how many drinks did you have today?") and five items assessing concentration (e.g., "today, did you have difficulty concentrating?") rated on a scale (1=none of the time to 5=all of the time). Using autoregressive multilevel models, we examined how same and previous day alcohol use related to perceived difficulties with concentration. Greater total alcohol use over the diary period was related to reports of concentration problems ($b=.31$, $SE=.10$, $p=.002$) though current day ($b=-.03$, $SE=.04$, $p=.49$) and previous day alcohol use ($b=.05$, $SE=.04$, $p=.23$) were not. The association between previous day use and concentration problems was qualified by an interaction with total alcohol use ($b=-.07$, $SE=.03$, $p=.002$). Individuals who drank less alcohol in general, experienced greater perceived concentration problems following the days on which they did drink ($b=.14$,

$SE=.07$, $p=.03$) relative to those who drank more alcohol across the diary period ($b=-.04$, $SE=.04$, $p=.36$). This relationship did not vary based on age, sex, or education. These results suggest that daily alcohol use could impair concentration across days, particularly for those adults who tend to consume less alcohol.

DAILY COGNITIVE DIFFICULTIES AND SOCIAL EXPERIENCES AMONG OLDER ADULTS

Ruixue Zhaoyang,¹ Jacqueline Mogle,² Karra Harrington,¹ and Martin Sliwinski,¹ 1. *The Pennsylvania State University, University Park, Pennsylvania, United States*, 2. *Penn State University, University Park, Pennsylvania, United States*

Self-reported cognitive difficulties are common in older adults and may be an early indicator of future cognitive decline or dementia. In past retrospective reports, cognitive difficulties have been linked with differences in social engagement or social relationships among older adults. However, little is known about how self-reported cognitive difficulties in daily life, such as memory lapses, relate to older adults' daily social experiences. This study examined how self-reported cognitive difficulties were related to older adults' daily social interactions and loneliness. Data were drawn from 312 community-dwelling older adults (aged 70 to 90 years) who reported their social interactions and loneliness throughout the day (five times) as well as cognitive difficulties (e.g., memory lapses, problems with attention) at the end of each day for 14 days. Multilevel models revealed that participants reported fewer memory lapses on days when they reported more frequent interactions with family members ($p=.041$). Higher levels of disruptions to daily activities caused by cognitive difficulties, in turn, predicted higher levels of loneliness the next day ($p=.006$), but not changes in social interactions the next day. At the between-person level, more memory lapses in daily life were associated with less frequent social interactions with friends, but more frequent unpleasant social interactions and higher levels of loneliness on average. These results suggest that older adults' self-reported cognitive difficulties were dynamically associated with their social interactions and loneliness at the daily level and played an important role in older adults' social life and well-being.

DEVELOPMENT AND EVALUATION OF TREATMENT ADHERENCE INTERVENTIONS FOR OLDER ADULTS WITH MCI USING IOT DEVICES

Jinhee Shin,¹ Eunhee Cho,¹ Gwang Suk Kim,¹ Heejung Kim,² Byoung Seok Ye,² and Chang-Gi Pack,³ 1. *Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 3. *University of Illinois at Chicago, Seoul, Illinois, United States*

For older adults with mild cognitive impairment (MCI), treatment adherence is essential to prevent and delay dementia. Older adults with MCI should maintain treatment for chronic diseases, exercise regularly, and adhere to treatment to maintain health status. There is a lack of comprehensive interventions to promote treatment adherence (medication adherence and physical activity) for older adults with MCI. The purpose of this study was to develop an internet of things (IoT)-based real-time treatment adherence

for old adults with MCI and examine the effectiveness of the program. This study was a randomized controlled trial. The patients were enrolled from the neurology outpatient department clinic at a hospital in Korea. The subjects were 18 in the experimental group and 20 in the control group. This study intervention was IoT-based medication adherence device and real-time monitoring sever plus wrist wearable device. The study consists of a 10-week intervention period. The intervention program was provided for only the experimental group and the control group with a wearable device and usual care. Assessments were conducted at baseline, 6 weeks, and 10-weeks. A mixed-effects model was used in the analysis to evaluate the program. The IoT-based treatment adherence intervention was effective in improving medication adherence over time ($\beta = 11.465$, $p < .001$), physical activity (K-PASE) ($\beta = 27.376$, $p < .001$) and average the number of steps per week ($\beta = 3202.53$, $p < .001$). Health care providers can use this program to improve treatment adherence for chronic disease management and dementia prevention of older adults with cognitive impairment.

DEVELOPMENT OF A LOCATOR DEVICE USABILITY SCALE FOR PERSONS WITH DEMENTIA AT RISK OF GETTING LOST

Noelannah Neubauer,¹ Christa Spenrath,² Serrina Philip,¹ Christine Daum,³ Lili Liu,¹ and Antonio Miguel-Cruz,²
 1. *University of Waterloo, Waterloo, Ontario, Canada*, 2. *University of Alberta, Edmonton, Alberta, Canada*,
 3. *University of Waterloo, Edmonton, Alberta, Canada*

There is an increasing number of persons living with dementia who live alone. Recent COVID-19 pandemic restrictions have resulted in more persons receiving care remote through information and communication technologies. Locating technologies can be a tool to help care partners monitor their loved ones living with dementia. These devices can also mitigate risks associated with going missing, by reducing time for search and returning the lost person home safely. However, there is no clear, standardized approach to assess the usability of these devices. The purpose of this study was to develop a locator device usability scale for persons living with dementia at risk of getting lost. A two-phase study that utilized a multi-method design and included participatory and iterative strategies was conducted. In the first phase, an item pool was generated through online focus groups with service providers, technology developers, care partners and persons living with dementia. The second phase refined the item pool using an online survey and online focus groups with the same stakeholder groups. Five overarching categories were identified as important for the usability of locating device: features, inclusivity, simplicity, aesthetic appeal, and ethics. Participants identified the need for multiple versions of the usability scale including one specifically for persons living with dementia. The newly developed locator device usability scale can enhance the acceptance of these devices, thereby supporting remote caregiving and promote the safety and autonomy of persons living with dementia.

FACTORS THAT INFLUENCE THE EMOTIONAL IMPACT OF MEMORY PROBLEMS IN OLDER ADULTS: A MIXED-METHODS STUDY

Emily Bratlee-Whitaker,¹ Nikki Hill,¹ Jacqueline Mogle,¹ Rachel Wion,² Caroline Madrigal,³ and Sakshi Bhargava,¹

1. *Penn State University, University Park, Pennsylvania, United States*, 2. *Indiana University, Indiana University, Indiana, United States*, 3. *Providence VA Medical Center, Providence VA Medical Center, Rhode Island, United States*

Older adults' experiences with memory problems may be an important indicator of current and future well-being; however, these experiences and their impacts are poorly characterized, particularly in those with co-occurring affective symptoms. The purpose of this mixed-methods study was to examine how the experience of memory problems influences emotional well-being in older adults without dementia, and whether this differs based on cognitive status and current depressive symptoms or anxiety symptoms. A convergent parallel mixed methods design was used in which quantitative and qualitative data were collected simultaneously, analyzed separately, and then integrated to determine how participants' experiences differed. Community-dwelling older adults ($n=49$, Mage = 74.5, 63% female) without severe cognitive impairment completed study questionnaires and two individual, semi-structured interviews. Five themes were identified that described the influence of memory problems on emotional well-being: Evoking Emotions, Fearing Future, Undermining Self, Normalizing Problems, and Adjusting Thinking. The extent to which memory problems impacted emotional well-being depended on multiple factors including current affective symptoms (primarily anxiety), characteristics of the experience (such as judgments of its importance), as well as personal experience with dementia. Notably, there were no thematic differences in the emotional impact of memory problems between older adults with normal cognition and those with evidence of mild cognitive impairment. Our findings suggest that thorough assessment of reports of memory problems, regardless of cognitive testing outcomes, should consider co-occurring subsyndromal affective disorders as well as older adults' evaluations of how memory problems influence their daily lives and well-being.

FALL PREVENTION IN ADULTS WITH COGNITIVE IMPAIRMENT: SYSTEMATIC REVIEW AND META-ANALYSIS

Megan Racey,¹ Maureen Markle-Reid,¹ Muhammad Usman Ali,¹ H el ene Gagn e,² Susan Hunter,³ Jenny Ploeg,¹ Richard Sztramko,¹ and Diana Sherifali,¹
 1. *McMaster University, Hamilton, Ontario, Canada*, 2. *Ontario Neurotrauma Foundation, Toronto, Ontario, Canada*, 3. *Western University, London, Ontario, Canada*

Cognitive impairment increases an individual's risk of falls due to the role cognition plays in gait control. Older adults with dementia fall 2-3 times more than cognitively healthy older adults and there is a lack of evidence for effective fall prevention interventions for community-dwelling cognitively impaired adults. We conducted a systematic review and meta-analysis to investigate the effectiveness of fall prevention interventions in improving falls, perceived risk of falls, gait, balance, and functional mobility. We searched 7 databases for interventions involving community-dwelling adults ≥ 50 years with mild to moderate cognitive impairment. Reviewers screened citations, extracted data, assessed risk of bias and certainty of evidence (GRADE). We performed a meta-analysis of 509 community-dwelling adults (mean age 67.5 to 84.0 years) with mild to moderate

cognitive impairment from 12 randomized controlled trials (8 exercise interventions, 3 multifactorial, and 1 providing medication). Interventions had medium significant effects on perceived risk of falls (SMD -0.73 [-1.10, -0.36]), balance (SMD 0.66 [0.19, 1.12]), and timed up and go test (SMD -0.56 [-0.94, -0.17]) and small significant effects on gait speed and control (SMD 0.26 [0.08, 0.43]) with moderate certainty of evidence. There were no significant effects for falls. Sub-analysis showed that exercise and studies at low risk of bias remained significant for balance and perceived risk of falls. The effect of fall prevention interventions on falls remains unclear; exercise interventions are effective at addressing fall risk factors. However, high quality and longer studies with adequate sample sizes are needed to determine their effectiveness on falls.

HIGHER SERUM BDNF LEVELS ARE ASSOCIATED WITH LOWER RISK OF COGNITIVE DECLINE IN OLDER ADULTS :THE OTASSHA STUDY

Yoshinori Fujiwara,¹ Kazushige Ihara,² Mitsugu Hachisu,³ Hiroyuki Suzuki,¹ Hisashi Kawai,¹ Masahiro Hashizume,⁴ Hirohiko Hirano,¹ and Shuichi Obuchi,¹ 1. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan*, 2. *Hirosaki University, Aomori, Alabama, Japan*, 3. *Showa University, Tokyo, Alabama, United States*, 4. *Toho University, Tokyo, Tokyo, Japan*

Introduction: There has been growing interest in the use of circulating levels of brain-derived neurotrophic factor (BDNF) in the blood as a biomarker in the context of patients with Alzheimer's and other neurodegenerative diseases. Prospective data on cognitive decline in the broad older population, however, remain limited. We assessed the relationship of serum BDNF levels with short-term decline in cognitive functioning of community-dwelling older adults. **Methods.** Prospective study of 405 adults 65-84 years old without dementia in Tokyo, Japan. The Montreal Cognitive Assessment-Japanese version (MoCA-J) and its subscales were used. Linear regression assessed standardized differences in test score differences between baseline (2011) and follow-up (2013) visits, according to baseline serum BDNF quartiles, with adjustment for baseline demographics, disease indicators, and cognitive scores. **Results:** Among participants who performed on the MoCA-J at baseline (scores in bottom quartile), cognitive decline was .65 (95% CI: .08 - 1.2; $p=.025$) standard deviations (SD) more pronounced in those with lowest than highest BDNF levels. Decline in executive function, but not in other subdomains, was also most pronounced in those with lowest baseline serum BDNF levels (difference: .32 SD; 95% CI: .08-.55; $p=.007$) **Conclusion:** Lower serum BDNF levels were associated with greater 2-year cognitive decline in community-dwelling older Japanese adults. Decline varied among cognitive subdomains, and baseline cognition. Research seeking to evaluate the added-value of serum BDNF for screening and/or health promotion initiatives involving physical activity, which has been linked to increment in BDNF levels, is warranted.

HOW OLDER ADULTS REDEFINE ITEMS ON THE PROMIS-57 PROFILE PATIENT-REPORTED OUTCOME MEASURE

Ann Gruber-Baldini,¹ G. Jay Unick,² Veronica Fallon,³ Philip Heiser,³ Kimberly Bambarger,³ and Lisa Shulman,³

1. *University of Maryland School of Medicine, Baltimore, Maryland, United States*, 2. *University of Maryland, Baltimore, Baltimore, Maryland, United States*, 3. *University of Maryland School of Medicine, Baltimore, Maryland, United States*

PROMIS® measures provide valid assessment of patient-reported outcomes, but have not been validated in older adults (especially aged 80+), including those with cognitive impairment. The objective of this project was to study how age-related role change effected the understanding of items on the PROMIS-57 Profile using cognitive interviews. Cognitive interviews were conducted with 38 adults, age 65+ with MoCA scores 10-30. Preliminary codes were created and then codes were added or modified as needed. Each interview was coded independently by two coders with differences resolved by consensus. The sample was 47% age 80+, 45% female, 18% African American, and 32% had a MoCA score between 10-17 (cognitively impaired). Thematic analysis of codes indicated that participants endorsed little or no impairment when they adapt to physical or cognitive disabilities by using economic means, instrumental support, physical aids, or by reducing activities. One respondent using grocery delivery services described no difficulty running errands or shopping. Another respondent reported no difficulty walking 15 minutes because they use a cane. Some reported no difficulty engaging in social roles when they restricted their activities due to disability or lack of appropriate social activities. Age-related changes effected responses on PROMIS-57 items. Findings suggest that age-related changes bias individuals to indicate less physical and cognitive impairment than their actual level of function. Physical functioning items show more bias for individuals with financial or instrument support, and social role items show more bias for those with restricted social networks.

INFLAMMATION AND COGNITIVE FUNCTIONING IN OLDER ADULTS: THE ROLE OF GENDER AND OBESITY

Melody Moloci Noss,¹ Summer Millwood,² and Kate Kuhlman,¹ 1. *University of California, Irvine, Irvine, California, United States*, 2. *University of Denver, Denver, Colorado, United States*

Systemic inflammation is associated with steeper cognitive decline over time. Identifying potential moderators of inflammation is crucial for understanding inflammation's contribution to abnormal cognitive decline. This study examined whether inflammation predicted changes in cognitive functioning over time and explored the moderating effects of sex and BMI on this association. Data was collected from a longitudinal nationally representative data set. (Health & Retirement Study). C-reactive protein (CRP) and global cognitive functioning assessments were collected from the 2006/2008 and 2010/2012 waves. Participants, $n=7,483$, Age =71.39 years (SD = 9.24) , 60.2% female, were categorized into groups based on BMI (i.e. normal, overweight, and obese). Sex and BMI significantly moderated the association between increased hs-CRP and lower cognitive functioning, $b = -.22$ (SE = .09), $p = .017$. Women with high BMI exhibit twice the risk of low cognitive functioning, $b = -.49$ (SE = .07), $p < .0001$, compared to men with high BMI, $b = -.21$ (SE = .08), $p = .01$. Men with normal

BMI exhibited twice the risk of low cognitive functioning, $b = -.49$ ($SE = .08$), $p < .0001$, compared to women with normal BMI, $b = -.24$ ($SE = .06$), $p = .0001$. Inflammation and BMI are modifiable factors that may prevent or slow down abnormal cognitive decline. Understanding the potentially sex-dependent role of adipose tissue in the impact of inflammation on cognitive function may be critical to understanding the pathogenesis of cognitive impairment late in life as well as identifying efficacious intervention targets.

INTERACTIONS BETWEEN PLASMA AMYLOID AND AGING MARKERS TO DETERMINE CLINICALLY MEANINGFUL COGNITIVE DECLINE

Wan-Hsuan Lu, Kelly Giudici, Bruno Vellas, and Philippe de Souto Barreto, *CHU Toulouse: Centre Hospitalier Universitaire de Toulouse, G erontop ole de Toulouse, Institut du Vieillessement, Midi-Pyrenees, France*

Background: Brain amyloidosis is a well-known pathological hallmark of Alzheimer's disease (AD) and can be early identified by measuring plasma amyloid- β ($A\beta$) status. Growing evidence implicates the biological mechanisms of aging, including chronic inflammation, mitochondrial dysfunction and neurodegeneration, in AD pathogenesis. This study aims to investigate the interactions between plasma $A\beta$ status and aging markers on clinically meaningful cognitive decline. **Methods:** This secondary analysis from Multidomain Alzheimer Preventive Trial (MAPT) enrolled 401 community-dwelling older adults (mean age \pm SD: 76.7 \pm 4.6 years) who had clinical dementia rating (CDR) scale as 0 or 0.5, and who had their plasma biomarkers measured: amyloidosis: $A\beta_{42/40}$ ratio; inflammatory: tumor necrosis factor receptor type 1 (TNFR-1), interleukin-6 (IL-6), monocyte chemoattractant protein-1 (MCP-1), C-reactive protein (CRP); mitochondrial dysfunction: growth differentiation factor 15 (GDF-15); neurodegeneration: neurofilament light chain (NfL). Cognitive decline was determined by diagnosed dementia and worsening CDR status. Cox regression and moderation modeling were applied to examine the interrelationships between biomarkers and risk of cognitive decline. **Results:** Among 401 participants, 43.9% were cognitive normal (CDR=0) and 56.1% were mild cognitive impairment (CDR=0.5) initially. After 3.3 \pm 1.1 years of follow-up, 7.0% of population evolved dementia and 34.2% had worsening CDR status. GDF-15 and NfL presented prospective associations with incident dementia. However, risk of dementia associated with plasma $A\beta$ did not change after considering the serum level of GDF-15 and NfL. **Conclusion:** The markers of mitochondrial dysfunction and neurodegeneration did not partially explain the associations between plasma $A\beta$ status and cognitive decline in older adults.

LONGITUDINAL ASSOCIATION OF EXECUTIVE FUNCTION AND BALANCE IN COMMUNITY-DWELLING OLDER ADULTS

Jennifer Blackwood,¹ Reza Amini,² Gerry Conti,² Quinn Hanses,³ Rebekah Taylor,⁴ Rachele Naimi,² and Deena Fayyad,⁵ 1. *University of Michigan--Flint, Michigan, United States*, 2. *University of Michigan-Flint, Flint, Michigan, United States*, 3. *University of Michigan - Flint, University of Michigan-Flint, Michigan, United States*, 4. *University of Michigan - Flint, Flint, Michigan, United States*, 5. *University of Michigan - Flint, Flint, Michigan, United States*

States, 5. *University of Michigan-Ann Arbor, Ann Arbor, Michigan, United States*

Declines in Executive Function (EF) are associated with balance in community-dwelling older adults with Mild Cognitive Impairment (MCI). While this has been examined in cross-sectional studies, no longitudinal studies describe change over time. The purpose of this study was to examine how performance on the components of the Short Physical Performance Battery (SPPB) are associated with EF in community-dwelling older adults who transition into MCI. This secondary data analysis employed eight years of data from the National Health and Aging Trends Study dataset (2011 – 2018) with 1,225 participants in all eight waves (balanced). EF was measured with the Clock Drawing Test and SPPB balance tests included side-by-side, semi-tandem, full tandem, and single leg stance with eyes open or closed. Longitudinal ordered logistic regression was used to examine associations between each balance measure and EF while controlling for comorbidity, function, depression, gender, age, and ethnicity. EF was significantly associated with tandem, semi-tandem, and single leg stance after controlling for covariates. One point increase in SPPB can reduce the risk of EF impairment by 8.2% (Odds Ratio (OR)=0.918, $p < 0.001$). Among SPPB components, semi-tandem (OR=0.468) and side-by-side (OR=0.472) were the strongest predictors of EF impairment. Declines in both EF and balance performance occurred over an eight-year period in adults. This may reflect common neural processes shared between the cognitive and motor areas of the central nervous system. Best practice suggests screening both balance (tandem, semi-tandem, or single leg stance) and EF in the clinical assessment of community-dwelling older adults.

LONG-TERM VISIT-TO-VISIT BLOOD PRESSURE VARIABILITY AND COGNITION: A SYSTEMATIC REVIEW OF OBSERVATIONAL STUDIES

Tomiko Yoneda,¹ Jamie Knight,¹ Amelia Zhang,² Graciela Muniz-Terrera,³ and Andrea Piccinin,¹ 1. *University of Victoria, Victoria, British Columbia, Canada*, 2. *University of Toronto, Toronto, Ontario, Canada*, 3. *University of Edinburgh, Edinburgh, Scotland, United Kingdom*

Existing literature suggests that in comparison to a single blood pressure (BP) measurement, or the mean of multiple recordings, BP variability (BPV) may reflect dysfunction in cardiovascular regulatory mechanisms, leading to compromised cognitive health. No systematic review has yet synthesized observational reports examining the association between cognition and long-term visit-to-visit BPV. In response, a comprehensive literature search was executed in December, 2019, and updated in December, 2020. Methodological approach was pre-registered (<https://osf.io/vmnuq/>). Of 1385 reports, 27 met eligibility criteria. Most executed secondary analyses using existing longitudinal datasets of older adults ($N=21$). Intervals between measurement occasions ranged from 30 days to four years, and follow-up ranged from 0.5-2.5 years. Most studies computed more than one index of BPV (range=1-6), and all included at least three BP recordings (range=3-12). Given extensive between-study variability in analytic approach (e.g., BPV and cognition treated as continuous and/or categorical variables; number of covariates

ranged 0-18), our team determined that meta-analyzing the results would be inappropriate. Despite heterogeneity in study characteristics, the majority (85.2%) reported that systolic BPV (sBPV) was negatively associated with cognition; specifically, higher sBPV was associated with cognitive impairment (N=9), cognitive decline (N=6), and/or risk of dementia (N=5). Four studies also revealed higher sBPV in individuals with dementia compared to controls. Three studies reported no association, while one reported a positive significant association between BPV and cognition. Results were similar for diastolic BPV. Despite considerable heterogeneity in study characteristics, greater variability in visit-to-visit BP appears to be consistently associated with adverse cognitive outcomes.

MANIFESTATIONS OF AGING IN VIRTUAL REALITY IMPLEMENTATION OF ROD AND FRAME TEST

Michal Adamski,¹ Mirosław Latka,² Anna Latka,³ and Bruce West,⁴ 1. *Wrocław University of Science and Technology, Wrocław, Dolnoslaskie, Poland,*

2. *Wrocław University of Science and Technology, Wrocław, Dolnoslaskie, Poland,* 3. *Opole Neuropsychiatric Hospital, Opole, Opolskie, Poland,* 4. *Army Research Office, Research Triangle Park, North Carolina, United States*

Senior adults' reliance on the visual frame of reference for spatial orientation is a manifestation of an age-related shift in cognitive style from field independence to field dependence. We implemented a virtual reality rod and frame test (VR-RFT) to assess visual field dependence (VFD) in n=39 young adults (20-30 years old) and n=43 seniors (60 years old and above). The subjects were asked to determine subjective visual vertical (SVV) for 19 angles of frame tilt (ranging from -45 degrees to 45 degrees in steps of 5 degrees). The strong VFD of seniors was manifested not only by the increased error in the determination of SVV (SVVE) but also in its distribution. For small and large frame tilt angles, seniors' SVVE skewness and kurtosis were greater than those of young adults. The SVVE median dependence on frame tilt may be accounted for with a phenomenological model whose two parameters describe the strengths of primary (P) and secondary (S) visual attractors which subjects use to infer SVV: the edges of the frame and its imaginary diagonals. For young adults, these parameters were: PY=14.91 and SY=12.51. For seniors, we observed an over 50% increase in the strength of the primary attractor PS=26.31 while the strength of the secondary one was only weakly affected by aging: SS=13.74. We demonstrate that the asymmetry between the strength of attractors significantly contributes to SVVE made by seniors at large frame tilts. We hypothesize that a variant VR-RFT may be used in rehabilitation to reduce excessive VFD.

PREDICTING QUALITY OF LIFE WITH PHYSICAL AND COGNITIVE FUNCTIONING AMONG OLDER ADULTS WITH COGNITIVE IMPAIRMENT

Rhayun Song, Moonkyoung Park, Jisu Seo, Fan Xing, Yuelin Li, and Ahyun Ryu, *Chungnam National University, Dae Jeon, Taejon-jikhalsi, Republic of Korea*

Purpose: Older adults experience abnormal declines in physical and cognitive functioning that increase their risk of dependence, subsequently quality of life. This study aims to explore the relationship between physical and cognitive

functioning, and to predict quality of life among older adults with mild cognitive impairment. Methods: Survey was conducted with older adults registered at dementia support centers. Seventy-four older adults signed the consent form and participated in the study. physical functioning consisted of grip strength, balance (OLS), Timed up and go, and activities of daily living. Cognitive functioning was measured by K-MOCA. SF-12 was used to assess quality of life. Results: The participants was 76 years old on average, more women (75.4%), and mostly elementary or less education level (60.9%). Physical functioning explained 22.1% of variance in cognitive functioning after controlling for age and gender (F change=4.789, p=.002). Balance (OLS: t=2.304, p=.024) and grip strength (t=2.207, p=.031) was significant predictors. Physical and cognitive functioning explained 36.7% of variance in quality of life after controlling for age and gender (F =5.466, p<.001). Indicators of physical functioning, TUG (t=-3.252) and grip strength (t=-2.633), were the most significant predictors of quality of life, while cognitive function explained additional 3.1% of variance in quality of life (F=3.216, p=.078). Conclusion: Physical functioning were significant predictors of cognitive functioning, subsequently to quality of life among older adults with cognitive impairment. Health promoting strategies should focus on improving physical functioning of this population to maintain or prevent cognitive declining, and to promote quality of life.

RELATIONSHIP BETWEEN TYPE 2 DIABETES CONTROL AND COGNITION IN OLDER ADULTS: FINDINGS FROM NHANES

Rozmin Jiwani,¹ Sara Espinoza,¹ Jing Wang,² and Monica Serra,³ 1. *University of Texas Health Science Center San Antonio, San Antonio, Texas, United States,* 2. *University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States,* 3. *UT Health San Antonio - Barshop Institute, San Antonio, Texas, United States*

Cognitive health has emerged as an important public health concern for America's aging population. Type 2 Diabetes (T2D) may be associated with an exacerbated decline in cognitive performance. This study aimed to examine the relationship between T2D control and cognitive performance in older adults (≥60 years) using the 2013-2014 National Health and Nutrition Examination Surveys. Participants who completed the following cognitive assessments were included: 1) Consortium to Establish a Registry for Alzheimer's Disease Word List (CERAD-WL), 2) Animal Fluency (AF), 3) Digit Symbol Substitution Test (DSST) (higher scores associated with better cognition). Participants were stratified by four groups: no T2D (N=557), treated/controlled T2D (controlled; N=41), treated/uncontrolled T2D (uncontrolled; N=120), untreated T2D (N=86), based on self-reported T2D treatment, fasting plasma glucose, and hemoglobin A1c. Logistic regression was used to examine the relationship between T2D control and cognition. We observed that those with uncontrolled and untreated T2D each had ~15% lower DSST than those with no T2D (P<0.01). CERAD-WL and AF were similar across all groups. Unadjusted analyses showed that individuals with 1) lower CERAD-WL were more likely to have controlled and untreated T2D, 2) lower AF were more likely to have controlled

and uncontrolled T2D, and 3) lower DSST were more likely to have uncontrolled and untreated T2D (P 's<0.05). After adjusting for significant demographics and cardiovascular risk factors, only having uncontrolled T2D was associated with lower DSST (β =-3.164, P =0.04). These data indicate the need for longitudinal studies to further explore dynamic relationship and causal pathway between T2D control and cognitive impairment.

RISK FACTORS FOR DEMENTIA ONSET IN OLDER ADULTS WITH METASTATIC RENAL CELL CARCINOMA

Samuel Miller,¹ Lauren Wilson,² Melissa Greiner,³ Jessica Pritchard,⁴ Tian Zhang,⁵ Deborah Kaye,² Harvey Cohen,² and Michaela Dinan,⁶ 1. *Yale University, Hamden, Connecticut, United States*, 2. *Duke University School of Medicine, Durham, North Carolina, United States*, 3. *Duke University, Durham, North Carolina, United States*, 4. *Duke University, Duke University, North Carolina, United States*, 5. *Duke Cancer Institute, Duke Cancer Institute/Durham, North Carolina, United States*, 6. *Yale University, New Haven, Connecticut, United States*

Renal dysfunction is a driver of dementia. It is also associated with renal cell carcinoma, possibly the result of the tumor itself or from cancer treatment. This study evaluates metastatic renal cell carcinoma (mRCC) as a risk factor for developing mild cognitive impairment or dementia (MCI/D) as well as the impact of RCC-directed therapies on the development of MCI/D. We identified all patients diagnosed with mRCC in SEER-Medicare from 2007-2015. The main outcome was incident MCI/D within one year of mRCC diagnosis or cohort entry. Exclusion criteria included age <65 at mRCC diagnosis and diagnosis of MCI/D within preceding year of mRCC diagnosis. Patients with mRCC ($n=2,533$) were matched to non-cancer controls ($n=7,027$) on age, sex, race, comorbidities and year. Cox proportional hazards regression showed that having mRCC (HR 8.52, 95% MCI/D 6.49-11.18, $p<0.001$) and being older (HR 1.05 for 1-year age increase, 95% MCI/D 1.03-1.07, $p<0.001$) were predictive of developing MCI/D. A second Cox proportional hazards regression of only patients with mRCC revealed that neither those initiating treatment with oral anticancer agents (OAs) nor those who underwent nephrectomy were more likely to develop MCI/D. Black patients had a higher risk of dementia compared to white patients (HR 1.92, 95% MCI/D 1.02-3.59, $p=0.047$). In conclusion, patients with mRCC were more likely to develop MCI/D than those without mRCC. The medical and surgical therapies evaluated were not associated with increased incidence of MCI/D. The increased incidence of MCI/D in older adults with mRCC may be the result of the pathology itself.

SOCIAL DISENGAGEMENT AND COGNITIVE FUNCTION: DOES THE ASSOCIATION VARY BY GENDER?

Bada Kang,¹ Eunhee Cho,² and Sarah Oh,² 1. *Mo-Im Kim Nursing Research Institute, Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Although social disengagement is considered to be a predictor of cognitive decline, and increase risk of Alzheimer's

and related dementias, little is known regarding the gender-specific association between social disengagement and cognition among Korean middle-aged and older adults. Korea's Confucianism-based gender roles provide unique contexts to examine gender differences in the influence of social disengagement on cognition. This study investigated the association between social disengagement and cognitive function in a nationally representative sample of Koreans aged 45 years or older ($N = 5,196$ women and 2,707 men), using data from the Korean Longitudinal Study of Aging (2008-2018). Results from the generalized estimating equation model showed that compared to consistent social engagement, consistent non-engagement was significantly associated with lower cognitive function among both genders. Transitioning from social engagement to non-engagement was significant for males only. Of various types of social activities (religious, senior center, sport, reunion, voluntary, political), consistent non-engagement in a senior center was most associated with lower cognitive function among both genders, while consistent non-engagement in religious activities was significant for females only. While household arrangements were not associated with cognition in men, widowed women had increased risk of cognitive decline than married women, as did women living in households of three or more people. Depression was a predictor of cognitive decline among males only. In this gender-specific study, we found that consistent participation in social activities, especially via membership in a senior community center, is beneficial in preventing cognitive decline among both genders.

SUBCLINICAL CARDIAC DYSFUNCTION AND COGNITIVE FUNCTION: A SYSTEMATIC REVIEW

Mario Maalouf,¹ Raymond Farah,² Sola Bahous,³ Kamal Matli,³ Adina Zeki Al Hazzouri,⁴ and Christy Costanian,³ 1. *Lebanese American University, Lebanese American University, Beyrouth, Lebanon*, 2. *Lebanese University, Beirut, Beyrouth, Lebanon*, 3. *Lebanese American University, Beirut, Beyrouth, Lebanon*, 4. *Columbia University, New York, New York, United States*

Background: Cardiovascular disease, and more recently, subclinical cardiac dysfunction have both been implicated as important risk factors for cognitive decline. Several measures have been used to detect subclinical cardiac dysfunction, with global longitudinal strain (GLS) emerging as an important and more sensitive indicator than traditional measures. Yet, the association of GLS with cognitive function remains relatively unexplored. Objective: The aim of this review is to systematically summarize the literature exploring the association between GLS and cognitive function. Methods: We conducted a systematic review of the literature following PRISMA guidelines using the following databases: PubMed, OVID Medline, Embase, Web of Science, and CINAHL. Inclusion criteria were observational studies published in English, measuring GLS and assessing cognitive function through neuropsychiatric tests or brain imaging. Quality assessment was done using the Newcastle Ottawa Scale. Results: The initial search revealed 394 studies, of which three met inclusion criteria and were included for final review. The three studies included were cross-sectional and of high quality. They all reported that lower GLS scores were associated? with worse cognitive function and more

brain abnormalities in both bivariate and multivariable analysis. Conclusion: Subclinical cardiac dysfunction, identified by GLS, was associated with worse cognitive function and presence of cerebral abnormality on brain imaging. The underlying mechanism could be attributed to dysfunctional autoregulatory and microvascular processes occurring in the brain vasculature. Further longitudinal studies are needed to better delineate the relationship between GLS and cognitive function.

THE ASSOCIATION BETWEEN LEISURE GAMES AND COGNITIVE FUNCTIONING AMONG OLDER ADULTS

Tyran Terada,¹ and Yeonjung Lee,² 1. *University of Hawai'i, Honolulu, Hawaii, United States*, 2. *University of Hawai'i at Mānoa, Honolulu, Hawaii, United States*

Stimulating leisure games have been shown to offer cognitive stimulation among older adults. This cross-sectional study examined the association between word games (crossword puzzles and scrabble) / cards and games (games such as chess) and cognitive functioning among adults aged 65 years and older (n=3271). All data were collected from the Health and Retirement Study (2016). Results from the hierarchical regression models suggest that higher levels of participation in word games (p<.01) and cards and games (p<.01) predicted higher levels of cognitive functioning. In the final model, after controlling for age, gender, ethnicity, marital status, education, and income, a total variance of 31 percent was explained. All covariates were statistically significant except marital status. Word games ($\beta=.117$, p<.01) and cards and games ($\beta=.054$, p<.01) had a significantly positive association with cognitive functioning. These findings suggest that participation in word games and cards and games are associated with cognitive functioning among older adults.

THE EFFECTS OF MILD COGNITIVE IMPAIRMENT ON FALL SEVERITY IN OLDER ADULTS

Megan Jones,¹ Sally Paulson,² Joshua Gills,¹ Anthony Campitelli,¹ Jordan Glenn,³ Erica Madero,³ Jennifer Myers,³ and Michelle Gray,¹ 1. *University of Arkansas at Fayetteville, Fayetteville, Arkansas, United States*, 2. *University of Arkansas at Fayetteville, Cincinnati, Ohio, United States*, 3. *Neurotrack Technologies, Redwood City, California, United States*

Falls affect more than 30% of older adults and are one of the leading causes of injury, hospitalization, and mortality in this population. Mild cognitive impairment (MCI) is one of the risk factors for falls in older adults. The purpose of this study is to determine if older adults with MCI have increased fall severity than older adults without MCI. Participants (n: 81: age: 79 ± 6) completed a Montreal Cognitive Assessment (MoCA) and a Hopkins Falls Grading Scale, a tool used to grade the severity of falls on a scale of 1-4 (1 = loss of balance without fall; 4 = fall requiring hospital admission). Participants were categorized as having MCI (score <26: N: 44: age: 81 ± 6.4) or non-MCI (score ≥26: n: 37: age: 77 ± 6). Groups were analyzed using a one-way ANOVA in SPSS to compare the severity of falls within the previous 12 months. There were no differences between groups for fall grade 1 (p =.22) or fall grade 2 (p =.45). There was a significant difference between groups for fall grade 3 (p =.04) and fall grade 4 (p =.05) with the MCI group having more of these falls

compared to the non-MCI group. Older adults with MCI had a higher number of falls requiring medical attention than older adults without MCI. Although falls are a risk in all older adults, those with MCI may be at higher risk of more injurious falls than older adults without MCI.

VITAMIN D, INSULIN-LIKE GROWTH FACTOR, AND COGNITIVE PERFORMANCE: AGE AND SEX VARIATIONS

Magdalena Tolea,¹ Stephanie Chrisphonte,² and James Galvin,² 1. *University of Miami Miller School of Medicine, Boca Raton, Florida, United States*, 2. *University of Miami Miller School of Medicine, Miami, Florida, United States*

Vitamin D has been consistently linked to better cognitive function in observational studies. This impact may be due in part through its influence on neurotrophins. Whether the relationships between vitamin D, neurotrophins, and cognition vary based on biological factors such as age and sex is unclear. Using data from a sample of 400 community-dwelling older (mean age=75.3±9.4; 47% female) participants in a cross-sectional study of cognitive aging, we assessed relationships between plasma 25-hydroxy-Vitamin D and performance on a neuropsychological battery modeled after the UDSv3.0. Moderation by age and sex and the impact of vitamin D on the relationship between Insulin-like Growth Factor-1 and cognitive performance were assessed by linear regression stratified by sex and age (median split at 76y). We found vitamin D to be positively linked to global cognition (MoCA: $\beta=0.095\pm0.025SE$, p<.001), working memory (Number Span Forward: $\beta=0.017\pm0.007SE$, p=0.011; Number Span Backward: $\beta=0.016\pm0.007SE$, p=0.028), episodic memory (Immediate Recall : $\beta=0.089\pm0.027SE$, p=0.001; Delayed Recall: $\beta=0.047\pm0.015SE$, p=0.002), attention and processing speed (Trail Making A: $\beta=-0.365\pm0.163SE$, p=0.026), executive function (Trail Making B: $\beta=-0.537\pm0.215SE$, p=0.014; Number-Symbol Coding: $\beta=0.139\pm0.057SE$, p=0.016), and an overall measure of cognitive function (z score: $\beta=0.049\pm0.018SE$, p=0.007). Most of these relationships were observed in women and younger older individuals (<76y). In addition, vitamin D increased the effect of IGF-1 on global cognition and memory by 13% and 8%, respectively. Our findings suggest that vitamin D-focused dementia prevention efforts would benefit if targeted to women and younger segments of the senior population and/or as an adjuvant to cognitive enhancement interventions.

Cognition I

Session 9135 (Poster)

AGE-RELATED DECLINE IN PRAGMATIC REASONING OF OLDER ADULTS

W.Quin Yow,¹ Jia Wen Lee,² and Xiaoqian Li,³ 1. *Singapore University of Technology & Design, Singapore, Singapore*, 2. *Singapore University of Technology & Design, Singapore University of Technology & Design, Singapore, Singapore*, 3. *Singapore University of Technology and Design, Singapore, Singapore*

As speech is often ambiguous, pragmatic reasoning—the process of integrating multiple sources of information including semantics, ostensive cues and contextual information (Bohn & Frank, 2019)—is essential to understanding a speaker's intentions. Despite current literature suggesting that certain social cognitive processes such as gaze-processing (Slessor et al., 2014) appear to be impaired in late adulthood, it is not well understood if pragmatic reasoning decline with age. Here, we examined young adults' (aged 19-25; $n=41$) and older adults' (aged 60-79; $n=41$) ability to engage in pragmatic reasoning in a cue integration task. In Experiment 1, participants had to integrate contextual (participants and speaker knew there were two novel objects but the latter could only see one), semantic ("There's the [novel-label]" or "Where's the [novel-label]"), and gaze (speaker looked at the mutually-visible object) cues to identify the referent (Nurmsoo & Bloom, 2008). In Experiment 2, participants received contextual and semantic cues less gaze cue. In both experiments, the target referent object for "There" and "Where" trials was the mutually-visible object and the object the speaker could not see respectively. Overall, young adults outperformed older adults, even in the simpler two-cue Experiment 2 ($ps < .006$). While older adults were significantly above chance in "There" trials for both experiments as well as "Where" trials in Experiment 2 ($ps < .05$), they had specific difficulty in integrating three cues in "Where" trials, where a more sophisticated interpretation of the multiple cues was required ($p=.42$). Our findings provide important insights into an age-related decline of pragmatic reasoning in older adults.

COMPARING WORKING MEMORY AND VERBAL LEARNING IN OLDER ADULT MUSICIANS AND NON-MUSICIANS

Caroline Galloway,¹ and Jessica Strong,² 1. *University of Prince Edward Island, University of Prince Edward Island, Prince Edward Island, Canada*, 2. *University of Prince Edward Island, Charlottetown, Prince Edward Island, Canada*

Previous research suggests that learning or playing an instrument may benefit working memory and executive functioning. The literature also suggests vocal training or singing ability may increase proficiency in verbal learning and working memory. Despite the benefits of musical training, the underlying mechanisms remain unclear. Older adult participants ($N=38$, Mean age =70.2) provided their music training history and completed a cognitive test battery. Musicians were either instrumentalists and/or vocalists ($N=24$) or non-musicians ($N=14$). Independent t test analyses were run with the current modest sample size to compare scores in basic and complex attention and working memory (Digit Span Forward (DSF) and Digit Span Backwards (DSB), and Digit Span Sequencing (DSS)), and verbal learning and memory (California Verbal Learning Test-3 (CVLT)). Results found that musicians/singers had higher scores compared to non-musicians on DSS ($t(32)=-1.96$, Cohen's $d=.72$, $p=.058$) and on CVLT delayed raw scores ($t(32)=-1.98$, Cohen's $d=.71$, $p=.056$), both with a medium-large effect size. There were no significant differences found between musicians and non-musicians in DSF and DSB or on CVLT immediate recall/learning. The results suggest that musical training, either instrumental or vocal, may contribute to working memory and

verbal memory in older adults. Both the Digit Span task and CVLT rely heavily on executive functioning ability, which may act as a mechanism or mediator between instrumental and vocal training and scores on these cognitive tasks.

DOES HBA1C INFLUENCE THE RELATIONSHIP BETWEEN STRESS AND COGNITION? FINDINGS FROM THE VA NORMATIVE AGING STUDY

Austin Brockmann,¹ Carolyn Aldwin,¹ and Avron Spiro,² 1. *Oregon State University, Corvallis, Oregon, United States*, 2. *Boston University, Boston, Massachusetts, United States*

Type 2 diabetes has increased in prevalence globally, with potential adverse effects on cognition. Both high levels of hemoglobin A1c (HbA1c) and stressful life events (SLEs) are associated with impaired cognitive performance, but few studies have examined their synergistic effects. The present study examined direct effects of stress and HbA1c on several cognitive outcomes, and whether HbA1c moderated the relationship between SLEs and cognition. Utilizing a sample of 527 older men from the VA Normative Aging Study (Mage = 74.3, SD = 6.5), stress was inversely related to MMSE, verbal fluency, and pattern recognition; HbA1c was only inversely associated with MMSE. The moderation model was supported only for pattern recognition ($\beta = 1.64$, $p < .05$), with stress having worse effects in those high in HbA1c. Stratifying analyses by age group (<75, 75+) showed that stress predicted cognition only in the young-old, while HbA1c was inversely related to cognition only in old-old participants. Further, these age-group analyses yielded different effects of demographics on cognition. In the young-old, age was consistently inversely related to all cognitive outcomes, but in the old-old only with MMSE and word list recall. Among the young-old, education was associated with only word list recall but improved performance for most scales among the old-old. Finally, HbA1c intensified the effect of stress moderation on verbal fluency only in old-old ($\beta = 2.78$, $p < .05$). In summary, stress was more important for cognition in the young-old, while education and health status were more important in the old-old.

EFFECTS OF AGE AND SELF-PERFORMANCE ON MEMORY FOR THE ACTIONS OF OTHER PEOPLE

Alan Kersten,¹ Julie Earles,² and Jennifer Brymer,² 1. *Florida Atlantic University, Boca Raton, Florida, United States*, 2. *Florida Atlantic University, Jupiter, Florida, United States*

This research tested whether performing an action themselves leads young and older adults to have difficulty remembering which of a number of other people had performed that same action. It also tested whether observing another person perform an action leads to false memory for self-performance of that action. Young adults and healthy older adults 62 to 88 years of age viewed videos of actors performing actions. After viewing some of the actions, participants were instructed to perform those same actions themselves. Participants were tested one week later on their memory for their own actions and for the actions of the actors in the videos. Older adults were more strongly influenced by self-performance than were young adults when asked whether the actor in a test item had performed the same action previously. Young adults performed better than older adults at discriminating the correct and incorrect actors in the videos, although both groups

showed reduced discrimination for actions that they had also performed themselves. The two groups were equally likely to falsely remember having performed an action that had only appeared in the videos, but young adults were better able than older adults to correctly identify the actions that they had in fact performed. Older adults thus have greater difficulty than young adults at distinguishing self-performed actions from actions performed by other people. This suggests the existence of common representations for the actions of oneself and others that must be bound to identity information to specify the correct source of the actions.

EVALUATION OF EPISODIC AND LEXICAL METAMEMORY AND EXECUTIVE FUNCTION IN HEALTHY OLDER ADULTS

Atsuko Hayashi, *Kobe University, Kobe, Hyogo, Japan*

In older adults, it is important to maintain awareness of memory as well as memory performance. However, it is not clear whether the awareness of episodic and lexical memory changes with age and is related to self-evaluation of memory and executive function. Here age-related changes and the relationship between metamemory, executive function, and metamemory scale were investigated. Healthy old ($n=40$) and young ($n=34$) groups participated in this study. In the episodic memory task, participants were asked to memorize ten Kanji words and to estimate the number of words they could recall after ten minutes. In the lexical memory task, they rated the likelihood that they could write a target Kanji word written in hiragana and then wrote them down. They were also asked to complete the metamemory in adulthood (MIA) and the position stroop task. In the episodic and lexical memory and the position stroop task and MIA subscales, the performances of the younger group were significantly better than those of the older group. In the episodic memory task, there were correlations between the metamemory and MIA subscales in both groups, but in the lexical memory task, only in the old group. No correlation was found between the results of both memory tasks and the stroop test. These results suggest that older people overestimate memory performances in the episodic and lexical memory tasks and metamemory performances may be associated with self-evaluation of memory. In addition, metamemory might not be related to frontal lobe function as shown in executive function tasks.

FRAILITY AND PROCESSING SPEED PERFORMANCE AT THE CUSP OF MIDLIFE IN CATSLIFE

Maria Luna,¹ Shandell Pahlen,² Robin Corley,³ Sally Wadsworth,³ and Chandra Reynolds,⁴ 1. *University of California, Riverside, Riverside, California, United States*, 2. *University of California, University of California, California, United States*, 3. *University of Colorado Boulder, Boulder, Colorado, United States*, 4. *University of California Riverside, Riverside, California, United States*

Frailty is an important multi-domain measure of health status and aging. Processing speed (PS) performance may be predictive of later frailty among older adults, but the interrelation between frailty and PS at the cusp of mid-adulthood is unclear. Using data from the ongoing Colorado Adoption/Twin Study of Lifespan Behavioral Development and Cognitive Aging (CATSLife; $N = 1213$;

Mean age = 33.22 years; $SD = 5.0$), we constructed a 24-item frailty sum score across anthropomorphic, objective health, and perceived health and engagement measures based on the Accumulation of Deficits model. PS was measured using the Colorado Perceptual Speed (CPS) and WAIS-III Digit Symbol (DS) tests. All mixed-effects regression models accounted for clustering among siblings, and covariates included sex, age, race, ethnicity, and educational attainment. Intraclass correlations (ICCs) [95% CI] for frailty among siblings, adjusted for sex and age, ranged from near zero for siblings in adoptive families, .13 [.08-.30] for nonadoptive siblings/fraternal (DZ) twins, and .44 [.40-.48] for identical (MZ) twins, suggesting possible heritable influences. Poorer PS performance was associated with higher frailty, but was significant for DS only (B: $DS = -0.43$, $p = .005$). Furthermore, the DS-frailty association was magnified by age (B: $DS \times Age = -0.06$, $p = .025$), suggesting that the associations between processing speed and frailty may increase with age. These findings help elucidate the interrelationship between indicators of frailty and cognitive performance for adults approaching midlife, a salient and understudied period within lifespan development.

HIGH COGNITIVE LOAD SITUATIONS WITH DIFFERENT CONVERSATION TOPICS AFFECT WALKING SPEED AND COGNITIVE COMPLEXITY

Hyeon Jung Kim,¹ Jennifer Yentes,² Dawn Venema,³ and Julie Blaskewicz Boron,¹ 1. *University of Nebraska Omaha, Omaha, Nebraska, United States*, 2. *University of Nebraska at Omaha, University of Nebraska at Omaha, Nebraska, United States*, 3. *University of Nebraska Medical Center, Omaha, Nebraska, United States*

Walking and talking on the phone are common high-cognitive-load-situations (HCLS; e.g. dual-tasks), requiring extra attentional allocation and increasing perceived stress. We explored whether two load types, 1) single-task (ST) walking or talking on a phone and 2) HCLS walking while talking on a phone, influenced walking and/or cognitive performance among young ($n=7$; age= 23.00 ± 2.08 yrs), middle-aged ($n=14$; age= 44.79 ± 7.42 yrs), and older ($n=15$; age= 74.47 ± 3.91 yrs) adults while controlling for perceived stress. Participants completed 3-minute trials of single-task walking (ST-W), single-task phone conversations with common (e.g., weather; ST-C) and uncommon topics (e.g., life experience; ST-U), and walking while talking on a phone (HCLS-C and HCLS-U). Walking speed was analyzed with $3(ST-W;HCLS-C;HCLS-U) \times 3(Age)$ ANCOVA. HCLS resulted in slower walking speed ($p < .001$). Older adults exhibited slower speed across conditions compared to young ($p = .015$). Cognitive complexity (i.e., conversational tone and words greater than six letters (SIXLTR)) on the Linguistic Inquiry and Word Count (LIWC) were analyzed with $2(Cvs.U) \times 2(STvs.HCLS) \times 3(Age)$ ANCOVAs. Older age was associated with less cognitive complexity; positive tone ($p = .014$) and SIXLTR ($p = .016$), respectively in conversations. Uncommon topics reduced positive tone ($p = .022$) and SIXLTR ($p = .003$). Effects of HCLS on tone ($p = .040$) and SIXLTR ($p = .005$) varied with age. HCLS with different conversation topics resulted in reduced walking and cognitive complexity while controlling for perceived stress. The analysis of cognitive complexity using common/uncommon conversation topics is a novel method to assess the impact of

HCLS. This research will disrupt the transformation of aging leading to a better understanding of attentional allocation and its effects on function.

INTERACTIVE EFFECTS OF AGE AND INFLAMMATION ON CHANGE IN ECOLOGICALLY-ASSESSED COGNITIVE FUNCTIONING

Christopher Engeland,¹ Erik Knight,² Martin Sliwinski,³ and Jennifer Graham-Engeland,¹ 1. *Penn State University, University Park, Pennsylvania, United States*, 2. *University of Colorado Boulder, Boulder, Colorado, United States*, 3. *The Pennsylvania State University, University Park, Pennsylvania, United States*

Inflammation has been implicated as a precursor to steeper declines in age-associated cognitive decline. Here we investigated biomarkers of peripheral inflammation [basal cytokines, stimulated cytokines (ex vivo), C-reactive protein (CRP)] as moderators of age-related changes in cognitive functioning. As part of the Effects of Stress on Cognitive Aging, Physiology, and Emotion (ESCAPE) study, participants (N = 233; 65% female; 63% Black, 25% Hispanic; 25-65 years of age) completed up to four instances of ambulatory cognitive testing per day across two weeks, over three waves of annual assessments. After each 2-week ecological momentary assessment (EMA) burst, blood was collected and assayed for inflammatory biomarkers. Performance on spatial working memory (mean Euclidean distance errors), processing speed (mean symbol search reaction time), and working memory (n-back test accuracy) tasks were averaged across all instances within an EMA burst. CRP and age interactively predicted change in spatial working memory ($B = 0.003$, [0.000, 0.005], $t(133.60) = 2.350$, $p = 0.020$) such that higher CRP at older ages (~60 years) was associated with a loss of the expected practice effects across waves; at younger ages, CRP did not relate to change in spatial working memory. In a similar fashion, basal ($B = -0.002$, [-0.004, -0.000], $t(103.26) = -2.399$, $p = 0.018$) and stimulated cytokine levels ($B = -0.002$, [-0.004, -0.000], $t(126.65) = -2.183$, $p = 0.031$) interacted with age to predict change in processing speed across waves. These results indicate that inflammation may be critically associated with changes in cognitive functioning in older mid-life adults.

INTERGENERATIONAL SOCIOECONOMIC MOBILITY AND COGNITIVE IMPAIRMENT IN CHINESE OLDER ADULTS: DOES GENDER MATTER?

Rong Fu,¹ and Yujun Liu,² 1. *Siena College, Loudonville, New York, United States*, 2. *Northern Illinois University, Naperville, Illinois, United States*

The prevalence of dementia among older adults in mainland China is projected to increase rapidly in the next few decades. This study aimed to examine the impact of intergenerational socioeconomic mobility on the risk of cognitive impairment in a cohort of Chinese older adults, with a focus on potential gender differences. Data were derived from the 2011 wave of the Chinese Longitudinal Healthy Longevity Survey. Socioeconomic mobility in this study includes three dimensions: occupational mobility, educational mobility, and residential mobility. Cognitive impairment was assessed using the Chinese version of Mini-Mental State Examination. The final sample included 6,233 older adults

aged 80 years and above. Logistic regression models were performed to assess the impact of the three dimensions of socioeconomic mobility on the risk of cognitive impairment in older men and women. For men, those with stable high occupational status across generations had the lowest risk of cognitive impairment. For women, those who received no education and lived in rural areas across generations had the highest risk of cognitive impairment. These findings lend support to the cumulative risk theory, which highlights the accumulation of risk factors that places individuals in jeopardy for negative health consequences in later life. The findings have implications for advancing supportive policies and practices related to maximizing the benefits of education and occupation for cognition in later life, especially for women in rural China.

INVOLVEMENT IN DECISION-MAKING FOR DAILY CARE AND COGNITIVE DECLINE AMONG OLDER ADULTS WHO NEED CARE IN JAPAN

Ayane Komatsu,¹ Takeshi Nakagawa,² Taiji Noguchi,² and Tami Saito,² 1. *Center for Gerontology and Social Science, Research Institute, National Center for Geriatrics and Gerontology, Obu, Aichi, Japan*, 2. *National Center for Geriatrics and Gerontology, Obu, Aichi, Japan*

Effective decision-making regarding daily care for older adults with needs could reduce the risk of dementia by preventing loss of motivation and improving care quality. However, empirical studies are scarce, particularly in non-Western countries with different socio-cultural backgrounds. By using 2-year longitudinal data of older Japanese adults aged 65 years and above who were receiving care at home, as well as of their family caregivers, we examined the association of involvement in decision-making with the onset of cognitive decline among older Japanese adults requiring care. The analysis included 219 cases of individuals with normal cognition and no missing variables at baseline and responded to the follow-up survey. An MMSE score of 23 or lower at follow-up was defined as the onset of cognitive decline. The level of involvement in decision-making was assessed by one item and dichotomized (not involved/involved). The covariates were age, gender, education, MMSE score, eligibility level for long-term care, and others at baseline. At baseline, 67.1% were 75 years or older, 58.9% were female, and 91.8% responded being "involved" in the decision-making. The incidence of cognitive decline at follow-up was 30.6%. The multivariable logistic regression analysis showed that involvement in decision-making ($OR=0.298$ [95% CI: 0.10-0.88], $p=0.029$) was negatively and significantly associated with the onset of cognitive decline. Our findings show the importance of involvement in the decision-making for daily care to reduce the risk of subsequent cognitive decline in older adults requiring care, even in a culture of familism.

IS SUSCEPTIBILITY TO DEFAULT EFFECTS ASSOCIATED WITH AGE?

Julia Nolte, and Corinna Loeckenhoff, *Cornell University, Ithaca, New York, United States*

Older adults are more likely to avoid making decisions than younger adults are. Because the underlying reasons are poorly understood, the present study investigated the

potential role of age differences in susceptibility to default effects. Defaults facilitate decision avoidance because decision makers are more likely to passively accept than to actively reject pre-selected default options. A representative lifespan sample (N = 500, Mage = 49.90, SDage = 19.34, 51% female, 67% non-Hispanic White) responded to a pre-registered online study. Participants completed one default effect task comprising two scenarios, one requiring opt-out and one requiring opt-in decisions (i.e., 15 vs. 0 pre-selected features each). Susceptibility to defaults was assessed through the discrepancy between scenarios. In addition, we collected data on known determinants of default effect compliance (i.e., perceived endowment, endorsement, ease, importance of the choice, and experience making similar choices) as well as post-decisional affect. Finally, participants responded to assessments of demographic background, personality, socioemotional and health status, and cognitive ability. Susceptibility to default effects was evident both at the individual and the group level (i.e., across and within scenarios). Unlike hypothesized, older age did not predict greater susceptibility, and older adults were less rather than more likely to endorse determinants of default effect compliance. Of the covariates assessed, only identifying as non-Hispanic White, greater perceived endorsement, and greater perceived ease predicted decision makers' susceptibility to default effects. Thus, results did not support our assumption that age differences in decision avoidance might reflect age-related increments in the acceptance of decision defaults.

MUSIC ENGAGEMENT AND EPISODIC MEMORY AMONG MIDDLE-AGED AND OLDER ADULTS: A NATIONAL LONGITUDINAL ANALYSIS

Hillary Rouse,¹ Gizem Hueluer,² Mia Torres,³ Yan Du,⁴ Kyaien Conner,⁵ and Hongdao Meng,⁵ 1. *SiteRx / University of South Florida, TAMPA, Florida, United States*, 2. *University of Bonn (Germany)*, 3. *University of South Florida, University of South Florida, Florida, United States*, 4. *School of Nursing, University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States*, 5. *University of South Florida, Tampa, Florida, United States*

Recent research suggests that engagement with particular activities, such as music, can influence age-related changes in episodic memory. However, it is unclear whether, and to what, extent music engagement is associated with the trajectory of episodic memory. The objective of this study is to examine how passive (i.e., listening to music) and/or active (i.e., singing or playing an instrument) music engagement influences episodic memory over a period of 12 years. Secondary data analysis of a sample (N=5095) of cognitively healthy adults from the Health and Retirement Study were used for this study. Linear mixed effects models were used to examine the independent effect of different levels of music engagement (i.e., low, medium, and high) on changes in performance on episodic memory tasks, while controlling for confounding factors. Compared to those with low engagement (i.e., neither listening nor singing/ playing an instrument), respondents who reported being engaged at the medium (i.e., either listening or singing/ playing an instrument) or high (i.e., both

listening and singing/ playing an instrument) level performed 0.24 (p=0.003) and 0.52 (p<0.001) points better, respectively. We found evidence that music engagement attenuated the decline in episodic memory. The findings suggest that music engagement may be a protective factor against aged-related decline in episodic memory. Therefore, music engagement may offer a promising non-pharmacological intervention for dementia risk mitigation among community-living middle-aged and older adults. Future research should examine whether interventions to increase music engagement can affect the trajectories of aged-related decline in cognition in this large and growing population.

NEUROANATOMICAL MODERATORS OF THE IMPACT OF MILD BEHAVIORAL IMPAIRMENT ON COGNITION

Hillary Rouse,¹ and Brent Small,² 1. *SiteRx / University of South Florida, TAMPA, Florida, United States*, 2. *University of South Florida, Tampa, Florida, United States*

Older adults with mild behavioral impairment (MBI), or the presence of late-life neuropsychiatric symptoms, have a unique cognitive phenotype. However, the neural correlates associated with MBI-related cognitive changes is not well understood. The goal of this study is to examine if specific regions of the brain moderate the relationship between the presence of MBI and performance on tasks of cognition. Data from the National Alzheimer's Coordinating Center was utilized for this study. Participants (N=1,451) were included in our analyses if they were cognitively healthy or had mild cognitive impairment (MCI). Multiple domains of cognitive performance were evaluated. The neuroanatomical regions included hippocampus, caudal anterior cingulate (ACC), rostral ACC, entorhinal, and parahippocampal gray matter volume; and caudal ACC, rostral ACC, entorhinal, and parahippocampal mean cortical thickness. Hippocampal, entorhinal, and parahippocampal cortical gray matter volume moderated the relationship between MBI and performance on tasks of episodic memory. Left rostral ACC cortical gray matter volume and entorhinal and parahippocampal mean cortical thickness moderated the relationship between MBI and performance on language tasks. Hippocampi cortical gray matter volume also moderated the relationship between MBI and performance on processing speed tasks. Persons with smaller brain sizes in these areas were more negatively affected in these cognitive domains if they had MBI. These results suggest that the association between smaller brain volumes and cognition was stronger among persons with MBI. These findings suggest that older adults with MBI may perform worse on these tasks due to neurodegeneration that is present.

PERSON, PLACE, AND TIME EFFECTS ON COGNITIVE FUNCTION AMONG OLDER PEOPLE IN TAIWAN

Hui-chuan Hsu, and Chyi-Huey Bai, *Taipei Medical University, Taipei, Taipei, Taiwan (Republic of China)*

Purpose: Individual's factors across time or combined with area characteristics related to cognitive function for older people have been widely explored, but little research examined person, place, and time effects altogether. The purpose of this study was to examine the effects of individuals, cities, and time on older people's cognitive function in Taiwan. Methods:

A nation-representative longitudinal individual data were from Taiwan Longitudinal Survey on Aging (TLISA) 1999-2015 panel data (analysis sample $n=6349$ persons, observations=12042). Cognitive function was scored 0-19. Individual's factors included demographics, health conditions and health behaviors, mental health and stress, social support and social participation, etc. Eleven city-level indicators were based on 22 cities and data were from the government open data sources. Mixed linear modeling analysis was applied. Results: Better cognitive function was significantly related to individuals' working, ethnicity, younger age, better education level, better self-rated health, less psychological stress, receiving more emotional support, having higher economic satisfaction at the intercept. Sex, ethnicity, age, education, self-rated health, physical function, and social connectedness were significant at the time slope. When controlling for individuals' factors, population density and green land were significant at the intercept and at the time slope. Interactions of individual- and city-level factors were not significant. Discussion: Individual's social participation and social support are protective factors of cognitive function for older adults. And an age-friendly environment providing appropriate cognitive stimulation and chances of social participation may be beneficial for cognitive function.

RACE-DISCORDANT SCHOOL ATTENDANCE AND COGNITIVE FUNCTION IN LATER LIFE

Dawn Carr, and John Reynolds, *Florida State University, Tallahassee, Florida, United States*

Early schooling plays an important role in shaping cognitive development, both due to the level of academic rigor and the social environment of primary and secondary schools. This is reflected in current racial disparities in cognitive function in later life. Older minorities who attended predominantly White schools with more resources experienced significant cognitive benefits. This study explores whether there are benefits to cognitive functioning in later life from having attended socially diverse schools in early life. We examine the effects of having attended schools composed primarily of different race peers—race discordant schools (RDS)—among Black, Hispanic, and White older adults. Using retrospective and prospective data from the Health and Retirement Study, we examine the association between RDS exposure and four measures of cognitive function (working memory, episodic memory, mental status, overall cognitive function). We assess function at age 55 and 70, and examine change in functioning between age 55 and 70. We find that RDS exposed Blacks and Hispanics experience significant benefits in cognitive function at age 55, but only Blacks experience benefits at age 70. RDS exposed Whites reported higher overall working memory at age 70 relative to Whites in non-RDS schools, suggesting a cognitive benefit from diversity. Results suggest that exposure to more racially diverse school environments have potentially beneficial effects on cognitive function over the life course. Our findings suggest that the cultivation of diversity in schools could be an important long-term public health investment.

RELATIONSHIP OF CANNABIS USE WITH IMMEDIATE, DELAYED, AND WORKING MEMORY: THE HEALTH AND RETIREMENT STUDY

Madison Maynard, Daniel Paulson, Michael Dunn, and Robert Dvorak, *University of Central Florida, Orlando, Florida, United States*

Past research has examined relationship between cannabis use and cognition among adolescents and young adults, but less is known about older adults despite rapidly increasing recreational and therapeutic cannabis use by this demographic. These relationships were explored cross-sectionally using data from the 2018 wave of the Health and Retirement Study (HRS). Dependent variables included immediate and delayed memory (10-item word list) and working memory (serial sevens; range 0-5). Cannabis use was categorized as non-user ($n=886$), past-user ($n=334$), current moderate (<52 uses/year; $n=36$), and current heavy ($52+$ uses/year; $n=92$). Mean age was 67.59 years (range: 50-98, $SD=10.76$). The sample was predominantly female (59%), and Caucasian (67%). Uncontrolled analyses found that cannabis use group was associated with immediate memory ($F=6.14$, $p<.001$), delayed memory ($F=3.75$, $p=.01$), and working memory ($F=6.91$, $p<.001$). Analyses controlled for gender, education, age, and race found that cannabis use group was no longer associated with delayed memory ($F=1.74$, $p=.16$) or working memory ($F=1.66$, $p=.17$); however, cannabis use was associated with immediate memory ($F=3.75$, $p=.01$) in controlled analyses. Current heavy users' ($M=4.94$, $SE=.16$) immediate memory worse than that of both non-users ($M=5.48$, $SE=.06$) and past users ($M=5.49$, $SE=.09$; $p<.05$ for both). Gender, education, age, and race significantly associated with immediate, delayed, and working memory, respectively ($p<.05$ for all). In conclusion, relative deficits in immediate memory, but not delayed memory or working memory, were associated with current heavy cannabis use among older adults. In combination with other findings, these results may inform development of safe-use guidelines for older adults.

TECHNOLOGY SUPPORTING COGNITIVELY IMPAIRED OLDER ADULTS: A SCOPING REVIEW FOR THE ENHANCE CENTER

Edie Sanders, Robin Stuart, Alexander Exum, and Walter Boot, *Florida State University, Tallahassee, Florida, United States*

Cognitive impairments (CIs) result in difficulties with a wide range of daily activities. Older adults are especially at risk for CIs, and as the older adult population increases, so does the importance of understanding and supporting the needs of those with CIs. The Enhancing Neurocognitive Health, Abilities, Networks, and Community Engagement (ENHANCE) Center was established with a focus on developing technology-based support for socialization, transportation, and prospective memory needs of older adults with CIs due to mild cognitive impairment (MCI), traumatic brain injury (TBI), and stroke. The extent to which relevant literature in these domains existed was unknown. We conducted a scoping review to identify existing research meeting the following criteria: participants aged 50+ years classified as having a CI due to MCI, TBI, or stroke; and a focus on technology-based support for socialization, transportation, and/or prospective memory needs. Using PRISMA guidelines, we searched three electronic databases, and reviewers screened citations for inclusion and completed data charting. Following screening, only 11 studies met our inclusion criteria. Qualitative and quantitative data are reported for each study. In addition to few studies available, it was common for studies to include 20 or fewer participants. Most assessed technology interactions at one time and few studies

examined longitudinal use and benefits. While each paper examined one aspect of user-centered design, no technologies were reported that underwent all stages of the user-centered design process, from needs assessment to iterative design and usability testing, to efficacy trial. Such gaps highlight the important role ENHANCE can play.

THE RELATIONSHIP BETWEEN RELIGIOSITY AND COGNITIVE FUNCTION AMONG CHINESE OLDER ADULTS IN CHICAGO

Jacob Koppel Egierd,¹ Stephanie Bergren,² Lisa Lanza,³ Dana Dytchwald,³ and XinQi Dong,³ *1. Rutgers University New, Monroe Township, New Jersey, United States, 2. Rutgers University, New Brunswick, New Jersey, United States, 3. Rutgers University, Rutgers Institute for Health, New Jersey, United States*

Evidence suggests religiosity may be related to cognitive decline in older adults living in the US and China. However, the relationship between religiosity and cognitive function has not been tested in a Chinese community in the US. Immigration and isolation often cause diasporas to differ from communities where they currently reside and their origin. This study aims to determine the relationship between religiosity, cognitive function, and demographic attributes in a sample of older Chinese adults age 60 to 105 living in the Chicago area (N = 3157). Regression analysis showed participation in organized religion significantly predicted higher global cognitive function ($\beta = 0.031$, $p < 0.001$, N = 3051). Of all cognitive function measures including episodic memory (East Boston Memory Immediate and Delayed Recall Test), perceptual speed (Symbol Digit Modalities Test), working memory (Digit Backwards Test), cognitive impairment (Mini Mental State Examination), and a composite measure of (global cognition), the importance of religion only significantly predicted greater working memory capacity ($\beta = 0.045$, $p = 0.003$, N = 3058). Practicing religion at home had a nonsignificant relationship with all measures of cognitive function. All analyses controlled for the following covariates: gender, education, income, number of children, marital status, and health insurance coverage status. Findings suggest that among aspects of religiosity, organized religious involvement may have a positive association with higher cognitive function. Future research should explore between-population differences in the relationships of social factors, religiosity, and cognition function to determine what practices can best benefit older adults in various communities.

TRANSCRANIAL BRAIN STIMULATION IMPROVES COGNITION IN OLDER ADULTS WITH DEPRESSION AND ANXIETY

Mathieu Figeys,¹ Esther Kim,² Ada Leung,¹ Jim Raso,³ Hubert Kammerer,⁴ David Rawani,³ and Glenrose Geriatric Research Team (Alberta Health Services),³ *1. University of Alberta, Edmonton, Alberta, Canada, 2. University of Alberta, University of Alberta, Alberta, Canada, 3. Alberta Health Services, Edmonton, Alberta, Canada, 4. Alberta Health Services, Alberta Health Services, Alberta, Canada*

Older adults admitted to hospital for rehabilitation often have some degree of concomitant cognitive impairment, which may be a barrier to optimizing rehabilitation

approaches. Transcranial direct current stimulation (tDCS), a type of non-invasive brain stimulation, delivers a low electrical current across the brain. The neuromodulatory effects of tDCS can be of therapeutic benefit and has been shown to augment cognitive functions in both healthy and clinical populations. This study investigated the effects of tDCS on cognition in older adult inpatients with depression or anxiety. It was hypothesized that anodal tDCS over the left dorsolateral prefrontal cortex would increase cognitive performance compared to a placebo group. Twenty adults between 65 to 86 years of age admitted to the Glenrose Rehabilitation Hospital with underlying depression or anxiety were recruited. Anodal (n=10) or sham (n=10) tDCS stimulation was administered at 1.5mA over 20 minutes, for 10-15 sessions based on participant availability. Cognitive assessments were administered before and after the tDCS protocol. Anodal tDCS stimulation resulted in significant gains on the Symbol Digit Modality Test, Trail Making Test Part A, and Forward Digit Span. This study demonstrated a tDCS-invoked cognitive enhancement in the domains of attention, information processing speed, and short-term memory processes. With the rapidly ageing population, tDCS may be a potential therapeutic option for cognitive enhancement and may be beneficial in ageing-related cognitive-disorders including mild cognitive impairment and dementia.

VASCULAR ILLNESS, COGNITION, AND SUBJECTIVE AGING: EXAMINING THE VASCULAR HYPOTHESIS OF AGING

Victoria Dunsmore, and Shevaun Neupert, *North Carolina State University, Raleigh, North Carolina, United States*

Cognition relates longitudinally and cross-sectionally to physical and psychological health among older adults. The Vascular Hypothesis of Aging (Drewelies & Gerstorff, 2020) suggests that illnesses of a vascular nature (e.g., stroke, hypertension, severe varicose veins) negatively affect cognitive abilities. Awareness of age-related change (AARC) is also related to cognition. What is not known is whether the presence of a vascular illness and daily cognitive abilities interact to predict daily awareness of age-related changes. The purpose of this study is to examine the daily fluctuations of cognition, (i.e., memory failures) and their interaction with vascular illness to predict daily awareness of age-related changes. Data were analyzed from 104 participants (M age = 64.67, 60-90 years) who completed online self-report questionnaires regarding presence of vascular illness, and on Days 2-9 completed measures regarding AARC losses and memory failures. Multilevel models revealed main effects of daily memory failures on awareness of age-related losses, such that on days with more memory failures, older adults reported more age-related losses. We also found a main effect for vascular illness, such that those with a vascular illness reported higher levels of daily age-related losses. We did not find a significant interaction between vascular illness and daily memory failures on daily reported age-related losses. Our results provide preliminary evidence that the vascular hypothesis of aging may also extend to perceptions of age-related changes. Future research could consider examining daily symptoms of vascular illness as they unfold over time.

VOICE BIOMARKERS AS POSSIBLE INDICATORS OF COGNITIVE AGING

Elizabeth Mahon,¹ and Margie Lachman,² 1. *Brandeis University, Waltham, Massachusetts, United States*, 2. *Brandeis University, Brandeis University, Massachusetts, United States*

There is emerging evidence that measures of voice prosody are related to diagnoses of Alzheimer's Disease and Related Disorders. The goal of this study was to examine whether voice prosody measures (pitch, pulse, voice breaks, jitter, shimmer, and amplitude) are also related to individual differences in normal cognitive aging. Data are from the Midlife in the United States Wave 2 (M2) and Wave 3 (M3) for 2693 participants (ages 42-92 at M3) who completed the M2 and M3 Brief Test of Adult Cognition by Telephone (BTACT) and had M3 voice recordings. Voice variables were measured from cognitive interviews using three cognitive tests and averaged to create a composite for each voice variable. Voice prosody was related to age, sex, education, and health, which were included as covariates. Older adults, men, and those with more health conditions had higher jitter and shimmer. Older adults, women, and those with higher education and better health had more voice breaks. Hierarchical regression models, controlling for the covariates, examined the voice composites as predictors of each cognitive measure at M3 and change over 9 years from M2 to M3. As hypothesized, higher jitter predicted lower performance and greater decline on memory, category fluency, and attention. Contrary to predictions, a lower number of voice breaks predicted worse performance and greater declines on all cognitive tests. The results suggest that voice biomarkers are related to cognitive performance and decline, and they may offer a promising approach for identifying early signs of cognitive impairment or dementia.

WHY DOES COGNITIVE RESERVE ALIGN WITH MODERN WESTERN IDEALS OF SUCCESS?

THEORETICAL & METHODOLOGICAL PROPOSALS

Douglas Hanes, *Stony Brook University, Stony Brook, New York, United States*

Cognitive reserve (CR) is a framework that investigates discrepancies between brain pathology and cognitive decline. In explaining why individuals with similar levels of brain pathology display different levels of functional impairment, CR research focuses on factors that resemble modern, Western ideals of success: greater education, professional achievement, a self-directed life, and physically and intellectually stimulating leisure time. This theoretical paper documents this alignment between CR and modern, Western ideals of success to hypothesize different mechanisms by which CR may operate. The focus in the CR literature has been on investigating and operationalizing the direct cognitive changes that come from intellectual cultivation, and the native abilities that are hypothesized to produce differences in both education and cognitive outcomes. This paper argues that an attention to CR's relationship to current definitions of success presents alternative hypotheses about the mechanisms by which CR operates. Specifically, the paper outlines two potential mechanisms and frames alternative means of studying them: First, does the accrual of CR simply follow from being successful in conventional ways because of the

material benefits of wealth and stability that success brings? Second, does a lack of success carry cognitive risks solely because of material deprivation, or are there additional psychosocial penalties that come from living a non-normative life—especially when that is not of one's choosing? This paper proposes both cross-cultural and intersectional methods to begin to better understand the relationship between normative success and cognitive health.

Session 9140 (Poster)

Cognition II

ASSOCIATION BETWEEN DIET AND COGNITIVE PERFORMANCE IN ADULTS AGED 60 AND OVER: NHANES, 2011–2014

Md Towfiquel Alam,¹ Elizabeth Vasquez,² and Sandra Echeverria,³ 1. *University of North Carolina at Greensboro, Greensboro, North Carolina, United States*, 2. *University of Albany, University of Albany, New York, United States*, 3. *University of North Carolina at Greensboro, University of North Carolina at Greensboro, North Carolina, United States*

There is limited evidence examining associations between diet and cognitive performance (CP) in older adults. We used the 2011-2014 National Health and Nutrition Examination Survey to determine if meeting dietary recommendations was associated with CP in adults 60+ years of age. Diet was based on the healthy eating index (HEI) 2015 and categorized into quintiles (higher quintiles indicating healthier diet). CP was based on word list learning, animal naming, and digit symbol substitution test, with scores above 25th percentile indicating adequate performance. Multivariate logistic regression modeling was conducted and adjusted for potential cofounders. A total of 3,068 participants completed the CP tests. A slightly higher percentage of participants were female (54.0%), predominantly White (80.5%) and the largest percentage (54.7%) was 60 to 69 years of age. The mean HEI-2015 score (0-100) was 54.89 (SE = 0.56). High CP scores increased with healthier dietary quintiles. However, results were only significant (p for trend <0.05) for digit symbol substitution test when comparing those in the highest quintile (82.53%) to those in the lowest (70.23%). Compared with participants in the lowest quintile of HEI-2015, participants in the highest quintile had a two-fold increased odds of better digit symbol substitution test scores, after adjusting for confounders (Odds Ratio [OR]: 1.96, 95% Confidence Interval [CI]: 1.28-3.01). Results showed that meeting healthy diet recommendations is associated with improved digit symbol substitution test, a marker of attention, processing speed and executive function. Future research should consider the role of diet in older adults to improve cognitive performance.

CHRONIC STRESS PATTERNS AMONG OLDER ADULTS AND ASSOCIATIONS WITH COGNITIVE FUNCTIONING

Kun Wang,¹ Zainab Suntai,¹ and Xiayu Chen,² 1. *University of Alabama, Tuscaloosa, Alabama, United States*, 2. *University of Illinois at Urbana-Champaign, New York, New York, United States*

Chronic stress has been associated with several adverse cognitive outcomes, including impaired judgement, executive functioning, and memory. Chronic stress has also been linked to several neurological conditions, including Dementia and Alzheimer's. While several biomedical measures of stress exist, stress is often subjective, and research has shown that the ability to cope with stress-known as stress reactivity-is more indicative of stress burden than the actual stressor itself. As such, this study aimed to identify the association between different patterns of stress and cognition among older adults. Data were derived from the 2016 Health and Retirement Study, a nationally representative study of older adults aged 50 and older living in the United States. Latent class analysis was used to identify different classes of stress and hierarchical linear regressions were conducted to identify the associations between identified stress classes and cognition. The latent class analysis resulted in four stress classes: high stress, financial stress, secondary stress, and low stress. The sequential logistic regression models revealed that while high stress and financial stress classes resulted in cognitive decline, the significance was mitigated after controlling for health and body functioning factors. This suggests that older adults are experiencing stressors mostly from health impairments and interventions should target improved health management and financial support for health conditions as an indirect way of reducing disparities in cognitive functioning resulting from chronic stress.

DEPRESSIVE SYMPTOMS MODERATE THE ASSOCIATION BETWEEN LIFETIME DISCRIMINATION AND INHIBITION AMONG OLDER ADULTS

Regina Wright,¹ and Desiree Bygrave,² 1. *University of Delaware, University of Delaware, Delaware, United States*, 2. *Benedict College, Benedict College, South Carolina, United States*

Discrimination has been identified as a potentially modifiable environmental stressor that reduces cognitive function. As the burden of discrimination can extend from early to late life, understanding its role in cognition in late life is critical. Further, understanding the potential moderating influence of depressive symptoms, which are common among older adults, on the linkage between discrimination and cognition, may provide further insight into the potential patterns of psychosocial stress and negative affect that may promote cognitive decline and dementia. Thus, we sought to examine whether depressive symptoms moderate linear relations of lifetime discrimination to cognitive function in the domains of visuospatial, verbal, and working memory, executive function, and psychomotor ability, adjusting for age, sex, race, and education. Participants were 165 older adults (34% male) with a mean age of 68.43y. Participants completed a health screening, a battery of cognitive tests, a psychosocial assessment, and cardiovascular testing relevant to the larger study. Linear regression results showed a significant interaction between lifetime discrimination and depressive symptoms ($p < .05$) related to the Stroop interference score, a measure of inhibition. A probe of the interaction showed that greater lifetime discrimination was associated with better inhibition among participants with fewer depressive symptoms. This paradoxical finding is consistent with

scant research that shows exposure to discrimination may heighten performance, and is more common among individuals that have achieved more, both educationally and vocationally. Greater depressive symptomatology may reduce this paradoxical association. Future research should explore this question both longitudinally and in a larger sample.

EDUCATION DIFFERENCES IN OLDER ADULTS' PERFORMANCE ON ONLINE ASSESSMENTS OF INDUCTIVE REASONING AND VERBAL MEMORY

Grace Caskie,¹ and Abigail Voelkner,² 1. *Lehigh University, Bethlehem, Pennsylvania, United States*, 2. *Lehigh University, Easton, Pennsylvania, United States*

Paper-and-pencil measures of inductive reasoning and verbal memory administered in-person are well-established methods for measuring cognitive ability in adults. However, given recent increases in the use of online surveys, particularly during the COVID-19 pandemic when in-person research with older adults became difficult, we investigated whether these cognitive measures could be administered effectively online and whether older adults' performance on these measures of inductive reasoning and verbal memory might differ by education level. Data were collected online between mid-May and mid-June of 2020 from 292 individuals aged 66-90 years ($M = 69.1$, $SD = 3.3$). The sample was primarily White (91%) and had more women (62%) than men; 83 participants had a graduate-level education (master's/doctoral degree), 101 had an associate's or bachelor's degree, and 108 had less than an associate's degree. Three measures of inductive reasoning (Number Series, Letter Sets, and Word Series) and two measures of verbal memory (Immediate Recall and Delayed Recall of a list of 20 words) were completed by participants on an online platform. One-way MANOVA found a significant main effect for education group on the inductive reasoning measures (Wilks' $\lambda = .93$, $p = .001$). However, follow-up univariate ANOVAs indicated significant differences by education group only for Number Series, with Tukey post hoc tests showing that the graduate-level and college-degree groups performed significantly better than the group with less than an associate's degree. Factorial repeated-measures ANOVA found a significant decline between immediate and delayed recall ($p < .001$) and that this difference varied by education group ($p = .003$). Implications of these findings will be discussed.

EDUCATIONAL MOBILITY THROUGH MARRIAGE AND RISK OF COGNITIVE IMPAIRMENT IN LATE LIFE

Rong Fu, *Siena College, Loudonville, New York, United States*

Objectives: Marriage represents a long-term intimate relationship involving high levels of interaction and shared resources. Education, as an inter-individual resource, may influence the health status of an individual and his/her spouse. The aim of this study was to assess the impact of educational mobility through marriage on the risk of cognitive impairment in older adults. Methods: Data were derived from the 2014 wave of the Chinese Longitudinal Healthy Longevity Survey. The final sample included 1,396 married men and 671 married women aged 65 years and older. Cognitive impairment was assessed using the Mini-Mental State Exam

(MMSE). The gender-specific effect of educational mobility on the risk of cognitive impairment was tested by logistic regression analyses. Results: Older men who experienced downward educational mobility through marriage had a higher risk of cognitive impairment, when compared to their upwardly mobile counterparts. This association was not observed in women. Having more years of schooling protected both men and women from being cognitively impaired in late life. Discussion: These findings provide further evidence that downward socioeconomic mobility through marriage is associated with adverse health outcomes. Yet, the impact of spousal education on health must be understood through the lens of gender. Potential mechanisms that may link spousal education to cognition over the life course were discussed, including health literacy, health behaviors, and household resources.

EVENT CENTRALITY OF POSITIVE AND NEGATIVE AUTOBIOGRAPHICAL MEMORIES IN OLDER ADULTHOOD

Justina Pociunaite, and Tabea Wolf, *Ulm University, Ulm, Baden-Wurttemberg, Germany*

Centrality of an event (CE) is a characteristic denoting how important a life experience is to one's identity. Usually, positive memories are more central than negative ones in the community samples. Nevertheless, there is emerging evidence showing substantial individual differences in how one perceives CE. Especially regarding age, one could expect pronounced differences due to age-related changes in personal goals. In this study, we investigated how older adults differ from young and middle-aged adults. Apart from age, we tested whether personality traits such as neuroticism and openness to experience influence the CE ratings among age groups. The sample comprised of 363 German participants, age ranging from 18 to 89 ($M=49.57$, $SD=17.087$), 67.2 % of the sample were women. Using multilevel analysis, we found the CE of positive memories to be higher in all age groups. The CE of positive events significantly differed for older adults compared to younger adults but not to the middle-aged group. With respect to personality, neuroticism had an impact only on the CE of negative memories in younger and middle-aged adults. For older adults, neither neuroticism, nor openness to experience had an impact on CE ratings. This shows that while older adults significantly differ from younger adults in the CE of positive memories, other individual differences characteristics do not have an impact on the way older adults perceive memories as central to their identity.

EVIDENCE FOR A SPECIFIC ASSOCIATION BETWEEN SUSTAINED ATTENTION AND GAIT SPEED IN MIDDLE-TO-OLDER-AGED ADULTS

Courtney Aul,¹ Hannah Park,² Joseph DeGutis,³ On-Yee Lo,⁴ Victoria Poole,⁵ Jonathan Bean,⁶ Elizabeth Leritz,¹ and Michael Esterman,⁷ 1. *VA Boston Healthcare System, Boston, Massachusetts, United States*, 2. *Brandeis University, Waltham, Massachusetts, United States*, 3. *VA Boston Healthcare System/Harvard Medical School, Boston, Massachusetts, United States*, 4. *Hebrew SeniorLife/Harvard Medical School, Boston, Massachusetts, United States*, 5. *Rush University, Chicago, Illinois, United*

States, 6. *VA Boston Healthcare System, VA Boston Healthcare System, Massachusetts, United States*, 7. *VA Boston Healthcare System/BU School of Medicine, Boston, Massachusetts, United States*

Although cognitive decline has previously been associated with mobility limitations and frailty, the relationship between sustained attention and gait speed is incompletely characterized. To better quantify the specificity of the sustained attention and gait speed association, we examined the extent to which this relationship is unique rather than accounted for by executive functioning and physical health characteristics. 58 middle-to-older-aged community-dwelling adults without overt illness or diseases (45-90 years old, 21 females) participated in the study. Each participant completed a 4-meter gait speed assessment and validated neuropsychological tests to examine various domains of executive functions including working memory (i.e., Digit Span), inhibitory control (i.e., Stroop Color Word Test), and task switching (i.e., Trail Making Test). Multiple physical and vascular risk factors were also evaluated. Sustained attention was assessed using the gradual onset continuous performance task (gradCPT), a well validated go/no-go sustained attention task. A series of linear regression models were created to examine how different aspects of cognition, including sustained attention and traditional measures of executive functioning, related to gait speed while controlling for a variety of physical and vascular risk factors. Among all predictors, gradCPT accuracy explained the most variance in gait speed ($R^2 = 0.21$, $p < 0.001$) and was the only significant predictor ($\beta = 0.36$, $p = 0.01$) when accounting for executive functioning and other physical and vascular risk factors. The present results indicate that sustained attention may be uniquely sensitive and mechanistically linked to mobility limitations in middle-to-older adults.

EXECUTIVE FUNCTIONING, EMOTION REGULATION, AND NEGATIVE EMOTION IN SUICIDAL OLDER ADULTS

Rachel Waldman,¹ Brian Liles,² Dimitris Kiosses,³ and Richard Zweig,⁴ 1. *Weill Cornell Medicine, New York, New York, United States*, 2. *Weill Cornell Medicine, White Plains, New York, United States*, 3. *Weill-Cornell Medicine, White Plains, New York, United States*, 4. *Yeshiva University, Bronx, New York, United States*

Deficits in executive functioning, emotion regulation, and negative emotion have all been linked to suicidality. Yet, the complex interactions between these three factors and their relationships to suicidal behavior in older adults remain unclear. Participants ($N = 39$) were depressed middle and older adult ($M = 62.0$, $SD = 9.41$) inpatients with recent suicidal attempt or ideation, without psychotic depression or moderate or greater cognitive impairment ($DRS > 90$). Participants were administered measures of executive functioning (Stroop and COWAT), emotion regulation (ERQ Suppression and Reappraisal; RRS-Brooding; UPPS- Premeditation Scale), and negative emotion (PANAS-X), in addition to measures of depression (MADRS) and suicidality (C-SSRS). Results indicated that executive functioning was not significantly related to emotion regulation or negative affect, but measures of emotion regulation were related to negative emotion and frequency of suicidal ideation in bivariate analyses. Lower

ERQ reappraisal tended to be associated with negative emotion ($\beta = -.392$, $p = .067$) in multivariate analyses. Although comparisons were non-significant, effect sizes revealed that those who experienced daily suicidal ideation (C-SSRS) had lower reappraisal and higher brooding scores (Cohen's $d = 1.014 - 1.456$), as well as higher executive functioning (Stroop Color-Word trial) and overall cognition (DRS) scores (Cohen's $d = 0.625 - 0.792$) than less frequent ideators. Findings suggest that older inpatients with frequent suicidal ideation have poorer emotion regulation but may have more intact cognition and executive functioning than those with less frequent suicidal ideation.

INTERGENERATION BONDING: AN ACCEPTABILITY AND FEASIBILITY STUDY

Ladan Ghazi Saidi,¹ Lauren Rezac,² and Michelle McKelvey,¹ 1. *University of Nebraska at Kearney, University of Nebraska at Kearney, Nebraska, United States*, 2. *University of Nebraska at Kearney, Kearney, Nebraska, United States*

Social isolation and loneliness are detrimental risk factors to older adult's physical and psychological well-being and quality of life. Given the current situation of the COVID-19 pandemic, social isolation has risen. Social isolation affects younger adults as well and may increase the chances of depression and anxiety. In this study, we tested the acceptability and feasibility of an Intergenerational Bonding (IGB) Program with older and younger adults. Participants include students aged 19-29 at the University of Nebraska at Kearney and older adults above the age of 60 residing in the community. First, we surveyed younger and older adults to determine their interest level in participating in an IGB Program. Both groups of participants rated their interest in different activities. The most popular activities among both groups included engaging in conversations, board games, and an exchange of skills. Neither of the groups was in favor of participating in free housing opportunities or sports-related activities. Response rates were high in young adults but low in older adults, due to lack of trust. Then, in a pilot study, we measured the feasibility and acceptability of the IGB Program. Older adults residing in independent dwellings, assisted living environments, nursing homes and members of community groups were invited to participate in the intergenerational program. Response rates of older adults were low. Further, establishing collaboration with institutions such as nursing homes was not easy despite initial interest. Building trust and working with community activity group facilitators would be beneficial in recruiting older adults.

INTERNET USE AND COGNITIVE FUNCTIONING AT THE INTERACTION OF AGE AND GENDER AMONG OLDER ADULTS

Kun Wang,¹ Zainab Suntai,¹ and Xiayu Chen,² 1. *University of Alabama, Tuscaloosa, Alabama, United States*, 2. *University of Illinois at Urbana-Champaign, New York, New York, United States*

The positive relationship between internet use and cognition has long been documented in the gerontology literature, and researchers are consistently finding that internet use engages the brain in a way that improves cognitive functions

such as multitasking, information processing and executive thinking. While there are numerous studies examining this association, few studies have explored the three-way interaction between age, gender, and internet use on cognition. This study aimed to examine the gendered moderation effect of age on the relationship between internet use and cognition among older adults. The study sample was derived from the 2016 Health and Retirement study, which is a biennial longitudinal panel study of adults aged 50 and older in the United States. Multilinear regression models were used to examine the three-way interaction of age, sex and internet use on cognition while controlling for other covariates. Results showed that women gained a greater increase in cognition as a result of internet use as they became older, while men had the same amount of increase in cognition as a result of internet use regardless of age. This indicates that internet use can be a positive agent in improving cognition among older adults regardless of age and sex, and interventions should focus on increasing internet use among older adults, to ensure equitable access to the benefits of internet use on cognition.

MIND-BODY PRACTICE, PERSONALITY TRAITS, AND COGNITIVE PERFORMANCE: A 10-YEAR STUDY IN US ADULTS

Kallol Kumar Bhattacharyya,¹ Gizem Hueluer,² and Debra Dobbs,³ 1. *School of Aging Studies, University of South Florida, Tampa, Florida, United States*, 2. *University of Bonn (Germany)*, 3. *University of South Florida, School of Aging Studies, University of South Florida, Florida, United States*

It is widely established that physical activity is associated with better cognitive outcomes, and accumulating evidence suggests that mind-body practice (MBP) may yield similar benefits. Personality is related to both daily activities and cognition, but its role in the association between MBP and cognition is not well understood. The current study examines bidirectional temporal associations between personality traits, MBP, and cognition in healthy adults. We used data from waves 2 and 3 (2004-2014) of the Midlife in the United States (MIDUS) study from a total of 2,050 individuals (age: $M=64$ years, $SD=11$, range=42 to 92; 56% women). We applied a cross-lagged regression analysis to examine bidirectional effects between MBP, Big Five personality traits, and two cognitive domains (episodic memory and executive function) and controlled for sociodemographic factors, health, and functional status covariates in wave 2. After controlling for covariates, MBP was independently associated with a more favorable change in episodic memory, but not in executive function. Regarding cross-lagged effects of cognitive function, episodic memory was related to subsequent MBP and agreeableness, and executive function was related to subsequent MBP, openness, and conscientiousness. Agreeableness had a negative effect on subsequent executive function. The findings point toward bidirectional associations between cognitive function MBP, while there was no evidence for cross-lagged associations between personality and MBP. Future research should guide us whether MBP can counteract cognitive decline as an alternative and complementary practice and the role that personality can play in such interventions.

MODIFIABLE LIFESTYLE FACTORS ASSOCIATED WITH COGNITIVE RECOVERY FROM MCI: A 12-YEAR LONGITUDINAL STUDY

Bingyu Li, *Shenzhen University, Shenzhen, Guangdong, China (People's Republic)*

Introduction: Many studies have investigated the risk factors associated with progression from mild cognitive impairment (MCI) to cognitive impairment, while it is unclear which lifestyle factors are associated with cognitive recovery among those who have mild cognitive impairment. **Methods:** The study includes 7,422 participants above 65 years old with MCI from The Chinese Longitudinal Healthy Longevity Survey (CLHLS). Cox regression analysis was adopted to investigate the association between cognitive recovery and selected lifestyle factors. LASSO was applied to select the variables. **Results:** Daily consumption of fresh fruits is associated with higher possibility of cognitive recovery (HR: 1.28, 95% CI: 1.15-1.42) while daily consumption of meat show opposite influence (HR: 0.90, 95% CI: 0.80-0.99). Smoking (HR: 0.99, 95% CI: 0.98-1.00) and alcohol consumption (HR: 1.00, 95% CI: 0.99-1.00) are both negatively associated with cognitive recovery. Daily engagement in reading (HR: 1.24, 95% CI: 1.00-1.54), housework (HR: 1.21, 95% CI: 1.08-1.35) as well as mahjong and other card games (HR: 1.23, 95% CI: 1.08-1.39) are associated with higher possibility of cognitive recovery. **Conclusion:** This study has identified important modifiable lifestyle factors associated with natural cognitive recovery from MCI. The findings have considerable implications for dementia prevention.

MULTITASKING IN OLDER ADULTS' DAILY ACTIVITIES: A PRELIMINARY INVESTIGATION

Abigail Stephan,¹ Junyan Tian,² and Lesley Ross,¹ *1. Clemson University, Clemson, South Carolina, United States, 2. Penn State University, State College, Pennsylvania, United States*

The ability to multitask, defined as conducting two or more activities simultaneously, is important in daily life. The majority of prior work has examined multitasking in laboratory settings. However, less is known about how multitasking in daily activities is related to older adults' executive functioning and perceptions of aging. The current study investigated these relationships in a sample of 33 older adults aged 65-81 ($M=70.0$, $SD=3.6$). Participants were asked to describe activities they did each day and estimate time spent in each activity across fourteen days; multiple activities reported in the same time frame were considered multitasking. Executive function was measured at baseline using the Trail Making Test Part B (TMTB), with higher scores indicating worse performance. Expectations regarding aging were measured at baseline using the Expectations Regarding Aging (ERA-12) survey, with higher scores indicating more positive perceptions. Twenty-seven participants (81.82%) reported at least one instance of multitasking in the fourteen-day period. Participants were divided into three groups based on the median number of reported multitasks: no multitasking ($n=6$), low multitasking (≤ 4 ; $n=15$), and high multitasking (> 4 ; $n=12$). Although there were no significant differences within the ANOVA, participants who reported low multitasking trended towards poorer executive function and more positive expectations of aging ($M_TMTB=100.28$, $M_ERA=$

64.88) than both no multitasking ($M_TMTB=82.12$, $M_ERA=50.46$) and high multitasking groups ($M_TMTB=94.90$, $M_ERA= 54.29$). Additional research should investigate these possible relationships in larger samples and explore how covariates, such as gender and age, may moderate possible relationships.

MUSICAL EXPERIENCE RELATES TO FUNCTIONAL CONNECTIVITY IN OLDER ADULTS

Meishan Ai,¹ Timothy Morris,² Laura Chaddock-Heyman,³ Psyche Loui,² Susan Whitfield-Gabrieli,² Charles Hillman,² Edward McAuley,⁴ and Arthur Kramer,² *1. Northeastern University, Brookline, Massachusetts, United States, 2. Northeastern University, Boston, Massachusetts, United States, 3. University of Illinois at Urbana-Champaign, Urbana, Illinois, United States, 4. University of Illinois at Urbana-Champaign, Boston, Massachusetts, United States*

Previous studies have shown that engaging in musical activities throughout the lifespan may buffer age-related decline in auditory and motor function, as well as in general cognitive function. MRI studies have demonstrated that individuals with musical training and experience exhibited greater grey matter volume and functional connectivity in extensive brain regions, especially in auditory and motor systems, compared to matched controls with no particular musical training or experience. Therefore, musical activity is a potential protective factor for brain health across lifespan. However, how lifespan musical experience shapes functional connectivity in older adults is still unknown. The current analysis investigated whether general musical experience (Goldsmith Music Sophistication Index) is associated with functional connectivity in older adults ($age=65.7\pm 4.4$, $n=69$), focusing on seed regions in primary motor areas (bilateral precentral gyrus) and primary auditory regions (bilateral anterior/posterior superior temporal gyrus) and their functional connectivity towards other areas throughout the whole brain. We found that older adults with more musical experience showed greater functional connectivity between anterior superior temporal gyrus and insula ($R^2=0.10$, $p=0.01$), and between posterior superior temporal gyrus and cerebellum ($R^2=0.08$, $p=0.02$). However, musical experience and music-related functional connectivity was not significantly correlated with general cognitive functions in our sample. Overall, our findings suggest that older adults with more musical experience might be more efficient in some aspects of auditory processing and auditory-motor skills, but this may not transfer towards domain-general cognitive tests. Our results support the notion that even non-professional engagement in musical experiences may afford benefits to the aging brain.

PERCEPTUAL VERSUS CONCEPTUAL VALUE-DIRECTED STRATEGIC PROCESSING IN YOUNGER AND OLDER ADULTS

Lydia Nguyen,¹ Elizabeth Lydon,² and Raksha Mudar,³ *1. iN2. L, Denver, Colorado, United States, 2. University of Illinois Urbana-Champaign, Champaign, Illinois, United States, 3. University of Illinois-Urbana Champaign, Champaign, Illinois, United States*

Value-directed strategic processing involves selectively attending to and processing information deemed more important while ignoring or inhibiting less important information. What

we selectively attend to can be driven by the value we ascribe to the information, often based on stimulus factors such as perceptual features that make the information stand out, or conceptual features that make it easy to group information. The current study investigated whether behavioral measures of value-directed strategic processing are differentially affected when value is defined by perceptual versus conceptual features, and how normal cognitive aging impacts processing. Cognitively normal younger ($N = 16$; mean age: 22.1 ± 2.9 years) and older adults ($N = 16$; mean age: 66.9 ± 7.3 years) completed two value-directed strategic processing tasks, where value was defined by either perceptual (i.e., uppercase and lowercase letters; Letter Case task) or conceptual (i.e., animals and household items; Categories task) features. Both groups had higher recall on the Categories task compared to the Letter Case task, and higher recall for high-than low-value words. However, older adults recalled fewer total words than younger adults, but the groups did not differ across task types. These findings indicate that manipulating perceptual and/or conceptual features to define value can be used to study value-directed strategic processing in younger and older adults. Furthermore, grouping information based on conceptual features may be more effective for promoting subsequent recall in both younger and older adults.

PHYSICAL ACTIVITY AND EPISODIC MEMORY: AN ANALYSIS OF LONGITUDINAL ASSOCIATIONS OVER 12 YEARS

Rio Tate,¹ and Gizem Hueluer,² 1. *University of South Florida, Tampa, Florida, United States*, 2. *University of Bonn (Germany)*

With the increasing prevalence of Alzheimer's and related dementias, it is becoming a growing public health concern to identify modifiable risk factors to prevent cognitive decline. Previous research suggest that physical exercise may promote cognitive function in aging. However, most of this research is based on experimental or cross-sectional studies and fewer studies have studied longitudinal associations over longer time frames. In the present study, we examined how physical activity is related to cognition in older adults. To do so, we applied multilevel models to data from 29,740 participants (age at baseline: $M = 63$ years, $SD = 11$ years, 50 to 102 years) from years 2004-2016, measured biennially (waves 7-13) of the Health and Retirement Study. Our findings showed that at the between-person level, those who practiced light, moderate, and vigorous- physical activity more frequently than others showed higher levels of episodic memory than others at the age of 70. At the within-person level, participants performed better than usual on a test of episodic memory on occasions when they reported more frequent physical activity of light, moderate and vigorous intensity. More frequent vigorous physical activity was related to less age-related decline in episodic memory, while the frequency of moderate physical exercise was unrelated to age-related change in memory. Contrary to our expectations, more frequent light physical exercise was related to more age-related decline in episodic memory. We discuss the implications of these findings for future research and practice.

RACIAL AND ETHNIC DIVERSITIES IN COGNITIVE HEALTH APPRAISALS: FINDINGS FROM THE HCAP

Yuri Jang,¹ Eunyoung Choi,² Yujin Franco,³ Nan Sook Park,⁴ David Chiriboga,⁴ and Miyong T. Kim,⁵

1. *University of Southern California, Los Angeles, California, United States*, 2. *University of Southern California, LA, California, United States*, 3. *University of Southern California, University of Southern California, California, United States*, 4. *University of South Florida, Tampa, Florida, United States*, 5. *University of Texas at Austin, Austin, Texas, United States*

The aims of the study were: (1) to investigate the relationship between cognitive performance and cognitive health appraisals across non-Hispanic White, non-Hispanic Black, and Hispanic older adults in the United States and (2) to explore within-group variations by examining interactions between cognitive performance and background and health variables. The sample ($N = 3,099$) included 2,260 non-Hispanic White, 498 non-Hispanic Black, and 341 Hispanic adults aged 65 or older, from the 2016-2017 Harmonized Cognitive Assessment Protocol. Regression models of cognitive health appraisals, indicated by self-rated cognitive health, were examined in the entire sample and in racial and ethnic subgroups to test direct and interactive effects of cognitive performance, indicated by the Mini-Mental State Examination (MMSE). The regression model for the entire sample showed direct effects of cognitive performance and race/ethnicity on cognitive health appraisals, as well as a significant interaction between cognitive performance and being non-Hispanic Black. Cognitive performance and cognitive health appraisals were positively associated in non-Hispanic Whites but not significantly associated in non-Hispanic Blacks. Our subsequent analysis within each racial/ethnic group showed that the effect of cognitive performance in non-Hispanic Blacks and Hispanics became either reversed or nonsignificant when background and health variables were considered. Modification by age or chronic medical conditions in each racial and ethnic group was also observed. Overall, these findings suggest that perceptions and appraisals of cognitive health vary by race and ethnicity and hold implications for how these differences should be considered in research and practice with diverse groups of older adults.

RETIREMENT AGE MODIFIES THE ASSOCIATION BETWEEN EDUCATION/OCCUPATION AND COGNITION

Monica Nelson,¹ and Ross Anzel,² 1. *University of South Florida, Brandon, Florida, United States*, 2. *University of South Florida, Tampa, Florida, United States*

Introduction: According to the cognitive reserve and use-it-or-lose-it hypotheses, engagement in stimulating activities seems to benefit cognition, with engagement often associated with more education or higher occupational position. However, whether retirement may modify the association between education/occupation and cognition is unclear. We aimed to assess how age at retirement may modify the relationship between education/occupation and cognition. Methods: Older adults ($n=360$) from the Alzheimer's Disease Neuroimaging Initiative who were cognitively normal and retired at baseline participated. Linear regression was used to assess how educational attainment (high/low) or occupational position (managerial, intermediate/clerical, routine/manual) related to executive functioning (EF) or memory, controlling for age, sex, depressive symptoms, and health status. Effect modification by retirement (early, on-time, late). Results: High education (EF: $b=0.37$, $SE=0.08$, $p<.001$; memory: $b=0.22$, $SE=0.05$, $p<.001$), intermediate (EF:

$b=0.26$, $SE=0.11$, $p=.019$; memory: $b=0.18$, $SE=0.08$, $p=.018$) and managerial (EF: $b=0.23$, $SE=0.12$, $p=.045$; memory: $b=0.16$, $SE=0.08$, $p=.045$) occupations (compared to routine/manual occupations) were associated with better EF and memory performance. High education was significantly associated with better EF and memory for participants who retired early (EF: $b=0.43$, $SE=0.12$, $p<.001$; memory: $b=0.29$, $SE=0.10$, $p=.004$) or on-time (EF: $b=0.51$, $SE=0.15$, $p=.001$; memory: $b=0.24$, $SE=0.10$, $p=.014$), but not for participants who retired late (EF: $b=0.19$, $SE=0.15$, $p=.200$; memory: $b=0.09$, $SE=0.09$, $p=.334$). Intermediate occupations were associated with EF only for participants who retired on-time ($b=0.58$, $SE=0.21$, $p=.007$). Conclusion: Education and occupational position may influence cognition after retirement differently based on retirement timing, with effects most apparent for on-time retirement and substantially reduced for late retirement.

SEX DIFFERENCES IN SPEECH AND HIGH-FREQUENCY HEARING LOSS ASSOCIATION WITH COGNITIVE IMPAIRMENT AMONG OLDER ADULTS

Wang Jingru, Yu Ying, and Guo Qi, *Shanghai University of Medicine and Health Sciences, Shanghai, Shanghai, China (People's Republic)*

Objectives: The purpose of this study was to investigate the relationship between speech-frequency hearing loss (SFHL), high-frequency hearing loss (HFHL), and cognitive impairment (CI). Then to determine whether there are any differences in gender among older community dwellers in China. **Methods:** This study involved 1,012 adults aged ≥ 60 years (428 male; average age, 72.61 ± 5.51 years). The participants had their hearing and cognition measured using pure tone audiometry and Mini Mental State Examination (MMSE), respectively. We used the audiometric definition of hearing loss (HL) adopted by the World Health Organization (WHO). Speech-frequencies were measured as 0.5 kHz, 1 kHz, 2 kHz, and 4 kHz; high-frequencies were measured as 4 kHz and 8 kHz. Pure tone average (PTA) was measured as hearing sensitivity. **Results:** Our studies demonstrated a 37.6% prevalence of HL in males and a 36.0% prevalence of HL in females. Adjusted for confounding variables, the results from a multivariate analysis showed that SFHL was associated with CI in females (OR=2.400, 95% Confidence Interval=1.313–4.385) and males (OR=2.189, 95% Confidence Interval=0.599–2.944). However, HFHL was associated with CI only in females (OR=2.943, 95% Confidence Interval=1.505–5.754). HL was associated with poorer cognitive scores ($P<0.05$). “Registration” ($P<0.05$) in MMSE was associated with speech and high-frequency hearing sensitivity. **Conclusion:** The associations between HL and CI varied according to gender in older community-dwellers, suggesting that different mechanisms are involved in the etiology of HL. Moreover, hearing sensitivity was negatively associated with cognition scores; therefore, early screening for HL and CI among older community-dwelling adults is advised.

TELEPHONE-BASED WORD LIST RECALL AND HEARING ABILITY

Taylor Atkinson, and Ross Andel, *University of South Florida, Tampa, Florida, United States*

Certain consonant sounds called fricatives (e.g., “s” and “f”) are difficult to hear over the telephone; phones exclude high-frequency sounds that affect their intelligibility. This may be problematic for older adults responding to phone-based memory tests. Many older adults have some degree of hearing loss, and older men have it more in the high-frequency range. Hearing loss, in combination with phone bandwidth restrictions, may reduce older adults’ recall of fricative words. Participants ($n=3,612$, mean age=64.2, 60% women) in the 1998 wave of the Health and Retirement study (HRS) completed a word list immediate recall task over the phone. List 4 recall was examined because it was evenly split (5 each) between words with and without fricative consonant sounds. Subjective ratings of hearing and health, age, depression, and education were also measured. A Wilcoxon signed-rank test showed participants recalled fewer fricative ($M=2.8$) than nonfricative ($M=3.0$) words, $Z=-8.47$, $p<.001$. An ordinal regression for fricative word recall indicated a sex by hearing interaction; males with worse hearing were less likely to recall more fricative words, OR=.94, 95% CI [.88, 1.01], $p=.076$, after controlling for age, education, health, and depression. An ordinal regression for nonfricative word recall did not show a main effect for hearing or a hearing by sex interaction. For both models, age, education, and health were related to recall. Consonant sounds may influence phone-based word recall, particularly for older men. Attention should be paid to word selection when designing phone-based cognitive tests in order to avoid memory impairment overestimation.

THE EFFECT OF CHILDHOOD EMOTIONAL ADVERSITY AND LATER LIFE FRIEND SOLIDARITY ON COGNITION

Kaleena Odd,¹ Julie Blaskewicz Boron,¹ Nicholas Turiano,² and Jonathan Santo,¹ 1. *University of Nebraska Omaha, Omaha, Nebraska, United States*, 2. *West Virginia University, Morgantown, Virginia, United States*

Early life experiences can influence later life outcomes such as physical, mental, and cognitive health. Previous research investigated the effect of childhood socioeconomic status in relation to mid-to-later life cognition (Liu & Lachman, 2019); however, the effects of childhood emotional adversity on cognition have not been examined. Controlling for age, education, sex, and race, the current study investigated the influence of childhood emotional adversity and later life friend solidarity on change in later life episodic memory, executive functioning, and subjective memory (i.e., perceived memory compared to others same age). Utilizing the Midlife in the United States (MIDUS) database, we studied 2,752 participants (50–75 years, $M=60.09$, $SD=6.97$, 53% female, 84% White) with completed measures on MIDUS 1 retrospective childhood adversity, MIDUS 2 friend solidarity, and MIDUS 2/3 cognition. Multilevel modeling (Mplus) was used. Higher friend solidarity was associated with higher executive functioning ($b=0.122$, $p<.01$) and higher subjective memory ($b=0.267$, $p<.001$), suggesting the positive impact of supportive friendships. Higher childhood emotional adversity was associated with lower perceived subjective memory ($b=-0.037$, $p<.05$). There was no significant friend solidarity by emotional adversity interaction. Together, these findings suggest that later life friend solidarity may be important

for objective and subjective cognition; whereas, childhood emotional adversity may play a role in subjective cognition. Given the associations in prior research between lower perceptions of memory and lower mental well-being and quality of daily life, experiencing childhood emotional adversity may increase risk of lower perceptions of well-being, including cognitive functioning.

Session 9145 (Poster)

Cognition, Cognitive Impairment, and Brain Injury

DOES COGNITIVE STATUS MODERATE THE RELATIONSHIP BETWEEN ENVIRONMENTAL FACTORS AND SELF-REPORTED HEALTH?

Ethan Siu Leung Cheung,¹ and Ada Mui,² *1. Columbia University, New York, New York, United States, 2. Columbia University, COLUMBIA UNIVERSITY, New York, United States*

Using data from NHATS Round 9, the present study examines the relationships between environmental factors and self-reported health among older adults with dementia, mild cognitive impairment (MCI), and normal cognition. Based on neighborhood stress process theory, we investigate the following questions: 1) Are there associations between dwelling safety hazards and neighborhood environments and self-reported health? 2) Is cognitive status a moderator between the relationship? 3) How do these associations differ between older adults with varying cognitive status (i.e., dementia, MCI, and normal cognition)? A hierarchical linear regression analyses are conducted. Results indicate that better quality of sidewalk surface and neighborhood social cohesion are associated with better self-reported health, after taking into account sociodemographic, health, and social factors. Interaction terms are then used to examine the moderating effects of cognitive status on the associations; four interactions terms are found to be statistically significant. Lastly, separate linear regression analyses are implemented for the dementia, MCI, and normal cognition groups. Findings show that the predicting power of environmental factors vary by cognitive status of older adults. For individuals with dementia, tripping hazards, cluttered home, and community disconnectedness are associated with poor self-reported health. However, no significant relationship was found for older adults with MCI. For older adults with normal cognition, better quality of sidewalk surface and neighborhood social cohesion predict better self-rated health scores. Findings of this study illuminate the important role of a hazard-free home, community walkability, and socially cohesive neighborhood environments in predicting better health status of older adults.

EMPLOYERS' RESPONSE TO WORKERS WITH PROGRESSIVE COGNITIVE IMPAIRMENT: A REVIEW OF POLICY IN CANADA

Josephine McMurray,¹ Kristina Kokorelias,² AnneMarie Levy,¹ Krista James,³ Logan Reis,⁴ Jennifer Boger,⁴ and Arlene Astell,⁵ *1. Wilfrid Laurier University, Waterloo, Ontario, Canada, 2. Sunnybrook*

Research Institute, Toronto, Ontario, Canada, 3. British Columbia Law Institute, Vancouver, Ontario, Canada, 4. Waterloo University, Waterloo, Ontario, Canada, 5. University of Toronto, Toronto, Ontario, Canada

Longer lifespans, the gig economy, eligibility for government pensions, and more testing for age-related cognitive changes, increase the potential for workers developing mild cognitive impairment and/or early onset dementia (MCIEOD) "on the job". This critical analysis assesses Canada's policy environment for employers when employees are diagnosed with MCIEOD. Our search for policy literature included: a scoping review of academic literature involving Canadian-focused articles, and countries where novel or innovative policy had been evaluated and published; a search for Canadian court judgements and tribunal decisions; and a grey literature search in both Canadian and international sources, as innovation will often happen "at the margin" and updated policy may take years to be enacted and formalized. We used participatory research to obtain feedback from a broad group of stakeholders including employers, industry, professional organizations, and government, as well as people living with MCI/dementia, to ensure outputs were reflective of current policy. We found that: 1) Canadian federally-regulated employers are governed by similar Acts & Codes as the provinces and territories, with some notable exceptions, 2) Disability discrimination and accommodation case law in Canada is settled, however there are few cognitive impairment cases to provide specific guidance, 3) Scant empirical research in the scientific literature addresses policy that incents employers to build workspaces for employees with MCIEOD that help them stay on the job longer. We conclude that engaging with employers to better understand their needs will help policy-makers to support them build workspaces that encourage productive engagement of all workers.

EMPLOYERS' RESPONSE TO WORKERS WITH PROGRESSIVE COGNITIVE IMPAIRMENT: A SYSTEMATIC LITERATURE REVIEW

Josephine McMurray,¹ AnneMarie Levy,¹ Logan Reis,² Kristina Kokorelias,³ Jennifer Boger,² and Arlene Astell,⁴ *1. Wilfrid Laurier University, Waterloo, Ontario, Canada, 2. Waterloo University, Waterloo, Ontario, Canada, 3. Sunnybrook Research Institute, Toronto, Ontario, Canada, 4. University of Toronto, Toronto, Ontario, Canada*

An aging workforce increases the risk of workers experiencing cognitive decline that may lead to a diagnosis of mild cognitive impairment or early onset dementia (MCIEOD) while still employed. This systematic review explores the use of technologies (defined as any methods, processes, software, hardware or equipment) deployed by employers to accommodate, or build sustainable workspaces for, workers diagnosed with MCIEOD. After screening 3,860 titles/abstracts and 67 full text reviews, we identified and analyzed eight articles that met our inclusion criteria. We found that: 1) The existing literature almost exclusively focuses on employees' perspectives on the quality of work life when diagnosed with MCIEOD, 2) Negative workspace culture toward employees' cognitive decline, and the variability of disease onset and progression, may account for low employer awareness, 3) Employer responses focus on mitigation of risk associated

with workers' impairment. While this review demonstrates there is scant research exploring employers' perspectives on employees diagnosed with MCIEOD, there is even less that explores technologies designed to specifically address employers' needs and challenges. Technology will increasingly facilitate early identification of progressive neurocognitive disorders, and tools to help employers respond to an employee's MCIEOD disclosure as a disability accommodation rather than a terminal performance management challenge. Empathic research, that engages organizations in the process of understanding the value of affordable, employer-side technologies that help build diverse, sustainable, productive workspaces is critical to a foundational understanding of our aging workforce and accommodating workers who develop MCIEOD while still employed.

GENDER DIFFERENCE IN UNMET NEEDS AMONG PEOPLE AGING WITH A TRAUMATIC BRAIN INJURY Kelli Barton, and Emma Swinford, *University of Missouri-Kansas City Institute for Human Development, Kansas City, Missouri, United States*

Traumatic Brain Injury (TBI) can result in a myriad of short and long-term mental and physical changes and conditions. While fall-related brain injury prevention strategies and outcomes among older adults have been well-documented in previous literature, less is understood about the experiences and needs of those aging with a brain injury. The aim of this project is to explore gender differences in experiences and needs among people aging with a TBI. A Needs Assessment survey was conducted in early 2020 with adult TBI survivors and their family members in Missouri (n = 150). The mean age of respondents was 45.8 and 58% identified as male. Bivariate analyses reveal gender difference in unmet needs related to information and referral, recreation, and continuing education among TBI survivors. For example, more female respondents (43.1%) identified unmet needs associated with physical activity than their male counterparts (25.9%, $p < .05$). More females (61.3%) than males (43.4%) also identified unmet continuing education needs related to aging with brain injury ($p < .05$), whereas more males (10.8%) identified unmet continuing education needs on the topic of parenting (females: 1.6%, $p < .05$). Significantly more females (31.1%) than males (16.9%) identified lack of transportation as a barrier to accessing needed supports and resources ($p < .05$). Results will guide development of an Annual State Action Plan to maximize the independence, well-being, and health of Missourians aging with TBI and their families. A better understanding of needs and preferences can inform targeted policies, programs, and resources.

GENDER DIFFERENCES IN MENTAL AND PHYSICAL HEALTH: IMPLICATIONS FOR AGING WITH A TRAUMATIC BRAIN INJURY

Emma Swinford, *University of Missouri-Kansas City Institute for Human Development, Kansas City, Missouri, United States*

Traumatic Brain Injury (TBI) is a major cause of disability and death in the U.S., and survivors often experience temporary or life-long health effects as a result of their injury. While risks and outcomes of fall-related TBI in older adults have been well-documented, the intersection of TBI-related

health challenges and the experience of aging with a TBI is less well understood. This project explores gender differences in health outcomes among TBI survivors. A Needs Assessment survey was conducted in early 2020 with adult TBI survivors in Missouri (n=150). The mean age of respondents was 46 and 58% identified as male. Bivariate analyses reveal gender differences in health conditions among TBI survivors before and after injury. Significantly more males than females reported substance use disorder for alcohol (20.7% and 7.9%, $p < .05$) prior to injury, whereas twice as many females reported developing chronic pain after injury than males (68.3% and 31.0%, $p < .001$). Further, while about 21% of both male and female respondents reported experiencing other mental health conditions, such as anxiety, prior to injury, over 35% of males and almost 58% of females experienced mental health concerns after injury. Additionally, balance/mobility issues, sleep disorders, sensory issues, and cognitive challenges were frequently identified post-injury conditions. Co-morbidities impact our experiences, capabilities, and quality of life as we age. Policies and programs to support TBI survivors and their families may better address the co-occurring health conditions among TBI survivors by considering gender differences in the experience of aging with a TBI.

GUARDIANSHIP AND SELF-SOVEREIGN IDENTITY: IMPLICATIONS FOR PERSONS LIVING WITH DEMENTIA

Noelannah Neubauer, and Lili Liu, *University of Waterloo, Waterloo, Ontario, Canada*

Self-sovereign identity (SSI), an identity management system where individuals own and manage their digital identity, can improve access and management of one's personal data. SSI is becoming feasible for the general public to use for their health and other personal data. Like any data system, when persons living with dementia no longer have capacity to provide informed consent, guardianship over their data is required. The purpose of this study was to examine the concept of guardianship within the context of SSI, specifically its application to persons living with dementia. This study followed a qualitative description approach. Seventeen semi-structured virtual interviews were conducted with persons living with dementia and care partners to elicit their perspectives on existing guardianship practices and guardianship within the context of SSI. Interviews were digitally recorded and transcribed verbatim. Conventional content analysis guided the analytic process. Participants had mixed impressions of existing guardianship practices. While some were positive, others thought existing practices failed to consider the complexity of caring for someone with dementia (e.g., presence of multiple guardians). Participants suggested that SSI has the potential to improve the security and safety of persons living with dementia who have had guardianship enacted (e.g., reduced risk of financial abuse.) Recommendations included ensuring that SSI guardianship processes are simple and flexible, building a user-friendly system that also considers the heterogeneity of persons living with dementia and their care partners. Overall, guardianship within the context of SSI was well received. Findings will be used to further inform the SSI guardianship processes.

MARGINAL EFFECTS OF MULTIPLE YEARS OF VOLUNTEERING ON OBJECTIVE AND SUBJECTIVE MEASURES OF COGNITION

Yi Wang,¹ Takashi Amano,² Roger Wong,³ and Huei-wern Shen,⁴ 1. *University of Iowa, Iowa City, Iowa, United States*, 2. *Rutgers University-Newark, Newark, New Jersey, United States*, 3. *SUNY Upstate Medical University, Syracuse, New York, United States*, 4. *University of North Texas, Denton, Texas, United States*

Volunteering is conducive to older Americans' physical and mental health; however, the effect of volunteering on cognitive health is less studied. Using four waves (2010-2016) of the Health and Retirement Study, this study examined the incremental effect of volunteering engagement on older adults' cognitive health. We included 10,718 cognitively unimpaired, community-dwelling individuals aged 51+ in 2010 and were alive through 2016. Volunteering engagement was measured by the number of times respondents participated in volunteering throughout the four waves. Objective cognition was assessed using the Telephone Interview for Cognitive Status (TICS), a standardized test of cognitive functioning. The TICS score was further categorized into three statuses: "No impairment," "Cognitive impairment no dementia (CIND)," and "Dementia." Subjective cognition referred to self-rated memory on a 5-point Likert scale. With sampling weights, ordered logit regression was performed controlling for health-related variables (e.g., health conditions, depression), SES (e.g., income, assets), contextual features (e.g., neighborhood safety, urbanicity), and sociodemographics. The average marginal effects (AMEs) were produced. Results show that more volunteering engagement significantly reduced the likelihood of CIND or dementia (OR=0.88, $p < 0.001$). Specifically, every one-time increase in volunteering increased the probability of remaining cognitively normal by 0.01 ($p < 0.001$), whereas it decreased the probability of CIND by 0.008 ($p < 0.001$) and dementia by 0.001 ($p < 0.001$). For subjective cognition, there was no significant relationship with volunteering. Our findings address gaps in literature by adding evidence of the incremental health benefits of volunteering on cognitive functioning. Differences in the findings for subjective and objective cognition warrant further investigation.

SOCIALLY RELEVANT APPROACHES TO THE DETECTION OF DEMENTIA IN MINORITY OLDER ADULTS

Lana Sargent,¹ Sarah Lageman,² Leroy Thacker,³ Sally Russell,⁴ Marissa Mackiewicz,⁵ and Elvin Price,⁶ 1. *VCU School of Nursing, Ashland, Virginia, United States*, 2. *VCU Parkinson's & Movement Disorders Center, Richmond, Virginia, United States*, 3. *Virginia Commonwealth University Wright Center for Clinical and Translational Research, Richmond, Virginia, United States*, 4. *VCU School of Nursing, Richmond, Virginia, United States*, 5. *VCU Institute for Inclusion, Inquiry, and Innovation (iCubed): Health and Wellness in Aging Populations, Richmond, Virginia, United States*, 6. *Virginia Commonwealth University School of Pharmacy, Richmond, Virginia, United States*

Substantial gaps remain in the scientific literature regarding low-income minority older adult populations with

Alzheimer's disease and related dementias (ADRDs). Access to care and early cognitive screening are often barriers to advancing ADRD detection in low socioeconomic status (SES) minority older adults. Additionally, there is the need for demographically (age, education, sex, race, ethnicity, and income) corrected normative scores in cognitive measures. Our cross-sectional study evaluated the psychometrics of the Mini-Mental State Exam-2 (MMSE-2) and the NIH Toolbox Cognition Battery (NIHTB-CB). The sample consisted of $n=80$ community-based older adults without a diagnosis of dementia living in low-income high-rise housing units. Acceptability is assessed with a brief 6-item acceptability survey, multiple linear regression is used to get predicted cognitive scores adjusted for age, education, income, ethnicity, race, and sex, and t-test comparison of the adjusted scores found in this study to established norms. Results found a mean age of 73, 70% black, 48% with < 12th-grade education, 51% have a monthly income of < \$1,000, and 49% with undiagnosed cognitive impairment (CI) by both measures. When applying demographic adjustments in the NIHTB-CB 1) standard scores; 2) age-corrected scores, and 3) demographically correct scores all remained significant ($p > 0.0001$). Participants reported high (80-95%) acceptability for the community-based cognitive screening, 18% reported concerns with cultural appropriateness of the questions in the NIHTB-CB as compared to 5% with the MMSE-2. This research lays the foundation for a community-based cognitive screening and care coordination program for the low SES minority older adult population.

THE ROLE OF SOCIOECONOMIC INEQUALITIES IN TRANSITIONING TO NEUROCOGNITIVE DISORDERS IN ENGLISH POPULATION

Aswathikutty Gireesh,¹ Amanda Sacker,¹ Anne McMunn,² and Dorina Cadar,¹ 1. *University College London, London, England, United Kingdom*, 2. *University College London (UCL), London, England, United Kingdom*

The association between socioeconomic position (SEP) and dementia is well studied. However, scant attention has been given to the relationship with mild cognitive impairment (MCI), often considered a transient state between normal cognition and dementia. The purpose of this study was to determine the role of various SEP markers such as education and wealth on transitioning to MCI and dementia over a four-year period using data from the English Longitudinal Study of Ageing, a national representative sample of the English population aged 50+. We ascertained MCI and dementia over four years, using a validated algorithm based on physician diagnosis and lower cognitive performance (1 standard deviation below the mean) on multiple standardised tests adjusted for age and education. A Multistate Markov survival model was utilised to investigate whether different SEP markers increased the risk of specific transitions between normal cognitive performance and MCI or dementia, with the latter being considered an absorbing state. During the study period, a quarter of participants progressed to MCI from the normal state. Being in the lowest quintile of wealth was associated with a lower probability of transitioning back to a normal cognitive state from MCI, compared with those in the highest quintile. Greater wealth was weakly associated with a lower risk of transitioning from normal cognitive state

to MCI and from MCI to dementia. The overall results imply that socioeconomic advantage might be protective against rapid progression from mild to more severe neurocognitive disorders such as dementia in later life.

Session 9150 (Poster)

COVID-19 and Long-Term Supports and Services

BURNOUT, COMPASSION SATISFACTION, AND INTENT TO QUIT AMONG LONG-TERM CARE NURSING ASSISTANTS IN THE TIME OF COVID-19

Mallory Richert, *Xavier University, Cincinnati, Ohio, United States*

The COVID-19 pandemic has greatly exacerbated the stress and burden of those employed in long-term care (LTC) facilities due to staff shortages, increased risks on the job, and ever-changing COVID-19 protocol requirements. This study examines potential differences in pre-COVID-19 and current COVID-19 LTC facility employed nursing assistants on burnout, compassion satisfaction, job satisfaction, and intent to quit. The sample included 81 nursing assistants employed in LTC facilities across the United States, with data collected prior to ($n=42$) and during COVID-19 related shutdowns ($n=39$). Participants completed the Professional Quality of Life Scale 5 (ProQOL 5), a single-item self-report measure of job satisfaction, and a two-item self-report measure of intent to quit their current employment. Nursing assistants during COVID-19 reported a higher level of burnout and lower level of compassion satisfaction than nursing assistants Pre-COVID-19. However, there were no differences in job satisfaction or intent to quit. The results suggest there may be additional factors that influence an individual's decision to remain employed above and beyond the impacts of burnout and compassion satisfaction that may be unique to the caring professions. Future research might investigate factors that influence an individual's decision to remain employed as a nursing assistant during periods of increased stress and burnout. Additionally, the impact of COVID-19 related stress added to the already high levels of stress and burnout on nursing assistants calls for further attention and research devoted to psychological support of LTC staff during crisis and normal times.

CHALLENGES IN CARING FOR PEOPLE WITH DEMENTIA DURING COVID-19: FINDINGS FROM LONG-TERM CARE FACILITIES ACROSS JAPAN

Tomoko Ikeuchi,¹ Mizue Suzuki,² Kazunori Kikuchi,¹ Akiko Kan,¹ and Chiho Shimada,¹ *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan, 2. Hamamatsu University school of medicine, Hamamatsu, Shizuoka, Japan*

Long-term care facilities for older adults have been profoundly affected by the coronavirus disease 2019 (COVID-19) pandemic in Japan. This study investigated the challenges that care staff members faced by the height of the first wave (i.e., April 2020) and the height of the second wave (i.e., October 2020) of the pandemic at long-term care facilities in Japan. We mailed questionnaires in October 2020 to 5,895

care facilities throughout Japan. A total of 22.7% of the questionnaires were returned. Of those, 87.4% had at least one resident with dementia. Based on the results, 65.2% reported having restricted all visitors during the first wave. Although 42.8% reported continuing to restrict all visitors during the second wave, more than 54% allowed visitors while limiting the number of visitors or the time of each visit. Nearly 76% reported that restrictions on visitations may have exacerbated the behavioral and psychological symptoms of dementia (BPSD) among residents. In place of visitations, over 50% used video calls or phone calls to communicate with the family members, and 45.7% reported that the virtual visits were efficacious in alleviating the BPSD. However, more than 70% reported not having adequate Internet services and computer equipment at their facilities, and nearly 90% reported insufficient staffing. Our findings suggest that the pandemic may have pressed for a change of direction for dementia care with the introduction of virtual visitations and other initiatives. Nevertheless, facilities may face difficulties with implementing such changes due to inadequacies in the availability of resources.

DNR LINKED TO REDUCED DEPRESSIVE SYMPTOMS IN NURSING HOME RESIDENTS DURING COVID-19 ILLNESS

Wingyun Mak,¹ Orah Burack,¹ Joann Reinhardt,¹ Himali Weerahandi,² Benjamin Canter,³ and Kenneth Boockvar,¹ *1. The New Jewish Home, New York, New York, United States, 2. NYU Grossman School of Medicine, New York, New York, United States, 3. The New Jewish Home, The New Jewish Home, New York, United States*

Prior work shows that older adults who establish future care plans have a lower risk of depression. Residents in long-term care may benefit from establishing a do-not-resuscitate (DNR) order when cardiopulmonary resuscitation is unlikely to provide medical benefit. The current study examines whether having a DNR order in place prior to COVID-19 diagnosis was associated with fewer depressive symptoms during the illness course. Residents at a NYC skilled nursing facility with a positive COVID-19 PCR test between 3/1/2020 – 6/1/2020 were included ($N=338$). The Minimum Data Set (3.0) was used to examine residents' Patient Health Questionnaire-9 (PHQ-9) scores 1-30 days after diagnosis, functional status, cognition, age, and sex. A retrospective chart review was conducted to determine whether participants had an established DNR, DNI, and/or DNH order before developing COVID-19. Forty-eight percent, 46%, and 12% of participants had a DNR, DNI, or DNH order prior to COVID-19 illness, respectively. Average PHQ-9 score was 1.65 ($SD=2.37$). A hierarchical regression showed that after controlling for age ($\beta=-.13$, $p=.06$), sex ($\beta=.08$, $p=.28$), cognition ($\beta=.14$, $p=.04$), and functional status ($\beta=.23$, $p=.001$; $R^2=.10$, $p=.001$), having a DNR ($\beta=-.22$, $p=.006$) order in place prior to COVID illness was associated with lower endorsement of depressive symptoms during illness ($\Delta R^2=.04$, $p=.01$). Results suggest that establishing a DNR in long-term care residents when appropriate may potentially buffer depressive symptoms during illness in nursing home residents regardless of their age, sex, cognitive abilities, and functional status. Future examination of the underlying mechanism is warranted.

HOME CARE RESILIENCY DURING THE COVID-19 PANDEMIC: OLDER ADULT-HOME CARE AIDE DYADS' PERSPECTIVES

Naoko Muramatsu,¹ Lijuan Yin,¹ Maria Caceres,¹ and Jordan Skowronski,² 1. *University of Illinois Chicago, Chicago, Illinois, United States*, 2. *University of Illinois Chicago, University of Illinois Chicago, Illinois, United States*

Homecare has increased its value as an alternative to nursing homes and adapted to evolving COVID-19 challenges. However, little is known about how COVID-19 has impacted community-dwelling older adults who need assistance with daily activities, including dressing, cooking, and shopping. Guided by the stress process framework, this mixed-method study examined how older homecare recipients experienced the acute and chronic stress during the first eight months of the pandemic, focusing on the role of home care aides (HCAs) in the context of Medicaid-funded in-home services. Thirty-five dyads of care recipients and HCAs participated in a COVID telephone survey as part of a larger study. Care recipients were typically older minority (40% African American, 31% Latinx) women (77%). Their COVID-related anxiety level, assessed by a 6-item Spielberger State Anxiety Inventory (1 "not at all" to 4 "very much"), was 2.2 (SD=0.9). While COVID-19 drastically reduced contacts with family members and healthcare providers, HCAs continued to provide care in person. One care recipient said, "Fortunately, I still have my HCA come and that keeps me sane." HCAs showed resilience while facing their own family- and work-related stress: "I have followed the rules and just adapted. (COVID) did not affect the activities for my client." Some dyads, however, experienced care disruptions because of COVID infection or fear in one or both parties. COVID-19 has demonstrated homecare resilience at the person-, dyad-, and organization-levels, calling for equitable, sustainable home-based care for a growing number of older adults who desire to stay in the home.

PROVIDER COMMUNICATION AND LONELINESS IN SENIOR LIVING COMMUNITIES DURING THE COVID-19 PANDEMIC

Lindsay Wilkinson,¹ Julie Masters,² and Julie Blaskewicz Boron,¹ 1. *University of Nebraska Omaha, Omaha, Nebraska, United States*, 2. *University of Nebraska, Lincoln, Nebraska, United States*

Prior research has demonstrated the impact of the COVID-19 pandemic on feelings of loneliness, but relatively little is known about loneliness in the context of senior living communities (SLCs). Indeed, the pandemic has led SLCs to enact new safety precautions, including visitor restrictions, intended to reduce the spread of COVID-19, which may have serious consequences for the psychosocial well-being of residents. Drawing on a sample of 733 adults ages 54 to 100 living in one of nine SLCs in December 2020 (response rate = 60%), linear regression models were used to examine whether perceived communication between SLCs and residents during the COVID-19 pandemic influenced feelings of loneliness. Analyses also considered whether this association varied as a function of education. Our findings reveal that 53% of respondents were very lonely during the pandemic. However, older adults who perceived that their SLC had been

helpful to their understanding of the pandemic were significantly less lonely ($p < 0.01$), adjusting for sociodemographic and health characteristics. Moreover, we found that less educated older adults derived the greatest benefit from effective communication about the pandemic ($p < 0.05$). Those with less education reported feeling lonelier if they did not perceive that their SLC communicated in a way that helped them better understand the pandemic; there was no such association for those with higher education. The findings from this study provide support for the resource substitution hypothesis and demonstrate the importance of communication in alleviating feelings of loneliness during the COVID-19 pandemic.

SHIFTING INFORMATION-SEEKING BEHAVIORS OF RURAL OLDER AMERICANS DURING THE ERA OF THE COVID-19 PANDEMIC

Brady Lund, *Emporia State University, Wichita, Kansas, United States*

This session reports findings on how older rural adults in the Midwest United States adapted their information seeking behaviors in the face of the COVID-19 pandemic. A series of nearly three-dozen interviews conducted during late-summer 2020 capture the experiences of members of this population in their own words. Findings indicate that the experiences of the rural older American during this period were often unique to each individual and cannot be easily explained by a single social or demographic factor. Those participants with greater educational attainment were more likely to use a variety of digital technologies (smartphones, tablets, at-home personal computers) prior to the pandemic and thus experienced fewer challenges finding reliable information when the pandemic began. Those who were married felt less socially-isolated, but were often more reliant on others to find information for them. Women were more likely than people with other gender identities to use social media to connect and find information, which helped abate feelings of isolation but also made them feel more susceptible to misinformation and information overload. All participants expressed some level of fear or concern that motivated them to seek health information, while many expressed the same motivation in seeking political and economic information. These findings suggest that the information seeking behaviors of rural older adults were dramatically altered by the COVID-19 pandemic, with most becoming more reliant on digital technology to find information, and all being motivated by fear, concern, and/or curiosity to find information about the pandemic.

THE INTERPLAY OF COVID 19, REMOTE CONTACT, AND RACE AS RISK FACTORS FOR DEPRESSION

Youngjoon Bae,¹ Katherine Abbott,² and Mark Pachucki,¹ 1. *University of Massachusetts, Amherst, Amherst, Massachusetts, United States*, 2. *Miami University, Oxford, Ohio, United States*

There have been concerns about how social distance policies and lockdowns due to COVID-19 have affected loneliness and depression among older adults in ways that may magnify racial disparities in health. We conducted panel logistic regression analyses with random effects using national data spanning 2004 to 2016 and the COVID-19 module (Wave 2020, administered in June and September) from the

Health & Retirement Study (n=15,504). Individuals living in a nursing home, diagnosed with dementia or Alzheimer's disease, and 64 years of age or younger were excluded from analyses. Age, gender, Hispanic status, education, marital status, working status, wealth, BMI, physical activity, smoking, drinking, and difficulty in meal preparation, eating without help, and grocery shopping were included as control variables. Findings suggest that older adults did not appear to experience increased loneliness during the pandemic relative to prior waves. However, Wave 2020 was an independent risk factor for depression. Greater in-person contact (OR: 0.97, CI: 0.95-0.99, p-val: 0.001) and remote contact (OR: 0.99, CI: 0.97-0.996, p-val: 0.008) were each independently associated with slightly decreased depression. Older Black Americans tended to be more depressed than their White counterparts (OR: 1.50, CI: 1.20-1.86, p-val: <0.001). However, a null interaction between race and wave suggested that Black Americans did not experience more increased depression in 2020 relative to prior waves. Analyses suggest that the COVID-19 pandemic might change at-risk groups for depression and communication by remote technology – often considered an inferior but necessary stopgap measure. Implications for practice and policy will be discussed.

Session 9155 (Poster)

COVID-19 and Mental Health Among Older Adults

A COMPARISON OF MENTAL HEALTH IN A SAMPLE OF OLDER WOMEN BEFORE AND DURING THE COVID-19 PANDEMIC

Victoria Marshall,¹ Robina Sandhu,² Kathryn Kanzler,³ Sara Espinoza,¹ Pamela Keel,⁴ Andrea LaCroix,⁵ Nicolas Musi,³ and Lisa Kilpela,³ 1. *University of Texas Health Science Center San Antonio, San Antonio, Texas, United States*, 2. *University of Texas Health Science Center, San Antonio, Texas, United States*, 3. *UT Health San Antonio, San Antonio, Texas, United States*, 4. *Florida State University, Tallahassee, Florida, United States*, 5. *University of California at San Diego, San Diego, California, United States*

The COVID-19 pandemic has substantially impacted lives globally. Due to age-related risks, the older adult population has uniquely experienced negative changes caused by the pandemic. Research has also shown that the pandemic has disproportionately affected women. Therefore, it is important to understand how the mental health of older women has been impacted during this global crisis. This study aims to examine the differences in mental health indices in a sample of older women before versus during the COVID-19 pandemic. To date, participants include 201 women (aged 60-94) who completed an online survey of self-report measures assessing depression, anxiety, alcohol use, binge eating, positive affect, and emotional quality of life (QOL). We conducted one-way ANOVAs to compare each mental health construct in two samples of older women collected pre- and peri-pandemic. Results indicated that the peri-pandemic group reported significantly higher anxiety ($F = 5.25, p = .02$), with a trend for more role limitations due to emotional problems ($F = 2.79,$

$p = .09$), than the pre-pandemic group. No significant differences emerged for levels of depression, alcohol consumption, binge eating, positive affect, or emotional wellbeing between groups. These findings point to the psychological resilience of older adults in the face of extreme adverse events, including this global crisis. Older women, while impacted differently during the COVID-19 pandemic, reported minimal exacerbations of mental health problems compared to older women pre-pandemic. Efforts to identify moderators that may either attenuate or promote further psychological resilience among older adults is warranted.

BENEFIT-FINDING BUFFERS THE EFFECTS OF QUARANTINE ON OLDER ADULTS' MENTAL HEALTH DURING THE COVID-19 PANDEMIC

Sheung-Tak Cheng,¹ and Fan Zhang,² 1. *The Education University of Hong Kong, The Education University of Hong Kong, Hong Kong*, 2. *Jinan University, Jinan University, Guangdong, China (People's Republic)*

Objective: Older adults' health and well-being may suffer due to prolonged social isolation leading to loneliness and increased stress during the COVID-19 pandemic. The current study aimed to address the role of benefit-finding, defined as the capacity to derive meaning and positive aspects from stressful situations, in older adults' adaptation to the effects of quarantine. Methods: 421 participants aged 50 or above in China participated in an online survey to study the effects of quarantine on loneliness, stress, anxiety, depression and life satisfaction, and the moderating role of benefit-finding. Results: The results showed that quarantine was basically unrelated to any outcome. Further analysis showed, however, that the effect of quarantine varied by levels of benefit-finding. Only people with lower benefit-finding reported a higher level of loneliness, perceived stress, anxiety and depression, but no relationships were found at higher benefit-finding. Conclusions: The findings extended our understanding of the role of benefit-finding in buffering the negative impact of adversity on older people. By mitigating the effects of prolonged social isolation, benefit-finding served as a protective factor in older people's adaptation to the sequelae of this pandemic.

CHANGE IN STRESS AND POSITIVE EXPERIENCES AMONG OLDER OREGONIANS DURING THE COVID-19 PANDEMIC

Maria Kurth,¹ Hye Soo Lee,² Soyoun Choun,² Dylan Lee,² and Carolyn Aldwin,² 1. *Oregon State University, Wilsonville, Oregon, United States*, 2. *Oregon State University, Corvallis, Oregon, United States*

Several cross-sectional studies have examined stressors and positive events among older adults during COVID-19. We extend these studies by examining changes across time in perceptions of stress and positive experiences. Older adults in Oregon (Mage = 71.1, SD = 7.3, range = 51-95) completed weekly surveys from April 28 to June 23, responding to an adaptation of the Daily Stress Inventory (DISE; Almeida et al., 2002). DISE examines stressors and positive experiences across six domains (health, spouse/partner, other relationships, work/volunteer, finances, and retirement) on a 7-point scale (1 = not at all to 7 = extremely). At baseline, those who felt more stressed were younger, female, and reported more

chronic health conditions, while younger adults, especially males, reported more positive events. Positive and stress intensity scores were not correlated. Multilevel models found that for both positive, $B_{\text{linear}} = -2.54$, $SE = 0.52$, $p < .001$; $B_{\text{quadratic}} = 0.21$, $p < .05$, and stress, $B_{\text{linear}} = -0.79$, $p < .001$; $B_{\text{quadratic}} = 0.07$, $p < .01$, intensity showed decelerated decreases across time; residuals for both models were significant. Older adults had lower stress levels, while women and those with chronic health conditions had higher stress levels. Women also reported lower levels of positive events. In both models, neither age, gender, nor chronic health conditions predicted change. These results highlight the evolving experiences during COVID-19, as perceptions of stress and positive events decreased. Future studies should examine how the changing circumstances during COVID-19 affect adaptation, including perceived stress and positive events.

CORRELATES OF RESILIENCE OF OLDER PEOPLE IN TIMES OF CRISIS

Isabelle Albert,¹ Martine Hoffmann,² Elke Murdock,³ Josepha Nell,⁴ and Anna Kornadt,¹ 1. *University of Luxembourg, Esch-sur-Alzette, Luxembourg*, 2. *RBS, Itzig, Diekirch, Luxembourg*, 3. *University of Luxembourg, Esch-sur-Alzette, Diekirch, Luxembourg*, 4. *Luxembourg Ministry of Education, Children and Youth, Luxembourg, Diekirch, Luxembourg*

Since the beginning of the Covid-19 pandemic, efforts have been made to shield older adults from exposure to the virus due to an age-related higher risk for severe health outcomes. While a reduction of in-person contacts was necessary in particular during the first months of the pandemic, concerns about the immediate and longer-term secondary effects of these measures on subjective well-being were raised. In the present study, we focused on self-reported resilience of older people in a longitudinal design to examine risk and protective factors in dealing with the restrictions. Data from independently living people aged 60+ in Luxembourg were collected via a telephone/online survey after the first lockdown in June ($N = 611$) and September/October 2020 ($N = 523$), just before the second pandemic wave made restrictions necessary again. Overall, results showed an increase in life-satisfaction from T1 to T2, although life-satisfaction was still rated slightly lower than before the crisis. Also, about a fifth of participants indicated at T2 difficulties to recover from the crisis. Participants who reported higher resilience to deal with the Covid-19 crisis at T2 showed higher self-efficacy, agreed more strongly with measures taken by the country and felt better informed about the virus. In contrast, participants who reported more difficulties in dealing with the pandemic, indicated reduced social contacts to family and friends at T2, and also felt lonelier. Results will be discussed applying a life-span developmental and systemic perspective on risk and protective factors in dealing with the secondary impacts of the pandemic.

COVID-19 AND ITS IMPACT ON OLDER ADULTS' ROUTINE AND URGENT HEALTH CARE VISITS

Lindsay Wilkinson,¹ Julie Masters,² and Julie Blaskewicz Boron,¹ 1. *University of Nebraska Omaha, Omaha, Nebraska, United States*, 2. *University of Nebraska, Lincoln, Nebraska, United States*

Older adults have not only been disproportionately affected by the COVID-19 pandemic, but relatedly, are also more vulnerable to other health problems. Moreover, previous research on epidemics shows that health care services are often disrupted during health crises—leading to less access to and lower utilization of health services unrelated to the health crisis. The primary aim of this research is to examine the impact of the COVID-19 pandemic on both routine and urgent health care visits. Using data collected in December 2020 on adults ages 54 to 100 living in one of nine senior living communities (SLCs) in the state of Nebraska ($n = 723$), logistic regression models were used to investigate correlates of missed health care visits, adjusting for sociodemographic and health characteristics. The results show that 58% of older adults in SLCs skipped or postponed a routine health care visit due to the pandemic, whereas 8% of older adults missed an urgent health care visit. The results further reveal that older adults with better perceived health ($p < 0.05$), higher life satisfaction ($p < 0.01$), and higher resilience ($p < 0.05$) all had lower odds of missing a routine health care visit due to the pandemic. In contrast, those who missed an urgent health care visit were more likely to have higher perceived financial strain ($p < 0.05$). The findings from this study demonstrate the consequences of the COVID-19 pandemic on older adults' health care utilization, which may have serious implications for their long-term health.

EMERGENCY PREPAREDNESS IN 2010 AND CONCERNS ABOUT COVID-19: EVIDENCE FROM THE HEALTH AND RETIREMENT STUDY

Timothy Killian,¹ Betsy Garrison,² and Charleen McNeill,³ 1. *University of Arkansas, Fayetteville, Arkansas, United States*, 2. *University of Arkansas, University of Arkansas, Arkansas, United States*, 3. *East Carolina University, East Carolina University, North Carolina, United States*

Emergency preparations are particularly important for older persons as age-related vulnerabilities increase risk of morbidity and mortality associated with disasters. The novel COVID-19 virus combined with the ongoing efforts of the Health and Retirement Study (HRS) has provided researchers with the opportunity to examine how emergency preparedness was related to responses to the COVID-19 disaster approximately 10 years later. The data for this study were generated from participants in the HRS. This study only examined data from participants in both the disaster preparedness sub-sample of 2010 and COVID-19 sub-sample in 2020 resulting in data from 249 participants. In 2020, participants were asked how concerned they were about COVID-19 and whether or not they had been tested for the virus. This study found that disaster preparations in 2010 predicted lower levels of concern about COVID-19 in 2020. The differences in the means for all items, however, was not large enough to reach statistical significance with one exception, participating in an educational program about disaster preparedness (Wilcoxon- $Z = -1.88$, $p < .05$). Disaster preparations were associated with an increased likelihood of getting tested for COVID-19 for four of the six items. Statistical significance, however, was only achieved for a single item. Participants who had supplies for a three-day emergency in 2010 had higher rates of getting tested in 2020 (24.84%) as compared to those who did not have supplies

for a three-day emergency (14.13%; $\chi^2 = 4.03$, $p < .05$). If accepted for presentation, implications for an array of audiences will be developed.

EXPLORING THE “NEW NORMAL”: OLDER ADULTS’ COPING STRATEGIES DURING COVID-19 PANDEMIC

Novia Nurain,¹ Lesa Huber,² Clara Caldeira,³ and Kay Connelly,³ 1. *Indiana University, Indiana University, Indiana, United States*, 2. *School of Public Health, Indiana Univ, Bloomington, Indiana, United States*, 3. *Indiana University, Bloomington, Indiana, United States*

COVID-19 stay-at-home orders resulted in social isolation and psychosocial challenges for older adults around the world. To understand their lived experiences during the pandemic, we conducted a qualitative study using semi-structured interviews with 15 older adults living in community settings. Qualitative thematic analysis of the collected data identified themes and patterns of the “new normal” for these participants: ways of living, communication with family and friends, sense of autonomy, psychological responses, coping strategies, and perceived social support. This presentation focuses on participants’ coping strategies. Participants used common coping strategies, customized to the unique challenges of stay-at-home orders. We categorized coping strategies as problem-focused, meaning-focused, and emotion-focused. Participants’ problem-focused strategies aimed to reduce the risk of infection. Meaning-focused strategies included purposeful errands such as going to grocery stores. Emotion-focused strategies emphasized connecting with support networks (e.g., via Zoom) and efforts to maintain psychosocial and emotional well-being (e.g., seeking professional counseling). They also employed self-enhancing comparisons to increase self-concept and self-esteem. At the beginning of the pandemic, some temporarily used distraction/avoidance strategies such as eating comfort food and avoiding news about COVID-19 to maintain a positive emotional state. Our findings imply the applicability of frameworks such as life course perspective and selective optimization with compensation to highlight the successful adaptive strategies developed by older adults through experience. We argue against the ageist view of older adults as vulnerable. Rather, this study suggests that older adults can flexibly employ resilient coping strategies crafted over a lifetime of experiences in response to crises.

LINKING COPING BEHAVIOR AND MENTAL WELL-BEING IN OLDER ADULTS DURING THE COVID-19 PANDEMIC

Dugan O’Connor, and Jennifer Smith, *Mather, Evanston, Illinois, United States*

In addition to being a significant source of stress, the COVID-19 pandemic required older adults to drastically alter their behaviors and routines. People cope with stress in various ways; however, the pandemic was a unique situation that warranted investigation of this topic. This study aimed to identify the ways older adults coped with the COVID-19 pandemic, and the relationship between specific coping behaviors and perceived stress and mental health. Two hundred thirty-one older adults, ages 53 to 90, completed an online survey about coping behaviors used to manage stress during the pandemic, as well as measures of loneliness, depression,

perceived stress, and the negative impact of the COVID-19 pandemic on their lives. “Talking with friends and family” (83%) and “increased television watching or other screen-time” (68%) were the most common coping behaviors. A series of one-way analyses of covariance (ANCOVA), with race, gender, age, education, and income included as covariates, revealed “eating more often” and “drinking alcohol” were associated with greater loneliness, depression, and stress. “Increased screen time” was also associated with greater depression and stress. “Engaging in more family activities,” was associated with a less negative impact of the pandemic, and “talking with friends and family” was associated with less loneliness. These findings suggest older adults who coped with stress of the COVID-19 pandemic through more eating, drinking, and the second most common behavior—watching TV—were more likely to report poorer well-being, and may benefit from programs to boost virtual social engagement.

MENTAL HEALTH CONSEQUENCES OF THE COVID-19 PANDEMIC AMONG OLDER ADULTS WITH CHRONIC CONDITIONS

Courtney Polenick,¹ Diarratou Kaba,² Summer Meyers,² Annie Zhou,² Nikita Daniel,² Shreya Salwi,² and Vanessa Lee,² 1. *University of Michigan, Ann Arbor, Michigan, United States*, 2. *University of Michigan, University of Michigan, Michigan, United States*

The COVID-19 pandemic may have a negative impact on mental health, especially among older adults with chronic conditions who are more vulnerable to severe illness. This cross-sectional qualitative study evaluated how the pandemic has impacted the ways that adults aged 50 and older with chronic conditions managed their mental health. Participants included a total of 492 adults ($M = 64.95$ years, $SD = 8.91$, range = 50 – 94) from Michigan (82.1%) and 33 other U.S. states who reported a diagnosis of at least one chronic condition and completed an anonymous online survey between May 14 and July 9, 2020. Participants provided open-ended responses to a question about the pandemic’s impact on how they were taking care of their mental health. The data were coded to ascertain relevant concepts and were reduced to develop major themes. We determined four main themes. The pandemic impacted how participants took care of their mental health through: (1) pandemic-related barriers to social interaction; (2) pandemic-related routine changes; (3) pandemic-related stress; and (4) pandemic-related changes to mental health care. Taken as a whole, this study indicates that older adults with chronic conditions encountered a variety of challenges to managing their mental health in the early months of the COVID-19 pandemic, but also demonstrated considerable resilience. These findings identify potential risk and protective factors to target as part of personalized interventions to preserve their well-being during this pandemic and in future public health crises.

OLDER ADULTS AND THE IMPACT OF COVID-19: LESSONS LEARNED FROM A TWO-STATE STUDY

Amanda Sokan,¹ and Tracy Davis,² 1. *The University of Arizona, University of Arizona, Arizona, United States*, 2. *Rutgers University, New Brunswick, New Jersey, United States*

The COVID-19 pandemic has led to increased strains on the rapidly increasing aging population's mental, emotional, and physiological health. COVID-19, which belongs to a family of respiratory viruses, was first detected in China before spreading to other parts of the globe. Due to underlying health conditions and weakened immune systems, the aging population is at greater risk for contracting COVID-19. To better prepare for a future pandemic, it is necessary to explore the psychosocial impacts of limited human interactions to make the aging population feel safer while mitigating harm to their mental and emotional health. The purpose of this study is to highlight the experiences of the aging population with COVID-19, including psychosocial, behavioral responses to the pandemic, and older adults' overall well-being. We surveyed a total of 203 adults 55 and older regarding their experiences with the pandemic. Survey components included the COVID-19 Household Environment Scale (Behar-Zusman, Chavez, & Gattamorta, ND), selected items from the COVID-19 Impact Study and open-ended questions, the Generalized Anxiety Disorder Assessment (Williams et al., 2006), and the UCLA Loneliness Scale (Russell, Peplau, & Ferguson, 1978). Preliminary analyses indicate that most participants had not experienced any COVID-19 symptoms, nor did they know anyone who had passed away from the virus. However, participants did report loneliness and less family cohesion because of the pandemic. Findings from this study will be used to help older adults cope with the impact of the current pandemic and future pandemics.

OLDER AGE AND OTHER PROTECTIVE FACTORS OF MENTAL HEALTH DURING THE COVID-19 PANDEMIC IN THE US

Kelly Smith,¹ Amanda Chappell,² Rachael Spalding,¹ Jenna Wilson,¹ Ilana Haliwa,¹ and JoNell Strough,¹ 1. *WVU, Morgantown, West Virginia, United States*, 2. *West Virginia University, Morgantown, West Virginia, United States*

Research conducted early in the COVID-19 pandemic (i.e., March 2020) suggested that older adults were less likely to experience negative pandemic-related mental health than younger people. We investigated whether this age-related advantage persisted during the July 2020 spike in COVID-19 cases and investigated links between coping strategies and mental health. We used data from the Understanding America Study (UAS) to conduct a secondary data analysis of participants (N = 5,753) aged 18-110 years (M=46.20, SD=12.88) who completed online self-report surveys twice—once immediately prior to the July spike in cases, and again during the spike. Surveys assessed engagement in protective behaviors (e.g., wearing a mask, washing hands), coping strategies (e.g., calling family/friends, getting extra exercise, meditating), and anxiety and depressive symptoms (using the Patient Health Questionnaire PHQ-4). Multiple regression analyses were used to identify predictors of anxiety and depression during the spike, controlling for previous anxiety and depression, race, ethnicity, income, education, and marital status. Older age and engaging in protective behaviors were associated with less anxiety, whereas coping by calling family/friends was associated with more symptoms, $R^2 = .71$, $F(16, 5736) = 885.90$, $p < .001$. Coping by calling and getting extra exercise were associated with fewer depressive symptoms, whereas coping by using social media was associated with

more symptoms, $R^2 = .72$, $F(16, 5736) = 906.65$, $p < .001$. These findings highlight age as a protective factor for anxiety but not for depression and underscore the importance of social support as a protective factor for mental health.

ONLINE LEISURE ACTIVITIES FOR SUSTAINED MENTAL HEALTH WELL-BEING IN OLDER ADULTS WITH COVID-19 MITIGATION

Solymar Rivera-Torres,¹ Elias Mpfu,² M. Jean Keller,² and Stan Ingman,² 1. *University of North Texas, Denton, Krum, Texas, United States*, 2. *University of North Texas, University of North Texas, Denton, Texas, United States*

Older adults (OA) experience psychosocial distress from the COVID-19 pandemic mitigations. While their participation in leisure and recreation activities (LRA) would be ameliorating, we do not know how LRA OA engages for their mental health (MH) well-being with COVID-19 mitigation. This scoping review aimed to trend the evidence on the types of LRA OA engage for their MH well-being across the young-old continuum (60-69 years) through to older-old (80 years and above) in the COVID-19 pandemic. We searched the following electronic databases (PubMed, EMBASE, CINAHL, Cochrane, JBI-ES, and Epistemonikos) for LRA studies by OA with COVID-19 mitigation. To be included, we considered empirical articles published in English on LRA of OA 55+ years-old. Another criterion required articles describing those activities' qualities and the impact of LRA on MH and well-being during the COVID-19 pandemic. We resulted in seven empirical studies, two of which implemented in the USA and one from the USA and Canada, Spain, Israel, and Japan. Findings following narrative synthesis revealed trending evidence on OA to engage in online LRA for social, cognitive /intellectual, and emotional health. Leisure-time physical activity reduced negative MH symptoms as anxiety and depression in OA under COVID-19 threat. In conclusion, the present review's trending evidence suggests that OA engagement in social, physical, mental, and cognitive LRA enhanced their MH and overall well-being. Activities delivered by way of the Internet and television provided a cluster of beneficial opportunities for the OA mental health needs under the COVID-19 pandemic.

PERCEIVED IMPACT OF COVID-19 ON OLDER ADULTS' MENTAL HEALTH AND BARRIERS TO MENTAL HEALTH CARE

Grace Caskie,¹ Madison Tschauner,¹ and Eve Root,² 1. *Lehigh University, Bethlehem, Pennsylvania, United States*, 2. *Lehigh University, Philadelphia, Pennsylvania, United States*

COVID-19 disproportionately impacted older adults in terms of fatalities, but also increased stress, isolation, and loneliness (Chen, 2020). We examined older adults' anxiety, depression, and barriers to mental healthcare during the COVID-19 pandemic and their perceptions of these variables prior to the pandemic. Further, we explored whether any perceived changes differed based on geographical location (rural, suburban, urban). Data were collected online between mid-June and mid-July of 2020 from 244 individuals aged 65-82 years (M=68.3, SD=3.5). The sample was primarily White (91%) and female (60%); most (n=119) lived in suburban settings, with 63 in urban and 60 in rural settings. Repeated-measures ANOVAs at

alpha=.01 showed that depressive symptoms, measured by the CESD-10 ($p<.001$), and anxiety symptoms, measured by the GAD-7 ($p<.001$), increased during the pandemic as did mental healthcare barriers related to transportation ($p=.004$) and beliefs that depression is a normal part of aging ($p<.001$). Only transportation concerns differed based on where older adults lived; those in rural ($p<.001$) and urban ($p=.004$) settings reported greater transportation barriers than those in suburban settings. No differences over time were found for barriers related to help-seeking ($p=.403$), stigma ($p=.156$), knowledge/fear ($p=.180$), finding a therapist ($p=.030$), ageism ($p=.302$), psychotherapist qualifications ($p=.265$), physician referrals ($p=.207$), or finances ($p=.818$). These findings highlight the impact of COVID-19 on older adults' perceptions of changes in their psychological well-being as well as their experience navigating mental health services.

PERSONALITY AND CHANGE IN PERCEIVED CONTROL ACROSS THE FIRST FOUR MONTHS OF THE CORONAVIRUS PANDEMIC

Amanda Sesker,¹ Ji Hyun Lee,² Martina Luchetti,¹ Damaris Aschwenden,³ Yannick Stephan,⁴ Antonio Terracciano,⁵ and Angelina Sutin,¹ 1. *Florida State University College of Medicine, Tallahassee, Florida, United States*, 2. *University of Michigan, Ann Arbor, Michigan, United States*, 3. *Florida State University, Tallahassee, Florida, United States*, 4. *University of Montpellier, Montpellier, Languedoc-Roussillon, France*, 5. *FLORIDA STATE UNIVERSITY, Florida State University, Florida, United States*

Objective. This study examined change in perceived control (PC) across the first four months of the global coronavirus pandemic and whether change varied significantly by age and personality traits during the first four months of the pandemic. **Methods.** Personality was assessed prior to the pandemic in a large national sample of 2,455 American adults (18-100 years) from a preregistered online survey (<https://osf.io/q8cpd>), first conducted between January 31, 2020 and February 10, 2020. Three additional follow-up waves were conducted: mid-March 2020 (following the World Health Organization declaration of the coronavirus a pandemic), late April 2020 (toward the end of the White House's 30 Days to Slow the Spread guidance), and late July 2020 (when patient deaths in the U.S. reached 132,918). PC was assessed in Waves 2-4. **Results.** There were age differences in the trajectory of PC such that PC increase for middle-aged and older adults, whereas younger adults had lower PC and did not increase over the follow-ups. All personality traits but Openness were associated with PC at the first assessment. Conscientiousness, Extraversion, and Agreeableness positively predicted PC change over time. The association between Conscientiousness and Extraversion and increased PC over time was stronger at older ages. **Conclusion.** Pre-pandemic personality predicted PC and PC change during the first four months of the pandemic, with middle-aged and older adults showing better adaption than younger adults. This study provides new evidence for PC change and associations between personality and PC during the COVID-19 pandemic.

PHYSICAL ACTIVITY, SOCIAL SUPPORT, AND MOOD IN OLDER ADULTS DURING THE COVID-19 PANDEMIC

Morgan Inman,¹ Clare Murphy,¹ and Jessica Strong,²

1. *University of Prince Edward Island, University of Prince Edward Island, Prince Edward Island, Canada,*

2. *University of Prince Edward Island, Charlottetown, Prince Edward Island, Canada*

Research shows that increased physical activity is associated with improved mood and reduced symptoms of depression in older adults. Prior research has also found that loneliness and social isolation have a significant impact on the mental and physical well-being of older adults, with higher amounts of social connectedness and social activity associated with more frequent positive mood states. Overall social isolation is increased due to the COVID-19 pandemic and this could have a large impact on the physical and mental health of older adults. A group of 36 community dwelling older adults (Mean age = 70.5) completed questionnaires measuring physical activity, social activity, and social support, during the COVID-19 pandemic. Analyses found that perceived social support and average social network size significantly predicted positive mood states ($F(2,33)=3.32$, $p<0.05$) accounting for 16.7% of the variance, with a large effect. After adding average number of hours of sedentary activity the model was not significant. Perceived social support was more predictive of positive mood ($\beta=0.32$) compared to network size ($\beta=0.17$). There was a trend for the same three variables to predict negative mood ($F(3,32)=2.76$, $p=0.06$) accounting for 22% of the variance. Sedentary behaviour was the most predictive ($t=2.68$, $p<0.05$, $\beta=0.49$). This suggests that perceived social support is most predictive of positive mood, and sedentary behaviour is predictive of negative mood during the COVID-19 pandemic.

PROTECTIVE AND RISK FACTORS OF DEPRESSION AMONG OLDER ADULTS DURING THE COVID-19 PANDEMIC

Yeonjung Lee,¹ and Tyran Terada,² 1. *University of Hawai'i at Mānoa, Honolulu, Hawaii, United States,* 2. *University of Hawai'i, Honolulu, Hawaii, United States*

The coronavirus disease 2019 (COVID-19) pandemic adversely impacted the mental health of older adults. This study aims to explore the associations between protective/risk factors of depression during the pandemic and to examine the differences in these associations by marital status. Data from the Health and Retirement Study 2020 COVID-19 module, released in February, 2021, were used. The level of resilience during the pandemic was selected as a protective factor. The level of COVID-19 pandemic concern was selected as a risk factor. Among older adults aged 51 years and older, the weighted regression model found that higher levels of COVID-19 concern were associated with higher levels of depressive symptoms ($p<0.05$), whereas higher levels of resilience were associated with lower levels of depressive symptoms ($p<0.05$). Marital status moderated the association between COVID-19 concern and depressive symptoms. Never-married people were at higher risk of depressive symptoms than married people when COVID-19 concerns increased. It is important to enhance support for never-married

people during the pandemic to protect their psychological well-being.

SOCIAL ISOLATION, DEPRESSIVE SYMPTOMS AND PERCEIVED NEIGHBORHOOD ENVIRONMENT OF OLDER ADULTS DURING COVID-19

Ke Li,¹ and Fengyan Tang,² 1. *University of Pittsburgh, Sandy Springs, Georgia, United States,* 2. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Social isolation has been recognized as a social problem with negative effects on psychological well-being. Older adults are disproportionately affected by social isolation during the COVID-19 pandemic. Using data from the 2020 Health and Retirement Study COVID-19 Project, this study examined the relationship between social isolation and depressive symptoms among two groups of respondents differentiated by whether themselves or their social relationships were diagnosed with COVID-19. This study also explored the moderating role of perceived neighborhood environment. Depressive symptoms were measured using the eight-item CES-D. The index of social isolation was generated using five indicators, including living alone, no social participation, and less than monthly contact with children, family members, and friends. The moderator assessed two aspects of the neighborhood environment, including physical disorder and social cohesion. The results of bivariate analyses showed that respondents who were affected by COVID-19 were younger, more likely to be female, Hispanic, and Non-Hispanic Black, and with lower levels of social isolation. The results of multiple regression analyses indicated that social isolation was associated with more depressive symptoms, but this relationship was found to be only significant among respondents who were affected by COVID-19. Perceived neighborhood environment significantly moderated the relationship, as the effect of social isolation on depressive symptoms was stronger for respondents with more neighborhood physical disorders and less social cohesion. This study has implications for practice and policy, in that it underscored the importance of enacting strategies to improve the neighborhood environment, particularly for socially isolated older adults during the COVID-19.

THE EFFECT OF VACCINES ON OLDER AFRICAN AMERICANS EMOTIONAL EXPERIENCES DURING THE COVID-19 PANDEMIC

Sophie Hanna,¹ Dwana Bass,² Sarah Shair,³ Loraine DiCerbo,¹ Bruno Giordani,⁴ and Voyko Kavcic,¹ 1. *Wayne State University, Detroit, Michigan, United States,* 2. *Institute of Gerontology - Wayne State University, Sterling Heights, Michigan, United States,* 3. *University of Michigan, University of Michigan, Michigan, United States,* 4. *Neuropsychology/Michigan Alzheimer's Disease Research Center, University of Michigan, Ann Arbor, Michigan, United States*

The COVID-19 pandemic is an unprecedented health emergency that has forced a change in the daily life of all individuals across the nation for over a year. As vaccinations have begun in Detroit, we examined their effect on older African Americans' emotional experiences and intent to get vaccinated during the pandemic to help understand

how persons make decisions to accept vaccinations. For this study, 194 community-dwelling older African Americans (mean age = 75, age range = 64-94) were recruited from the Wayne State Institute of Gerontology Healthier Black Elders Center and general Detroit area. A telephone survey was administered to assess pandemic experience including demographics, emotional responses (e.g., gratitude, happiness, anger, fear), everyday stressors (e.g., economic problems, reduced privacy), and vaccination attitude (e.g., concern over safety, intent to vaccinate). Of the 194 participants, 149 completed the survey before the first vaccination occurred in the United States on December 15, 2020, and 45 completed the survey after. Participants had not yet been vaccinated, but 67% said they would as soon as available. Participants in the post-vaccination group, as compared to pre-vaccination group, showed increases in stress-related locus of control ($p=.03$) and reported being more likely to get vaccinated ($p=.02$). They showed decreased worry about availability of health and safety supplies ($p=.01$), reduced perceived stress ($p=.02$), and a decrease in fears of COVID-19 ($p=.05$) and vaccination safety ($p<.001$). The current study highlights the effect of vaccinations on the attitudes and emotions experienced by an older minority population living in an urban area.

THE IMPACT OF COVID-19 CONCERNS ON THE MENTAL HEALTH OF OLDER ADULTS: A RAPID REVIEW

Sophia Perez, Alexandria Nuccio, and Ashley Stripling, *Nova Southeastern University, Fort Lauderdale, Florida, United States*

The Coronavirus (COVID-19) Pandemic continues to drastically impact older adults. Despite COVID-19 being linked to increased social isolation and loneliness, more research is needed on the psychological effects associated with older adults' concerns of the pandemic. The current review explores associations between the COVID-19 Pandemic and older adults' mental health to increase awareness and understanding. For this rapid review, empirical peer-reviewed source documents were identified through a computerized search using APA PsycInfo and Google Scholar bibliographical databases covering the years 2019 to 2021. The following keywords and combinations were used: "older adults," "COVID-19," and "mental health effects." Relevant exclusion criteria were applied, and all related English-language journal articles were read. 47 articles met inclusion criteria. Eight associated COVID-19 stress with loneliness, anxiety, depression, sleep disturbances, and poor psychological well-being, with three additional articles reporting elevations in women. Three articles revealed mixed findings regarding the impact of age on psychological variables. 13 articles evaluated changes among those with psychological/psychiatric diagnoses, and six explored physical activity and depression. Of the remaining articles, two concentrated on nutrition; seven examined routines, behaviors, and societal or risk perceptions; two evaluated coping mechanisms; and three examined emotional distress changes. Understanding COVID-19's psychological impact on older adults will take time. This rapid review revealed mixed findings regarding COVID-19 related concerns on older adults' psychological well-being, with multiple demographic variables uniquely

impacting these outcomes. It is imperative that future research explore older adults' risks and develop interventions related to the psychological impact of COVID-19.

THE MEDIATING ROLE OF RUMINATION AND PERSONAL GROWTH ON PANDEMIC DEPRESSION: A LONGITUDINAL STUDY

Teresa Paniagua,¹ Virginia Fernández-Fernández,² and M^aÁngeles Molina Martínez,³ *1. Universidad Europea de Madrid, Majadahonda, Madrid, Spain, 2. Universidad Nacional de Educación a Distancia, Madrid, Madrid, Spain, 3. Universidad Francisco de Vitoria, Madrid, Madrid, Spain*

Introduction: The experience of recent months, caused by COVID-19 pandemic including strict home confinement, has required older people to implement coping strategies to combat the harmful effects of depression and associated loneliness. Method: longitudinal study, including functionally and cognitively independent people over 65, three temporal evaluation measures: WAVE1 (6 months pre-COVID-19, N=305; M=73.63; 58.9% women), WAVE2 (during home confinement; N=151; M=73.14; 59.6% women) and WAVE3 (8 months post-WAVE2; N = 85; M=72.62; 64.70% women). Bivariate correlations and a multiple hierarchical regression model are performed to explain the variance of depression in WAVE3 from rumination and growth on general life events (in WAVE1) and rumination and personal growth associated with COVID-19, both in WAVE2 and WAVE3. Results: statistically significant correlations are obtained between all the variables. The regression model explains 65.7% of the variance of depression (all steps significant). Both rumination ($B=0.45$; $p=0.00$) and growth ($B=-0.40$; $p=0.00$) on general life events (WAVE1) explain 54.5% of the depression in WAVE3. Rumination on COVID ($B=.310$; $p<0.01$) in WAVE2 and the growth over COVID ($B=-0.24$; $p<0.01$) in WAVE3, allow a significant explanation of 6.8 and 4.4% of the proposed model, respectively. Conclusions: it seems clear the impact that emotional regulation strategies have on life events over time. In addition, rumination is an emotional process of maladaptive coping also in the face of the pandemic. However, the growth capacity of the person is a useful tool to combat the damaging effects of negative life events. In the elderly, it seems necessary to influence and bet on positive coping strategies.

THE RELATIONSHIP BETWEEN COVID-19 ANXIETY AND WELL-BEING OUTCOMES IN OLDER VETERANS

Sara Kintzle, and Carl Castro, *University of Southern California, Los Angeles, California, United States*

Understanding the impacts of the COVID-19 pandemic on the well-being of vulnerable populations is essential in planning for care post pandemic and preparing for future pandemics. One such population often overlooked during the COVID-19 pandemic is older veterans, whose military service often results in physical and psychological effects that creates vulnerability to the impacts of COVID-19 beyond their age risks. The purpose of this research was to examine the relationship between COVID-19 anxiety and well-being in older veterans. Survey data was collected from the end of June 2020 through August 2020 and examined the well-being of veterans during the COVID-19 pandemic. This research looked at the 122 veterans in the sample who

were aged 65 and older. Age ranged from 65 to 94 years ($M=73$, $SD = 5.0$). The sample was predominately Male (90%), White (83%), educated (65%) and married (69%). Moderate to high COVID-19 anxiety was reported in 38 percent of the sample. Older veterans who reported moderate to high COVID-19 anxiety were 5 times more likely to report loneliness, 11 times more likely to meet the diagnostic cut off for anxiety, 3 times for depression, 2 times for PTSD, and 3 times for moderate to severe insomnia. Results revealed a clear association between COVID-19 anxiety and the well-being of older veterans. Findings have implications for ensuring well-being outcomes are restored in older veterans as cause for pandemic anxiety is reduced. Results also demonstrate older veterans should be recognized as a vulnerable population in preparation for care future pandemics.

Session 9160 (Poster)

Covid-19 and Older Adults

CHALLENGES WITH CONDUCTING AN INVESTIGATIONAL DRUG STUDY IN OLDER ADULTS IN NURSING HOMES DURING A PANDEMIC

H Edward Davidson,¹ Lisa Han,¹ Melissa LaMantia,¹ Michelle Trout,² Joan Mannick,³ and Stefan Gravenstein,⁴
 1. *Insight Therapeutics, LLC, Norfolk, Virginia, United States*, 2. *Insight Therapeutics, LLC, Insight Therapeutics, LLC, Virginia, United States*, 3. *Life Biosciences, Boston, Massachusetts, United States*, 4. *Brown University, Providence, Rhode Island, United States*

In the early months of the pandemic, SARS-CoV-2 infected nursing home residents in explosive and deadly outbreaks. Nursing home residents disproportionately accounted for over 40% of COVID-19 mortality nationally. This national emergency drove scientific and public health experts to develop and implement administrative, clinical, and research programs to limit the pandemic's impact, especially for high-risk individuals, such as those hospitalized or living in nursing homes. Nursing home policies, prompted by the Centers for Medicare & Medicaid Services (CMS) and the Centers for Disease Control and Prevention (CDC) guidance, severely restricted access beginning in March 2020 in an effort to limit disease exposure. In July 2020 we began the process to conduct an investigational SARS-CoV-2 post exposure prophylaxis study of nursing home residents, incorporating FDA guidance developed for conducting investigational drug trials in the context of COVID-19. Our research teams adapted our nursing home engagement, resident consenting and research data collection strategies accordingly. We remotely screened residents living in any of 28 nursing homes for eligibility to participate, ultimately consenting and randomizing individuals in 11 facilities. Of the 2,683 nursing home residents 65 years or older we screened, 48 (1.8%) agreed to consent individually or through proxy, most often a legally authorized representative. We will describe our research methods, with emphasis on how we addressed challenges presented due to performing all research tasks remotely and identify strategies that can qualitatively improve the remote nursing home research experience.

CHARACTERIZING PATIENTS AND THEMES OF SARS-COV-2 VACCINE HESITANCY IN A NEW YORK CITY HIGH-RISK OLDER POPULATION

Stephanie Chow,¹ Yuji Yamada,² Lizette Munoz,³ Susana Lavayen,⁴ Jodi Payne,² Kavya Sreevalsan,² and Shamsi Fani,²
 1. *Icahn School of Medicine at Mount Sinai, New York, New York, United States*, 2. *Icahn School of Medicine at Mount Sinai, Icahn School of Medicine at Mount Sinai, New York, United States*, 3. *Mount Sinai Health System, New York, New York, United States*, 4. *Mount Sinai Hospital, Mount Sinai Hospital, New York, United States*

Background: Vaccines to prevent SARS-CoV-2 infection are deemed one of the most promising measures in controlling the devastating pandemic, yet there is significant vaccine hesitancy in some communities. Historic systemic health, discrimination, and structural inequities in specific racial and ethnic communities contribute to vaccine hesitancy with disproportionately negative impact. It is therefore critical to better understand vaccine hesitancy in this high-risk older population. The ALIGN (Acute Life Interventions, Goals, and Needs) program co-manages a panel of older patients with complex medical and psychosocial needs in an urban academic medical center. Methods: ALIGN enrolled or graduated Patients or designated healthcare proxies were contacted by telephone to discuss SARS-CoV-2 vaccine willingness and hesitancy using a standardized web-based survey. Qualitative data was categorized into themes and subgroups. Demographic data was collected by chart review. Results: Complete results are forthcoming and will include patient reported race and ethnicity baseline, vaccine hesitancy perceptions, with common overarching themes, and clinical team member debriefing. Iterative quality improvement actions taken based on elicited patient themes will also be included and assessed in telephone follow-up for changes in vaccine hesitancy. Conclusions: We are conducting a qualitative and quality improvement study characterizing vaccine perceptions and hesitancy in a high-risk older group with focus on racial and ethnic disparities in this population. This preliminary data informs healthcare providers of potential health literacy, cultural and language, and other potential barriers in order to help further understand how to optimize SARS-CoV-2 vaccine acceptance and delivery in a patient population with elevated risk.

COVID-19 IMPACTS ON MENTAL HEALTH CARE IN VETERANS HEALTH ADMINISTRATION COMMUNITY LIVING CENTERS

Jenefer Jedele,¹ Cameron Griffin,² Kim Curyto,³ and Michele Karel,⁴
 1. *Veterans Health Administration, Ann Arbor, Michigan, United States*, 2. *VA, Ann Arbor, Michigan, United States*, 3. *VA Western New York Healthcare System, Batavia, New York, United States*, 4. *Veterans Health Administration, Washington, District of Columbia, United States*

COVID-19 forced VHA Community Living Centers (CLC) to adjust how mental health (MH) care is provided. Beginning March 2020, admissions and staff entering CLC space were restricted in response to the pandemic. Some care shifted from in-person to virtual. Veterans were more isolated due to visitor restrictions and cancellation of communal activities. Pre-COVID, CLC teams cared for an

already complex population – 80% of residents had a MH diagnosis (24% with serious mental illness). Changing resident composition and increased isolation may intensify challenges in providing MH care. Using VHA administrative data, we assess the impact of the changing CLC environment during the pandemic by comparing monthly average rates of MH diagnoses and provision of MH care and as-needed psychotropics to CLC residents pre-COVID (Oct 2019 – Feb 2020) to the COVID period (Mar 2020 – Feb 2021). CLCs experienced a 26% decline in the monthly resident census. However, the monthly percentage of residents with a serious mental illness increased 13%. Pre-COVID, virtual MH encounters were received by 2% of residents; 35% received an in-person MH encounter. During COVID, 8% received a virtual MH encounter and 33% received in-person. As-needed antipsychotics remained unchanged, while as-needed benzodiazepine prescriptions decreased 15%. Despite increased MH concerns, CLC teams did not appear to respond with increased pharmacological interventions. Rather, teams seem to have maintained clinical service connection for those with MH concerns. Documenting successful approaches for addressing MH needs during this challenging time will be instructive for future care during times of crisis.

DISCRIMINANT COVID-19 OUTCOMES BASED ON SAFETY ADHERENCE IN AN ACTIVE LIFESTYLE RETIREMENT COMMUNITY

Mitchell Roberts,¹ Erica Sappington,² Leonardo Guerra,³ Lindsey Collins,³ Ali Yalcin,⁴ Carla VandeWerd,³ and Jeff Lowenkron,⁵ 1. *University of Florida, Tampa, Florida, United States*, 2. *University of South Florida, University of South Florida, Florida, United States*, 3. *University of Florida, University of Florida, Florida, United States*, 4. *University of South Florida, Tampa, Florida, United States*, 5. *The Villages Health, The Villages, Florida, United States*

Compliance with preventive behaviors recommended by public health officials plays a critical role in the control and prevention of COVID-19. Data were collected from those living in The Villages, FL, and surrounding communities via The Villages Health COVID-19 Rapid Testing Program in partnership with The UFHealth Precision Health Research Center. A descriptive ecological study was conducted to model COVID-19 positivity result variations by age, sex and adherence to CDC safety recommendations using chi-square tests. 9,993 tests were performed using Abbott's BinaxNOW™ COVID-19 Ag Card, and 931 (9.30%) positive cases were confirmed between 10/19/2020-2/26/2021. Median age was 69 years (range:12-103), and 5,578 (55.8%) individuals were female. No significant differences were found in positive test status ($\geq 65=9.8\%$, $<65=8.8\%$) amongst those over 65 ($n=6567$) and under 65 ($n=3180$) years old [$X^2(1, N=9847)=2.49, p=.114$]; however, positive test result differed by sex with males (10.6%) testing positive at higher rates than females [8.3%, $X^2(1, N=9993)=14.888, p<.001$]. A significant relationship between preventative behaviors and positive test status was also found. Not engaging in regular handwashing ($p<.001$) and failing to stay 6 feet or more away from others outdoors ($p<.001$) was significantly associated with positive test status. Further, not wearing a face mask in businesses/shops ($p<.001$) or indoors around 6+ people, ($p<.001$) was significantly associated with

positive test status. In light of debate around the efficacy of mask wearing, these findings signal the importance of following CDC recommended public health behaviors for all ages across the lifespan to reduce the spread of COVID-19 infection.

EARLY DOCUMENTATION OF LIFE-SUSTAINING TREATMENT ORDERS PRIOR TO DIAGNOSIS OF COVID-19 IN NURSING HOME RESIDENTS

David Henkin,¹ Brande Harris,² Sara Espinoza,³ Hazel Caliz,⁴ Kimberly Oakman,⁴ Sandra Sanchez-Reilly,⁵ and Marcos Restrepo,⁵ 1. *University of Texas HSC at San Antonio, Detroit, Michigan, United States*, 2. *South Texas Veterans Health Care System, South Texas Veterans Health Care System, Texas, United States*, 3. *University of Texas Health Science Center San Antonio, San Antonio, Texas, United States*, 4. *South Texas Veterans Health Care System, San Antonio, Texas, United States*, 5. *University of Texas HSC San Antonio, San Antonio, Texas, United States*

Coronavirus disease 2019 (COVID-19) has had a devastating impact on older adult nursing home residents (NHR). NHRs comprise greater than one-third of COVID-19 U.S. deaths, emphasizing the importance of engaging in end-of-life discussions. At South Texas Veterans Health Care System (STVHCS), we implemented early documentation of patient's Life-Sustaining Treatment (LST) or end-of-life goals-of-care preferences prior COVID-19 infection. We now aim to examine the association between early LST documentation (prior to COVID-19 diagnosis) and hospital admissions for COVID-19 by conducting a retrospective cohort study of Veteran NHRs at STVHCS from March 2020-January 2021. Inclusion criteria were NHRs with COVID-19 diagnosis, LST documentation, and clear timing of whether the LST documentation occurred before or after COVID-19 diagnosis. Logistic regression was used to determine the likelihood of hospitalization by whether LST was documented before or after COVID-19 diagnosis. 208 NHRs were diagnosed with COVID-19 and 160 (76.9%) had LST documentation. Of these, 148 were included in the analysis: 84 (56.8%) had a completed LST note prior to diagnosis and 64 (43.2%) after diagnosis. The hospitalization rate was 46% for those with LST prior to diagnosis compared to 78% in those with LST after diagnosis (OR = 0.24, 95% CI: 0.12-0.50, $P<0.001$), showing that early LST documentation was associated with 76% lower likelihood of hospitalization. Early interventions for LST documentation can reduce hospitalization in high-risk populations. These findings may have implications for reducing unnecessary hospitalizations, diminishing healthcare costs, and resolving ethical dilemmas related to potential resource allocation during a pandemic.

EFFECT OF RACE AND DEMENTIA PREVALENCE ON A COVID-19 INFECTION CONTROL INTERVENTION IN MASSACHUSETTS NURSING HOMES

Alyssa Dufour,¹ Cyrus Kosar,² Vincent Mor,² and Lewis Lipsitz,¹ 1. *Hebrew SeniorLife, Boston, Massachusetts, United States*, 2. *Brown University, Providence, Rhode Island, United States*

Nursing home (NH) residents, especially those who were Black or had dementia, had the highest infection rates during the COVID-19 pandemic. A 9-week COVID-19 infection

control intervention in 360 Massachusetts NHs showed that adherence to an infection control checklist with proper PPE use and cohorting, was associated with declines in weekly infection rates. NHs were offered weekly webinars, answers to infection control questions, resources to acquire personal protective equipment, backup staff, and SARS-CoV-2 testing. We asked whether the effect of this intervention differed by racial and dementia composition of the NHs. Data were obtained from 4 state audits using infection control checklists, weekly infection rates, and Minimum Data Set variables on race and dementia to determine whether adherence to the checklist competencies was associated with decline in average weekly rates of new COVID-19 infections. Using a mixed effects hurdle model, adjusted for county COVID-19 prevalence, we found that the overall effect of the intervention did not differ by race, but proper cohorting of residents was associated with a greater reduction in infection rates among facilities with $\geq 20\%$ non-whites ($n=83$). Facilities in the middle (50-61%; $n=116$) and upper ($>61\%$; $n=118$) tertiles of dementia prevalence had the largest reduction in infection rates as checklist scores improved. Cohorting was associated with greater reductions in infection rates among facilities in the middle and upper tertiles of dementia prevalence. Thus, adherence to proper infection control procedures, particularly cohorting, can reduce COVID-19 infections, even in facilities with high percentages of high-risk residents (non-white and dementia).

HOSPITAL IN HOME COVID-19 MONITORING: A NOVEL APPROACH TO KEEPING A WATCHFUL EYE ON OLDER ADULTS

Alissa Cooney,¹ Monica Serra,² Monica Lee,³ Kimberly Oakman,³ Laura Medlin,³ Sunil Ahuja,¹ Marcos Restrepo,¹ and Sandra Sanchez-Reilly,¹ 1. *University of Texas HSC San Antonio, San Antonio, Texas, United States*, 2. *UT Health San Antonio - Barshop Institute, San Antonio, Texas, United States*, 3. *South Texas Veterans Health Care System, San Antonio, Texas, United States*

Older adults suffering from severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) are at increased risk of death and hospitalization-related complications. The coronavirus disease 2019 (COVID-19) pandemic has forced adaptations in Telehealth, allowing COVID-19 patients to be managed at home. Traditionally, Hospital in Home (HIH) patients have better clinical outcomes and lower mortality compared to similar hospitalized patients. However, effectiveness of HIH for COVID-19 older adults remains unknown. This study examines the effect of age on rates of hospital readmission and overall mortality for patients enrolled in HIH after initial COVID-19 hospital discharge. A HIH COVID-19 monitoring program was developed to facilitate earlier hospital discharge and monitoring. Retrospective data between March 2020 and January 2021 were analyzed. Of the 402 subjects (age:26-99; mean:61.8), 13 (6.1%) subjects <65 years old vs 19 (10%) subjects ≥ 65 years old were readmitted to the hospital at least once. Two (0.94%) subjects <65 years old and 12 (6.3%) subjects ≥ 65 years old died. Older adults were 1.719 times more likely to be re-hospitalized ($p=0.005$) and 7.153 times more likely to die ($p=0.017$) compared to younger adults. Age remains a significant predictor of hospital readmission and mortality in

subjects previously hospitalized for COVID-19 even when followed by monitoring programs like HIH. Further studies are needed to determine the best way to reduce hospital re-admission and mortality rates for older adults after initial COVID-19 hospital discharge.

HOW COVID-19 PANDEMIC CHANGED CONSUMPTION OF FRUITS AND VEGETABLES BY OLDER ADULTS

Lillie Monroe-Lord,¹ and Azam Ardakani,² 1. *University of the District of Columbia, Washington, District of Columbia, United States*, 2. *Howard University, Howard University, District of Columbia, United States*

This study aims to determine the changes in consumption of fruits and vegetables of older adults before and since the COVID-19 pandemic. The data collection was administered by Qualtrics through an online survey conducted in August and September 2020. The total participants were 10,050. Differences between consumption of fruits (fresh, canned, frozen) and vegetables (carrots, sweet potatoes, broccoli, spinach) before and since COVID-19. Data were analyzed using the Wilcoxon's signed-rank test. Among participants, 5,767 females (57.4%) and 4,283 males (42.6%) and the average age of 62.09 (SD=11.22). 7.1% were Asian ($N=701$), 4.3% were Hispanic ($N=429$), 14.1% were African Americans ($N=1393$), and 74.5% were White ($N=7,390$). For total participants, consumption of fruits decreased significantly ($p<0.001$) since COVID-19. The decrease in consumption of fruits was larger in females ($p<0.001$) than males ($p=0.026$). It is likely because consumption of fruits by males was already low before the pandemic at 27% of the amount consumed by females. The decrease in consumption of fruits was not statistically significant in Asian ($p=0.096$) and African American ($p=0.07$), but significant in Hispanic ($p=0.008$) and White ($p<0.001$) participants. African American and Hispanic participants consumed a lower number of fruits before the pandemic compared to Asian and White participants. Consumption of vegetables had no significant change since COVID-19 for total participants regardless of gender and race. This study reported a significant decrease in the consumption of fruits, but not vegetables by older adults since COVID-19 pandemic.

IMPACT OF COVID-19 ON OLDER ADULTS: CHANGES IN HEALTH ACCESS, HEALTH, SOCIALIZATION AND ADAPTIVE COPING ACTIVITIES

Judith Scott, Stacy Yun, and Sara Qualls, *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*

Indirect effects of stay-at-home guidelines may negatively affect mental health by reducing health self-care behaviors and engagement in social participation. This study reports on the impact of the COVID-19 pandemic on community-dwelling older adults' perceived physical and mental health and everyday health behaviors. 126 older adults participated in a county-wide telephone survey during June-July of 2020, asking about changes in mental and physical health, and adaptations in health behaviors. We investigated the effects of three negative everyday health behavior changes during the pandemic (changes in health services access, perceived changes in health, and increased social isolation) as well as two positive

everyday health behaviors (adherence to stay-at-home guidelines to reduce risk, and adaptive coping activities) on mental health and COVID-related distress. Examples of active coping strategies were stockpiling resources, spiritual practices, or outreach to others. Descriptive statistics, bivariate correlations, and multiple regressions characterized the impact of COVID-19 on perceived mental health. Descriptive data included changes in health service access, changes in mental and physical health, reduced social engagement, increased adherence to guidelines, and increased adaptive coping activities. Significant predictors of mental health impact of the pandemic were changes in health service access ($\beta = .18, p < .05$), health changes ($\beta = .25, p < .01$), and adaptive coping activities ($\beta = .21, p < .05$). Findings suggest COVID-19 distress may be alleviated with improved health care access and increased social contact. Mental health challenges may also benefit from increased engagement in adaptive coping activities.

IMPACT OF THE COVID-19 PANDEMIC ON PARTICIPATION IN COMMUNITY-DWELLING OLDER ADULTS: A CROSS-SECTIONAL ANALYSIS

Khang Nguyen,¹ Luciana Macedo,² Brenda Vrkljan,² Renata Kirkwood,² Jinhui Ma,² and Marla Beauchamp,²
 1. *McMaster University, Hamilton, Ontario, Canada,*
 2. *McMaster University, McMaster University, Ontario, Canada*

Public health guidelines to prevent spreading COVID-19 place older adults at risk of loneliness and social isolation. Evidence suggests that participation protects older adults from such detrimental outcomes, therefore we aimed to identify the factors associated with participation in life roles among older adults living in the community during the COVID-19 pandemic. We conducted a telesurvey on a random sample of community-dwelling older adults living in Hamilton, Ontario, Canada, between May and July 2020. Outcome measures included participation in life roles, physical function, physical activity, mobility, mental health, nutrition, and demographics. We conducted two multivariate regression analyses with the Late Life Disability Instrument's (LLDI) frequency and limitations scales as the dependent variables. Candidate factors were organized by International Classification of Functioning, Disability, and Health (ICF) framework domains; personal factors, body functions and structures, activities, and environmental factors. A total of 272 older adults completed the telesurvey (mean age 78 ± 7.3 yrs, 70% female). Age, using walking aids, driving status, household income, education, mental health, nutrition, physical function, and dwelling type explained 47.1% ($p < 0.001$) of the variance observed in LLDI frequency scores. Using walking aids, driving status, receiving health assistance, mental health, and physical function explained 33.9% ($p < 0.001$) of the variance observed in LLDI limitation scores. These findings highlight factors from multiple ICF domains that are associated with participation limitation and frequency among older adults during the pandemic. Our findings have implications for developing public health initiatives to mitigate the effects of the pandemic on the participation of older adults.

LONELINESS AMONG US ADULTS DURING THE EARLY PHASE OF THE COVID-19 PANDEMIC: FINDINGS FROM THE COVID-19 COPING STUDY

Brendan O'Shea,¹ Jessica Finlay,² Jasdeep Kler,² Carly Joseph,³ and Lindsay Kobayashi,² 1. *University of*

Michigan, Lincoln, Nebraska, United States, 2. University of Michigan, Ann Arbor, Michigan, United States, 3. Central Michigan University, Ann Arbor, Michigan, United States

We aimed to estimate the prevalence of loneliness and identify the key sociodemographic, employment, living, and health-related risk factors for loneliness among middle-aged and older adults during the early COVID-19 pandemic in the US, when shelter-in-place and social distancing restrictions were in place for much of the country. Data were collected from online questionnaires in the COVID-19 Coping Study, a national study of 6,938 US adults aged 55-110 years, from April 2nd through May 31st, 2020. We estimated the population-weighted prevalence of loneliness (scores of $\geq 6/9$ on the 3-item UCLA Loneliness Scale), overall and according to sociodemographic, employment, living, and health-related factors. We used population-weighted modified Poisson regression models to estimate prevalence ratios (PRs) and 95% confidence intervals (CIs) for the associations between these factors and loneliness, adjusted for age, sex, race, ethnicity, and education. Overall, 29.5% (95% CI: 27.9%, 31.3%) of US adults aged 55-110 were considered high in loneliness in April and May, 2020. In population-weighted, adjusted models, loneliness was most frequent among those with depression, those who were divorced or separated, those who lived alone, those diagnosed with multiple comorbid conditions, and individuals who were unemployed prior to the pandemic. In conclusion, we identified subpopulations of middle-aged and older US adults that were highly affected by loneliness during a period when COVID-19 shelter-in-place orders were in place across most of the country. These insights may inform the allocation of resources to mitigate loneliness during times of restricted activity.

THE EFFECT OF TESTING TURNAROUND TIME ON COVID-19 OUTBREAK SEVERITY WITHIN U.S. NURSING HOMES

Annie Rhodes, Leland Waters, Faika Zanjani, Tracey Gendron, and Rick Moore, *Virginia Commonwealth University, Richmond, Virginia, United States*

COVID-19 has brought renewed attention to infectious diseases in U.S. nursing homes (NHs). The Testing turnaround time (TAT) of SARS-CoV-2 is vital information, supporting staff ability to make decisions regarding resource allocation. Methods: Using data obtained from the National Healthcare Safety Network's COVID-19 nursing home data set, we analyzed the TAT of laboratory polymerase chain reaction (PCR) testing on outbreak severity (number of people infected) for residents and staff. A MANOVA was performed on NHs submitting data over 26 weeks (May-November 2020). The independent variable was the average TAT for the two weeks prior (<24 hours, 1-2 days, 3-7 days, or 7+ days). Results: $N = 15,363$ NHs. The TAT for the combined dependent variables of staff and resident COVID-19 cases. $F(10,781,354) = 3161.265$, Pillai's trace = .078, $p < .0005$, partial $\eta^2 = .4$. The average outbreak severity for staff was 13.93 cases when TAT was < 24 hours, compared to 15.29 cases at 1-2 days. For residents, the difference was less pronounced but still significant. The average outbreak severity for residents was 17.07 cases when TAT was <24 hours, compared to 18.61 cases when the TAT was 1-2 days. Tukey post-hoc tests found significance for all levels of testing for residents and staff at $p < .0005$. Discussion: Time differences to receive

PCR test results from a laboratory are significant in outbreak severity for staff and residents. The most meaningful result positively impacting the ultimate spread and severity of gross cases is when the TAT for PCR results is < 1 day.

THE IMPACT OF COVID-19: PERSPECTIVES OF RECREATIONAL THERAPISTS WORKING WITH OLDER ADULTS

Betsy Kemeny,¹ and Dawn DeVries,² 1. *Slippery Rock University, Grove City, Pennsylvania, United States*, 2. *Grand Valley State University, Grand Rapids, Michigan, United States*

This study explored the perspectives of recreational therapists (RT) from Pennsylvania and Michigan and how COVID-19 has impacted older adults and their roles in various settings. COVID-19 safety restrictions limiting social interaction with both peers and families had the potential for negatively impacting the social and emotional well-being of older adults (Van Orden et al., 2020) and the roles of therapists who work with them. Because peer socialization and physical activity programs prevent falls (Cameron et al., 2018) and improve depressive symptoms (Harvey et al., 2015), a better understanding of COVID-19 impact is significant. From a qualitative viewpoint, 14 RTs from various levels of care were interviewed to better understand their perspective on the impacts of COVID on older adults and their own practice. Hour long interviews conducted via zoom focused on organizational changes, role changes, and impact on older adults. After recordings were transcribed, multiple researchers classified, summarized, and tabulated the data. A consensus method determined common themes. From the RT's perspective, older adults have not only been negatively impacted in the social domain. While many older adults showed resilience, others were impacted physically, emotionally, and cognitively. Moreover, an increased importance on meaningful engagement, recreation, and leisure emerged. Technology became an essential tool in interpersonal connection. Teamwork, personal self-care, and coping were integral to providing effective care. Post pandemic, RTs are concerned about the challenge of reengaging older adults in groups but are certain that technology will continue to be used in a more expansive way in programs.

THE LIVED EXPERIENCE OF ASSISTED LIVING ADMINISTRATORS DURING THE COVID-19 PANDEMIC

Elizabeth Hill, Rebecca Davis, Paige Greer, and Susan Strouse, *Grand Valley State University, Grand Rapids, Michigan, United States*

Since March, 2020, administrators in assisted living (AL) residences have been challenged to provide the best care for their populations while undergoing a pandemic. Because nothing like this has happened in the recent past, AL administrators had to make many new decisions. The purpose of this phenomenological study is to reflect on the lived experiences of AL administrators during the COVID pandemic. Using a semi structured interview, individual interviews of four AL administrators from different AL communities were conducted via Zoom. The interviews contained questions related to the participants' experiences with the COVID-19 pandemic. The recorded interviews were transcribed verbatim into MAXQDA. Data analysis followed a modified Giorgi approach, by reviewing the recorded interviews,

categorizing the data into meaning units, then situated units, generalized units, and then themes. Results indicated that AL administrators have been adapting to constantly changing and conflicting regulations. The pandemic incited fear, depression, moral distress, but also hope for the future. The data shows a multitude of feelings and actions related to the well-being of the staff, residents, and residents' families. The limitations of this study include a small sample size and the evolving nature of the pandemic in Michigan. Opportunities for future research would be to compare our findings to the experience of other ALs in the United States. The results show the complexity of AL administrators' lived experiences during the pandemic and highlight important considerations if an event like the pandemic were to occur again.

TIMELINE OF COVID-19 INCIDENCE AND MORTALITY AMONG RESIDENTS AND STAFF OF SOUTH CAROLINA LONG-TERM CARE FACILITIES

Matthew Lohman,¹ Nicholas Resciniti,² Morgan Fuller,¹ and Joshua Sellner,³ 1. *University of South Carolina, Columbia, South Carolina, United States*, 2. *University of Southern California, Los Angeles, California, United States*, 3. *South Carolina Department of Health & Environmental Control, Columbia, South Carolina, United States*

The COVID-19 pandemic has disproportionately impacted older adults living in long-term care facilities (LTCFs), but little research has described parallel infection rates and mortality among LTCF residents and staff in relation to state-level mitigation measures. This study used comprehensive COVID-19 tracking data from the South Carolina Department of Health and Environmental Control (SCDHEC), including case report information on demographics, symptoms, comorbidities, and employment. We included all confirmed or probable COVID-19 cases and deaths among adult SC residents reported between 3/15/2020 and 1/2/2021. Residence or employment in LTCF, including nursing homes, assisted living, or skilled nursing facilities, were confirmed by SCDHEC. Cox proportional hazards models were used to compare mortality between residents/staff and counterparts in the community. Overall, 54,514 cases of COVID-19 were identified among older adults in SC. Of these, 13.5% (n = 7,366) resided in a LTCF. LTCF residents with COVID-19 were more likely to be hospitalized compared to older adults in the community and 74% more likely to die (HR= 1.74, 95% CI: 1.59-1.90), after controlling for age, gender, race, and chronic health conditions. LTCF staff had greater infection rates but lower risk of mortality (HR=0.58; 95% CI: 0.39-0.88) compared to the general population. Differences in COVID-19 incidence and mortality between residents/staff and the community decreased after statewide mitigation policies. This study indicates that LTCF residents are at increased risk of COVID infection and mortality, even accounting for pre-existing health conditions. LTCF settings are key sites for prioritizing prevention, vaccination, and training plans to prepare for future pandemics.

TRANSFERS AMONG LONG-TERM NURSING HOME RESIDENTS DURING THE COVID-19 PANDEMIC

Ana Montoya,¹ Chiang-Hua Chang,² Pil Park,² and Julie Bynum,¹ 1. *University of Michigan, Ann Arbor, Michigan, United States*, 2. *University of Michigan, Ann Arbor, Michigan, United States*

Transferring long-term nursing home residents between facilities can compromise the quality of life and be associated with functional decline, hospitalizations, and even death. This study aimed to examine transfer rates and identify risk factors associated with transfers among long-term nursing home residents before (2018-2019) and during the COVID-19 pandemic (2020). Using the Michigan state Minimum Data Set data 2018-2020, we identified long-term residents as those who stayed in nursing homes for at least 100 days each year (N=39,693, 39,454, and 35,575, respectively). We defined a facility-to-facility transfer as a direct transfer between two nursing homes. We first examined the likelihood of transfer by year using logistic regression models, adjusting for residents' age, sex, race, and marital status. We then examined two health statuses that could be associated with a transfer: activities of daily living (ADL) and cognitive impairment. Finally, we compared transfers that occurred before COVID-19 (2018-2019) and during COVID-19 (2020), adjusting for residents' demographic characteristics and health statuses. After adjustment, age was the only factor associated with transfers for all three years (Age \geq 80: AOR=0.61, 95% CI: 0.54-0.69; AOR=0.63, 95% CI: 0.55-0.72; AOR=0.71, 95% CI: 0.63-0.80, respectively). New risk factors in 2020 were Black race (AOR=1.22, 95% CI: 1.07-1.40) and requiring ADL assistance (AOR=1.24, 95% CI: 1.03-1.49). The COVID-19 period had higher transfer rate (unadjusted rates 2.9%, 2.7%, 3.5%, respectively) with 10% higher odds of transfer compared to before COVID-19 (AOR=1.10, 95% CI: 1.01-1.20). This finding suggests that COVID-19 has an impact on how nursing home transferred their long-term residents.

TRENDS IN DELIRIUM RATE ACROSS 14 HOSPITALS DURING THE COVID-19 PANDEMIC: A COMPARATIVE STUDY.

Ariba Khan,¹ Marianne Klumph,² Alexander Schwank,² Michael Malone,² and Asma Sabih,² 1. *Advocate Aurora Health Care, Milwaukee, Wisconsin, United States*, 2. *Advocate Aurora Health, Milwaukee, Wisconsin, United States*

During the COVID-19 pandemic, strategies to prevent delirium in the hospital were limited due to restrictions in staff and visitor policies. Thus, we suspected the delirium rate may increase during the pandemic. This study aimed to investigate the trends in delirium rate over past 2-years and compare this trend prior-to-and-during the COVID-19 pandemic in hospitalized older adults. Data was retrospectively obtained from the Acute-Care-for-Elders Tracker snapshot, an electronic health record tool to identify the presence of delirium within 48hrs of hospitalization for patients \geq 65 years. Periods of interests were 3/2019-6/2019 (pre-COVID) and 3/2020-6/2020 (during-COVID). A weighted rate was calculated for each month by combining data from all hospitals for the total number of inpatients \geq 65 years. The overall trend in the delirium rate was assessed with simple linear regression models and an ANCOVA. A χ^2 and a Wilcoxon-Signed-Rank-Test were utilized to test for differences in the overall delirium rate between two time periods. Overall median delirium rate was 6.8% in 70,562 encounters of 42,878 patients (mean age= 78 years; mean length-of-stay= 6.5 days). The median delirium rate increased by

2.1% (6.6%to8.6%), for pre-COVID vs. during-COVID, respectively (Z=-3.044,p<0.001). There were no significant differences between actual and projected weighted delirium rates (p=0.18). However, the weighted delirium rate—for both the actual and projected trend lines—demonstrated significant changes over time (p<0.001). The trend in delirium rate increased over the study time period regardless of the pandemic. Further analyses with longer time-frame are crucial to understand the consequences of the pandemic on delirium rate.

VARIABLES IMPACTING NURSING HOME GOALS OF CARE DISCUSSIONS AND ORDER IMPLEMENTATION DURING COVID-19

Orah Burack,¹ Joann Reinhardt,¹ Wingyun Mak,¹ Himali Weerahandi,² Benjamin Canter,³ and Kenneth Boockvar,¹ 1. *The New Jewish Home, New York, New York, United States*, 2. *NYU Grossman School of Medicine, New York, New York, United States*, 3. *The New Jewish Home, The New Jewish Home, New York, United States*

Nursing home (NH) residents are especially vulnerable to COVID-19, disproportionately suffering from severe illness and death. As such, resident Goals of Care (GOC) often had to be quickly established to ensure treatment preferences were known and respected. This study examined variables related to the occurrence of GOC discussions and added orders (Do Not Resuscitate, Do Not Intubate, and Do Not Hospitalize), including demographic, physical functioning, cognitive impairment, depression, number of diagnoses, and Optum participation (Optum provided added specialized care by nurse practitioners who routinely address GOC preferences). Subjects were 286 COVID positive residents from a large NYC NH. All data were obtained from the NH's electronic medical records. Patient median age was 81 n (interquartile range 71-88), 59% were female, 61% were long stay (stay >100 days) and 39% were short stay. Using bivariate correlations we found that older short stay residents were more likely to have GOC conversations. Additionally, older, cognitively impaired, Optum participants were more likely to have orders added. When all independent variables were entered into binary logistic regressions, only older age and being a primary English speaker were significantly related to the occurrence of GOC conversations ($\chi^2=21.76^{**}$; N=278; Nagelkerke R² = .10), while older age and being an Optum participant were related to added orders ($\chi^2=32.18^{**}$; N=164; Nagelkerke R² = .24). Results have implications for (1) ensuring the GOC wishes of diverse populations are known and abided by and (2) improving the quality of clinician – resident GOC discussions.

VIDEO CHAT USE AND MEALTIME BEHAVIORS IN OLDER ADULTS BEFORE AND DURING THE COVID-19 PANDEMIC

Laura Barre,¹ Tara Young,² and Sarah Coupal,² 1. *Cornell University, Ithaca, New York, United States*, 2. *Cornell University, Cornell University, New York, United States*

Video chat allows people to connect when not physically together. Using video chat while sharing a meal (VideoDining) may decrease loneliness and improve older adults' nutritional intake. We conducted a cross-sectional online survey study using Amazon Mechanical Turk in June 2020. The

objectives were to learn about eating with others, the use of video chat, and interest in VideoDining in older adults during the pandemic. There were 1331 survey attempts with 167 responses meeting the criteria for age (65 years of age or older), U.S. residency, and quality. Participants were 64% male, 77% white, 65% college-educated, and a median age of 67 years (IQR=2 years). Few participants lived alone (17%), yet 76% reported feeling isolated. Eating with others regularly, defined as several times a week or more, declined in the pandemic (44% vs. 59% pre-pandemic, $p=0.0002$). The use of video chat and eating when video chatting increased during the pandemic versus pre-pandemic (82% vs. 74%, $p=0.003$; 47% vs. 37%, $p=0.0005$). The majority of participants said they would VideoDine (50%) or consider trying it (37%). Interest in VideoDining did not vary by age, race, or gender. Participants who used video chat were more likely to say they would VideoDine than participants who had never used video chat (OR=3.1; 95% CI=1.25, 8.35; $p=0.02$). This data suggests most adults 65 years of age and older, already using the Internet, are experiencing isolation and decreased mealtime commensality during the pandemic. The vast majority are using video chat and are interested in trying VideoDining.

VIRAL CULTURE IN HOSPITALIZED CONGREGATE CARE PATIENTS WITH PROLONGED SARS-COV-2 VIRAL RNA DETECTION

Thilaka Arunachalam,¹ Amit Singh,² Kathleen Stellrecht,³ Sarah Elmendorf,⁴ Tarani K. Barman,⁵ Michael Robek,¹ Dennis W. Metzger,¹ and Michael Waxman,⁶ 1. Albany Medical College, Albany, New York, United States, 2. Albany Medical Center, ALBANY, New York, United States, 3. Albany Medical Center, Albany, New York, United States, 4. Albany Medical Center, Albany Medical Center, New York, United States, 5. Albany Medical Disease, Albany, New York, United States, 6. Albany Medical College, Albany Medical College, New York, United States

Prolonged detection of SARS-CoV-2 viral RNA has been observed in hospitalized congregate care patients following resolution of clinical symptoms. It is unknown whether patients with persistent PCR positivity pose a risk for COVID-19 transmission. The purpose of this study was to examine the results of serial PCR testing, viral load, and viral culture in patients awaiting discharge prior to a negative PCR test. We sampled 14 patients who were admitted from skilled nursing and/or rehabilitation facilities to a large academic medical center, had clinical signs and symptoms of COVID-19, and had multiple PCR-positive tests separated by at least 14 days. PCR-positive nasopharyngeal swabs were obtained from each patient for viral load quantification and viral culture. The mean age of patients was 72.5 years (55 – 92), with a mean peak SOFA score of 5.6 (1 – 11). Patients were hospitalized for a mean of 37.0 days (25 – 60). RNA was detected by PCR for a mean of 32.9 days (19 – 47). Mean viral load for the first PCR-positive nasopharyngeal swab collected at our hospital was 5.81 genomic copies/mL (2.12 – 9.72). Viral load decreased significantly with days from clinical symptom onset ($R = -0.69$, 95% CI, -0.80 – -0.55). Four out of 28 samples grew active virus via culture, with no active virus isolates after 2 days of symptom onset. Our viral culture data suggests that persistent PCR positivity may not correlate with

infectivity, which has important implications for COVID-19 infection control precautions among older congregate care patients.

COVID-19 Pandemic

Session 9165 (Poster)

“HUNGER WOULD KILL US INSTEAD OF THE PANDEMIC:” ELDERS’ RESPONSES TO COVID-19 IN ETHIOPIA

Messay Kotecho,¹ Anduamlak Takele,² and Margaret Adamek,³ 1. Addis Ababa University, Addis Ababa, Adis Abeba, Ethiopia, 2. Debre Markos University, Debre Markos, Dire Dawa, Ethiopia, 3. Indiana University, INDIANAPOLIS, Indiana, United States

The COVID-19 pandemic has posed unpredictable challenges globally. Urban elders in Global South nations are among the major population groups vulnerable to COVID-19. A qualitative case study design was used to uncover the challenges and sources of support for poor urban elders during COVID-19 lockdown in Ethiopia. Data were collected from 27 elders age 60 and above in Debre Markos Town via in-depth interviews and document review. Narrative data were analyzed using thematic data analysis. Four prominent themes were identified: 1. Food insecurity (“Hunger would kill us instead of COVID-19”), 2. Hopelessness (“Feeling hopeless and begging to die”), 3. Social isolation (“We prefer social support rather than food donations”) and 4. Gratitude (“Feeling thankful”). The physical distancing program introduced to contain the pandemic isolated many elders and diminished their capacity to access support from others needed to perform their daily activities. An institutional welfare system is needed to ensure older adults in the Global South can live a joyful and dignified life, even through a global pandemic. Moreover, a special emergency fund to meet older adults’ basic needs during a pandemic like COVID-19 should be introduced to minimize the effect of crises on vulnerable groups like destitute older adults in Ethiopia.

ADAPTABILITY OF OLDER ADULTS AT THE ONSET OF THE COVID-19 PANDEMIC

Laurie Blackman,¹ Donna Wang,² Kathryn Kruse,³ Joyce Roberson-Steele,³ Annette Clarke-Jones,³ and Latoya Attis,³ 1. Yeshiva University, Wurzweiler School of Social Work, Silver Spring, Maryland, United States, 2. Springfield College, Springfield College/Springfield, Massachusetts, United States, 3. Yeshiva University, Yeshiva University/New York, New York, United States

It is important to understand the unique experiences and perspectives of older adults who were required to incorporate critical adjustments to behavior during the onset of the COVID-19 pandemic. An anonymous, cross sectional survey was administered online through Qualtrics Survey Software in June 2020. The results of this study found that older adults utilized different sources of information than younger adults; they were more likely to read the newspaper or listen to the radio, and less likely to rely on social media for information. Older respondents in this study reported coping with the COVID-19 outbreak better than younger respondents,

were less likely to report that they were personally affected by the virus, and less likely to feel overwhelmed by the amount of information about COVID-19. The findings of this study highlight resilience in older adults not found in younger adults, and provide an important step in identifying policy and practice suggestions to reduce negative repercussions for older adults experiencing the current crisis, as well as future generations of older adults who might experience similar events.

EXPLORING CAREGIVER CHALLENGES AND COPING MECHANISMS IN THE MIDST OF COVID 19

Devyani Chandran,¹ and Marie Eaton,² 1. *Western Washington University, Redmond, Washington, United States*, 2. *Western Washington University, Western Washington University, Washington, United States*

This paper reports on the the challenges faced and coping strategies employed community-based care providers in a mid sized city in the Pacific Northwest in the midst of the Covid 19 pandemic. Researchers from a Palliative Care Institute conducted six online focus groups using the zoom platform. The project aimed at gathering important information on the experiences of caregivers as well as providing a virtual space where caregivers could support each other. A purposive sampling technique was used to gather data where participants were not chosen randomly but because they could best answer the research question. Membership of the focus groups included representatives from skilled nursing facilities, home-care agencies, elder law services, memory-care facilities, adult family homes, medical supply facilities, chaplains and nutritionists. Data gathered from the focus group were transcribed. A constant comparison method of analysis were employed and categories and themes were created from open coded data. Six key themes were identified which included: dealing with the impact of social isolation on caregiver-client relationships, assessing personal risk when dealing with clients living with dementia, facing challenges seeking continuing employment, struggling with social support and self care, using technology for professional and personal support and grappling with the challenges reentering a face to face environment once the pandemic is controlled.. Findings point to the importance developing and sustaining technological innovations that support workforce retention, fostering communication between the larger community, care providers and clients in various care settings and planning for safe reentry into a post Covid world.

HIGHER STAR, BETTER PERFORMANCE IN US NURSING HOMES DURING THE COVID-19 PANDEMIC ?

Lei Yu,¹ Xiao Qiu,¹ and Tara Rose,² 1. *Miami University, Oxford, Ohio, United States*, 2. *University of Southern California, Los Angeles, California, United States*

The Covid-19 pandemic has brought terrible difficulties to nursing homes, as they were locations with the highest number of confirmed Covid-19 cases and deaths in the US. The Centers for Medicare & Medicaid Services (CMS) applies the Five-Star Quality Ratings to indicate the quality of care in nursing homes based on health inspection survey, staffing, and resident outcome. Studies to date have contradictory findings regarding the relationship between nursing home reported Quality Ratings and Covid-19 cases and

deaths based on US regional data. The purpose of this study is to examine whether nursing homes' Quality Ratings were related to the total number of resident Covid-19 cases and deaths at the US National level. The study examined US nursing homes (N=13,494) linked with CMS Nursing Home Compare data and Covid-19 Nursing Home data. Using multiple linear regression analyses, results showed nursing home Quality Ratings were significantly associated with Covid-19 residents' cases and deaths controlling for ownership type, size, occupation rate, and years of operation ($p < .001$; $p < .001$). Five-star nursing homes were less likely to have Covid-19 cases and deaths. Further, comparing lower Star Ratings nursing homes, 1-Star nursing homes showed no significant difference to 2-Star and 3-Star nursing homes when examining Covid-19 cases and deaths. Overall, the Five-Star Quality Ratings is a useful measure when investigating nursing homes' performance during the Covid-19 pandemic. Future policymakers and administrators should also focus on nursing homes with lower star ratings when improving the quality of nursing homes, particularly with regard to resident health.

NO VISITORS ALLOWED! THE IMPACT OF COVID-19 RESTRICTIONS ON THE PSYCHOSOCIAL WELL-BEING OF NURSING HOME RESIDENTS

Shanae Shaw,¹ and Ellen Csikai,² 1. *Alabama State University, Calera, Alabama, United States*, 2. *The University of Alabama, The University of Alabama, Alabama, United States*

The COVID-19 coronavirus pandemic changed life for everyone, but especially for nursing home residents. In March 2020, the Centers for Medicare and Medicaid Services enacted nursing home restrictions in response to the pandemic regarding visitation from outside family/friends and changes to facility activity programs. Despite the public health concern prompting these restrictions to prevent virus spread, these sudden changes affected nursing home residents' relationships with their spouses/partners. As part of a larger study to identify the nursing home policies and practices that preserve relationships among nursing home residents with spouses/partners, participants shared facilities' restrictions, social connection practices, and effect of coronavirus restrictions on residents' relationships with spouses/partners. The study utilized both an online survey (81 respondents) and ten telephone interviews with nursing home social workers in four Southern states. Twenty-eight percent of participants reported that no visitors were allowed; while 25% allowed couples to visit with one another as usual was reported by 25%. The most noted practices to maintain social connections were phone calls, video calls, and 'window' visits between residents and families/friends; however, "it's just not the same. It's affected them greatly". The interviews revealed further details about the detrimental effect of the COVID-19 restrictions on nursing home residents' overall mental health and attachment relationships with spouses/partners. These results highlight the importance of maintaining social connections between residents and spouses/partners. Nursing home social workers can develop policies and practices that enhance relationships and connections under all circumstances and work with other health care team members to ensure implementation.

RELATIONSHIP BETWEEN SOCIAL DETERMINANTS OF HEALTH AND LONELINESS DURING COVID-19 PANDEMIC

Kalpna Padala,¹ Christina Crawford,² Clinton Gauss,² Benjamin Wright,² Olive Phillips,² Richard Dennis,² Hillary Lum,³ and Prasad Padala,² 1. *Central Arkansas Veterans Healthcare System, Central Arkansas Veterans Healthcare System, North Little Rock, Arkansas, United States*, 2. *Central Arkansas Veterans Healthcare System, North Little Rock, Arkansas, United States*, 3. *University of Colorado School of Medicine, Aurora, Colorado, United States*

Background: Older adults are most vulnerable to social isolation and loneliness during the COVID-19 pandemic compared to other populations. Risk factors for loneliness include old age, rural living, number of medical comorbidities, and poor social networks. The objectives of this study were to examine the prevalence of loneliness in older adults during COVID-19 and determine the correlation between social determinants of health and loneliness. **Methods:** A cross-sectional study was conducted in community dwelling older Veterans (N=132). Demographic data were collected along with variables related to social determinants of health. Loneliness data were collected with the 3-item loneliness questionnaire, and social network was assessed using the 6-item Lubben social network scale. **Results:** Demographic data included: mean age 73.3 (\pm 7.5) years, 93.2% male, 53.5% rural, 84.1% Caucasian, and 13.6% African American. The majority of the participants reported loneliness (65.6%). Mean Lubben social network score was 14.6 (\pm 6.6). There was a strong negative correlation between loneliness and social network ($p < 0.0001$, $r = -0.57$; 95% CI: -0.67, -0.44). The prevalence of loneliness was significantly greater in those living alone compared to those not living alone ($p = 0.017$; 83.9% vs. 60.6%) and those lacking internet access compared to those with internet access ($p = 0.025$; 86.4% vs. 61.5%). **Conclusion:** Loneliness was found to be highly prevalent in an older cohort during the COVID pandemic. Routine inquiry about loneliness is important. Social determinants of health are likely correlated with the presence of loneliness in older adults and could be greatly impacted by policy decisions made to control community disease transmission.

SPATIAL DISTRIBUTION OF COVID-19 AND COMORBIDITIES IN NEW ENGLAND

Chae Man Lee,¹ Taylor Jansen,¹ Shu Xu,² Maki Karakida,¹ Frank Porell,³ Nina Silverstein,⁴ and Elizabeth Dugan,¹ 1. *UMass Boston, Boston, Massachusetts, United States*, 2. *University of Massachusetts Boston, Dorchester, Massachusetts, United States*, 3. *University of Massachusetts Boston, University of Massachusetts Boston, Massachusetts, United States*, 4. *University of Massachusetts Boston, Boston, Massachusetts, United States*

At the onset of the COVID-19 pandemic, the Centers for Disease Control and Prevention (CDC) identified chronic conditions which elevated the risk of COVID-19 complications: chronic obstructive pulmonary disease (COPD), diabetes, heart disease, kidney disease, and obesity. The aim of this study is to visualize the spatial distribution of confirmed cases of COVID-19 and local rates of comorbidities in CT, MA, NH, and RI and to identify the spatial clustering of

hot spot between COVID-19 cases and rates of a summary measure of comorbidities across communities. This study collected data from state's departments of public health in 4 New England states of confirmed COVID-19 cases as of February 25th, 2021 and extracted community-level rates of comorbidities among adults age 65+ from recent Healthy Aging Data Report (www.healthyagingdatareports.org). Results showed that the cities Bridgeport, CT (n=14,637), Boston, MA (n=57,912), Manchester, NH (n=9,658), and Providence, RI (n=26,792) had the highest rates of COVID-19 and the highest population density. The GIS based map illustrated that the largest cities with the highest population densities had both relatively high incidences of COVID-19 and heavy burdens of comorbidities. This study found that the hot spot areas of COVID-19 were observed in communities with the highest chronic disease burdens. These hot spots of COVID-19 and comorbidities are areas where resources (testing, masks, vaccines) should be surged to protect the community. The identification of hot spots may motivate residents to take every mitigation step to prevent and control COVID-19.

THE SEASONS OF COVID-19: UNDERSTANDING THE MOOD OF OLDER ADULTS IN THE UK THROUGH A BAROMETER SURVEY SPANNING 12 MONTHS

Nicola Palmarini,¹ Alex Mitchell,² Lesley Hall,³ James McNaughton,³ and Charlotte Nixon,⁴ 1. *Newcastle University, Newcastle Upon Tyne, England, United Kingdom*, 2. *UK National Innovation Centre for Ageing, Newcastle upon Tyne, England, United Kingdom*, 3. *Newcastle University, Newcastle upon Tyne, England, United Kingdom*, 4. *UK's National Innovation Centre for Ageing, Newcastle, England, United Kingdom*

The impact of COVID-19 on older adults has been analysed through different research approaches. However, with its sudden global spread, combined with uncertainty about which countermeasures would be employed, there was a lack of opportunity to systematically and continuously engage in a system of observing the moods of older adults forced to live in unexpected conditions. Ageist narratives, social distancing, the unending barrage of real and fake news, and the lockdowns, have given rise to what we define as a series of "seasons" of life, characterised not by the weather barometer, but by moods of people. How much did these external events, like the impact of weather, affect the mood of older adults? We immediately recognised the pandemic's long-term nature, and thanks to our position as an "observatory" of social dynamics, and because of our existing community of older adults (VOICE), we could involve our members to provide valuable insights about mood and wellbeing during the pandemic. We initiated a weekly pulse survey, based on the two same questions, starting in week 13 of 2020. Across the 50 weeks which followed, we received 2577 responses. They rated their mood on a scale of 1 (extra-stormy) to 5 (all sunshine), before we collated the data and mapped on key events related to media announcements and political decisions. Our research showed the impact of these events on the mood of participants, and the potential of this approach to identify trends in mood to help policy makers with informed decision-making during unprecedented times.

TYPE 2 DIABETES MANAGEMENT AMONG OLDER BLACK AMERICAN MEN DURING THE COVID-19 PANDEMIC: A QUALITATIVE INVESTIGATION

Ledric Sherman,¹ DeLawnia Comer-HaGans,² and Sara Vera,¹ 1. *Texas A&M University, College Station, Texas, United States*, 2. *Texas Department of State Health Services, Austin, Texas, United States*

As COVID-19 swept across the globe in 2020, it appeared to have infected and killed Black Americans at a disproportionately higher rate. However, few studies have focused specifically on the complications of managing diabetes, expressly type 2 diabetes (T2D), among Black men during the global pandemic. Therefore, the purpose of this qualitative study was to seek understanding of the experiences in managing T2D among Black men during the COVID-19 pandemic. One on one interviews were conducted via Zoom video conferencing with twenty-two (n=22) Black men regarding their experience of managing type 2 diabetes (T2D) in a pandemic environment. Four main themes emerged from the study, which are: (1) stress levels during the pandemic, (2) barriers to managing my diabetes, (3) who/what is helping the most, and (4) communication with health-care provider. As more information becomes available, it is apparent that having diabetes increases the risk for detrimental COVID-19 outcomes (i.e. increased lengths of hospital stays, the need for mechanical ventilation, and mortality). Future research efforts are crucially needed to provide an improved understanding of how individuals across all racial groups are managing diabetes during the COVID-19 pandemic.

WE NEED TO PROTECT OURSELVES: THE MENTAL BURDEN OF MANAGING TYPE 2 DIABETES AMONG BLACK MEN DURING THE COVID19 PANDEMIC

Ledric Sherman,¹ Anthony Pattin,² Carla Pattin,² Michelle Strong,¹ and Sara Vera,¹ 1. *Texas A&M University, College Station, Texas, United States*, 2. *The University of Toledo, Toledo, Ohio, United States*

As COVID-19 swept across the United States in 2020, it appeared to infect and kill Black Americans at a disproportionately high rate. When examining the literature pertaining to the pandemic, present COVID-19 research focuses on physical health, but research regarding mental health and stress during the COVID-19 pandemic are lacking, especially among Black men and minority men in general. Therefore, the purpose of this study was to learn more about the type 2 diabetes (T2D) management related stress among Black men (n=22) during the COVID-19 pandemic. One on one interviews were conducted via Zoom video conferencing to gain an understanding of the experiences of managing T2D in a pandemic environment. Three main themes emerged from the study, which are: (1) my stress levels during this time, (2) diabetes specific stressors, and (3) coping mechanisms. Black men with diabetes may need psychosocial support that holistically addresses general developmental and diabetes-specific stressors and their influences on one another. Recognizing how Black men react to stress is essential for understanding and addressing their disproportionately high prevalence of stress related to management of chronic conditions and avoiding additional complications, morbidity or mortality. It is imperative to examine how stress and coping frameworks relate to men's health, in general, but specifically in Black men.

Session 9170 (Poster)

COVID-19 Pandemic and Education

A REMOTE MUSIC-BASED SERVICE-LEARNING PROJECT TO SUPPORT ISOLATED OLDER ADULTS IN LONG-TERM CARE

Emma King, and Alaine Reschke-Hernandez, *University of Kentucky, Lexington, Kentucky, United States*

Growth of the aging population warrants a commitment to teaching students to work effectively with older adults. In an online university course focused on inclusive music practices, students engaged in an extensive service-learning project to enhance course learning objectives and increase sensitivity to disability, social justice, and inclusion issues across the lifespan. Based on community needs, one student aimed to reduce isolation among older adults living in a long-term care facility. The student selected this target and population because of the detrimental effects of isolation on psychosocial, cognitive, and physical well-being; and reduced access to interactive programs and services among older adults living in residential facilities during the COVID-19 pandemic. Components of the project included a service-learning proposal, an annotated bibliography, an interview with the community partner, three activity designs, and a reflective essay. Based on existing research regarding interventions used to reduce isolation among older adults, the three activities the student designed were music bingo, interactive singing, and stretches to music. Throughout the service-learning process, the student consulted the community partner to ensure relevance of the activities. Principles of Universal Design for Learning (UDL), such as providing multiple visual and auditory means to engage with materials, enhanced accessibility of the activities. In this presentation, the student and course instructor will reflect on this case experience and the value of service-learning to foster professional skill development, engaged citizenship in working effectively with older adults, and an appreciation of the need for justice, equity, and fairness for all community members.

ASSESSING NEEDS, WELL-BEING, AND TELEHEALTH ACCESS OF OLDER ADULTS WITH LIMITED RESOURCES DURING COVID-19 PANDEMIC

Sashah Damier,¹ Assma Twahir,² Sweta Tewary,¹ Naushira Pandya,² and Nicole Cook,² 1. *Nova Southeastern University, Fort Lauderdale, Florida, United States*, 2. *NSU, Davie, Florida, United States*

The COVID-19 pandemic created new barriers and challenges to accessing primary care services, particularly among older adults who already faced barriers related to access to care, including transportation, health literacy, and self-management support. Nova Southeastern University South Florida Geriatric Workforce Enhancement Program (NSU SFGWEP) partnered with primary care clinics to conduct wellness calls to older adult patients identified through clinic EHR. The wellness calls' objectives were to 1) discuss COVID-19 protective measures; 2) assess wellness needs and access to care barriers; and 3) screen for telehealth support. From September 2020 to February 2021, the team (including medical students, public health students, and SFGWEP staff)

contacted 200 patients via telephone and conducted a comprehensive wellness survey developed by the study team, informed by validated surveys. Among the 200 patients called, 60% (n=34) were very concerned about the Covid-19 pandemic, 33% (n=34) reported often feeling isolated from others, and 20% (n=34) expressed difficulty getting medical care. A smaller subset of patients reported concern about limited COVID-19 testing (n=1), lack of knowledge about seeing their provider via telehealth (n=7), lack of face masks (n=1), and challenges with obtaining medication refills (n=1). Following wellness calls, the NSU SFGWEP team provided education, referred to clinical resources, and, for low-income patients with access to care challenges, provided Samsung Tablets (n=50) with peer training to enable telehealth.

COVID-19 AND AGE-FRIENDLINESS IN HIGHER EDUCATION

Celeste Beaulieu,¹ Nina Silverstein,¹ Lauren Bowen,² Susan Whitbourne,³ and Joann Montepare,⁴ 1. *University of Massachusetts Boston, Boston, Massachusetts, United States*, 2. *University of Massachusetts, Boston, University of Massachusetts Boston, Massachusetts, United States*, 3. *University of Massachusetts Boston, University of Massachusetts Boston, Massachusetts, United States*, 4. *Lasell University, Newton, Massachusetts, United States*

During the COVID-19 pandemic, universities have changed to an online or hybrid format. These changes provide the opportunity for universities to be more accessible for all individuals. However, the logistics of university life during a pandemic has exposed significant and potentially enduring challenges and opportunities for designing and maintaining an Age-Friendly University. This study investigates perceptions of students, faculty, and staff in the lens of an age friendly university during the COVID-19 pandemic. This study draws on qualitative and quantitative data from over 10,000 faculty, staff, students, and life-long learners from 26 universities. Five items were asked to constituent groups about their perceptions on their university's response to COVID-19. Overall, students had the poorest average perception of satisfaction with their university's overall response to the pandemic, with 62% satisfied compared to 74% and 73% of faculty and staff, respectively. Further, 77% of faculty think the university's response to continuing education accommodated their needs, compared to 69% of students. Respondents from private universities reported more positive satisfaction than respondents from public universities ($M=4.23$, $SD=0.94$; $t(df=7405)=6.805$, $p<.001$). Qualitative data suggest that older students and faculty needed more technological assistance during this transition to primarily online learning to keep older members involved in the community. Older staff felt that they were more likely to be furloughed and were the group most likely to not have a choice in working on or off campus.

FROM SURVIVING TO EXCELLING: ADAPTATION OF GERONTOLOGY SERVICE LEARNING DURING THE COVID-19 PANDEMIC

Donna Jensen,¹ Theresa Abah,² Carol Sewell,³ and Terrence Ranjo,³ 1. *California State University, Sacramento, Sacramento, California, United States*, 2. *California State University, Sacramento, Sacramento State University,*

California, United States, 3. *Sacramento State University, Sacramento, California, United States*

The COVID-19 pandemic has disproportionately impacted older adults, and the educational service-learning opportunities available to gerontology students. As an applied major, Sacramento State University's Gerontology Department heavily depends on service-learning. The pandemic affected existing gerontology placements and their ability to host student learning. In addition, at the outset of the pandemic, Sacramento State University immediately terminated in-person service learning. The Gerontology Department prioritized student and community safety while still valuing the need for students to have meaningful and relevant community-based learning experiences. Gerontology faculty worked with community partners to shift these vital learning experiences. This poster presentation focuses on the creative ways the department engaged community partners to continue quality learning opportunities for students while assisting community partners with the unrelenting shifts in operations. Three innovative service-learning and community engagement practices will be addressed, including a) Partnering with the California Office of Emergency Services (CalOES) to create and provide the statewide Social Bridging Project for older adults throughout California; b) Expanding the relationship with Sacramento State's Renaissance Society, a lifelong learning and community engagement program for older adults; and c) Partnering with a community-based Cardio-vascular Wellness Program to keep older adults active and engaged while remaining at home. The poster will review the pivot to virtual service learning and share how this shift enhanced student learning and community service. This will include expanding the use of technology and capitalizing on innovative methods to reach out and provide service to older adults, the local community, and the state of California.

LOOKING FOR A BRIGHT SIDE: TALES FROM A RECREATIONAL THERAPY VIRTUAL SERVICE-LEARNING PROJECT DURING A PANDEMIC

Alyssa Doughty,¹ and Jennifer Taylor,² 1. *The Neighbors of Dunn County*, 2. *University of Wisconsin-La Crosse, La Crosse, Wisconsin, United States*

The everchanging policies and inability to utilize university students due to COVID-19 impacted both residents living in long-term care as well as the next generation of students pursuing careers in the field. University Wisconsin-La Crosse (UWL) faculty strategized solutions as restrictions threatened to impact hands-on opportunities for students. Was there a safe and effective solution to offer residents evidence-based programming while also providing students with vital field experience? Simply stated, the answer was yes. Thus, the UWL Happiness Project was born. This session will outline the UWL Happiness Project, a ten-week, telehealth program implemented between a skilled nursing facility in rural Wisconsin and the UWL Therapeutic Recreation Program, an AGHE Program of Merit for Health Professions designated program. The evidence-based curriculum was developed by an emerging UWL graduate student scholar with faculty mentorship. The innovative curriculum focuses on increasing feelings of happiness using PERMA, a theoretical model grounded in positive psychology. During virtual sessions, older adult residents (ages 65-85) and students

built connection while working through weekly focus areas (e.g. vitality, mindfulness, friendship). An overview of AGHE competencies addressed within the project, online course demonstration, and assignment development will be discussed along with information about how these connections fostered an opportunity for students to see aging from a different perspective. This is the first time we are presenting results from the newly developed program. In this, we look forward to sharing student measurements and outcomes, as well as lessons learned during this meaningful, stimulating, and insightful educational session.

TRANSFORMING VIRTUAL TEAM-BASED LEARNING FOR RURAL HEALTHCARE STAFF: WHAT THE PANDEMIC TAUGHT US

Eve Gottesman,¹ Helen Fernandez,² and Judith Howe,³

1. *US Department of Veterans Affairs, Bronx, New York, United States*, 2. *Icahn School of Medicine at Mount Sinai, New York, New York, United States*, 3. *James J. Peters VA Medical Center, Bronx, New York, United States*

During COVID-19, many training programs pivoted to virtual formats. For the Rural Interdisciplinary Team Training (RITT) Program, funded by the Veterans Health Administration as part of the Geriatric Scholars Program, there were unique challenges. Given a history of successful accredited in-person, team-based workshops for staff at rural and remote clinics, program developers needed to quickly devise a plan for an effective virtual training for team members working separately from each other. Without the ability to provide in-person education and training, rapid pivoting to virtual modalities was essential for ongoing education of those providing care for older adults. Using a web-based platform, team members and expert trainer facilitation, participants engaged in lively discussions and reflection using the chat feature. RITT adapted the curriculum to better meet the needs of busy healthcare providers working during the pandemic, including increased discussion of how COVID affects older Veterans. Three virtual RITT workshops were held between March 2020 and February 2021 with 64 participants from 12 rural clinics and medical centers. Over 90% of participants agreed or strongly agreed that they were satisfied with the virtual workshop, comparable to those participating in the in-person workshop in earlier years. Similar to others, we have found that the ability to flex a curriculum has benefits to both learners and educators and increases the reach of educational opportunities in gerontology and geriatrics. Particularly in rural areas where travel may be challenging, a virtual format may be a desirable long-term solution for the RITT program.

Session 9175 (Poster)

COVID-19, Health Services, Behaviors, and Outcomes

CHANGES IN WELL-BEING DURING THE COVID PANDEMIC: A LONGITUDINAL STUDY OF OLDER ADULTS

Andrea Huseth-Zosel,¹ and Heather Fuller,² 1. *North Dakota State University, Fargo, North Dakota, United*

States, 2. *North Dakota State university, Fargo, North Dakota, United States*

The COVID-19 pandemic is a public health crisis the world has not seen in a century, with older adults faced with unique impacts due to their increased vulnerability and need to social distance. This research examines changes in physical and mental health and quality of life among older adults in the upper Midwest during the COVID-19 pandemic. Seventy older adults aged 70-97 participated in three phone interviews (April [Time 1], June [Time 2], and October [Time 3] 2020) focusing on experiences coping with the pandemic and understanding overall changes in well-being. Participants rated their quality of life, physical health, and mental health on a scale from 1 to 5 with 1 being "Poor" and 5 being "Excellent." Self-reported quality of life, mental health, and physical health initially declined between retrospective pre-COVID and Time 1 scores, with gradual increases seen across all three variables for Time 2 and Time 3 scores. Thematic analysis of qualitative responses for each interview wave identified salient themes of: 1) reduced quality of life, 2) distraction and routine, 3) loss and uncertainty, and 4) resilience and adaptation. The significance and meaning of these themes shifted across each time point. For example, the reduced quality of life theme initially encompassed loss of activities, later shifted to concerns about struggles to maintain relationships, and finally focused on hope for the future. Findings will be discussed in light of the significance of change over time as well as policy and practice implications for older adults.

COVID-19 PANDEMIC ON SMOKING BEHAVIOR CHANGES AMONG AFRICAN AMERICAN SMOKERS ELIGIBLE FOR LDCT SCREENING

Tung-Sung Tseng,¹ Yu Hsiang Kao,² and Mirandy Li,¹ 1. *LSUHSC, New Orleans, Louisiana, United States*, 2. *LSUHSc, New Orleans, Louisiana, United States*

Smoking has been observed to associate with an elevated severity of disease and risk of mortality among people with COVID-19. Additionally, African American smokers have higher rates of mortality from lung cancer than other racial/ethnic groups. Low dose computed tomography (LDCT) screening can detect lung cancer early to decrease lung cancer-specific mortality for current smokers but remains under-utilized among these population. However, we know little about the effect of COVID-19 pandemic on smoking behavior changes among African American smokers who qualify for LDCT screening. This study recruited 60 African American daily smokers seen in primary care clinics, who qualified to receive LDCT screening in a New Orleans, LA hospital. A total of 22 participants (36.7%) completed anonymous cross-sectional survey that collected demographic, disease history, tobacco use, and smoking cessation behaviors during the period of COVID-19 pandemic via phone interview. The majority were older (61.2 [SD=4.7]), female (77.3%), earned annual income less than \$20,000 (100.0%), had Medicaid (63.6%), overweight/obesity (72.7%), planned to quit smoking within 6 months (52.4%), and would consider taking LDCT screening after COVID-19 pandemic (95.2%). Half of smokers reported they have been diagnosed hypertension (47.6%), diabetes (52.4%), and arthritis (57.1%). Regarding health behavior changes,

42.9% smokers reported they smoked more, felt more stress (42.9%) and anxiety (33.4%) after COVID-19 outbreak. Smoking cessation programs may focus on this high-risk minority population in the post COVID-19 pandemic to help them decrease cigarette smoking and enhance their motivation to quit smoking.

HEALTH BEHAVIORS IN TIMES OF COVID: DIFFERENT SOURCES OF SUPPORT FOR OLDER ADULTS

Elizabeth Zambrano Garza,¹ Theresa Pauly,² Rachel Murphy,¹ Wolfgang Linden,¹ Maureen Ashe,³ Denis Gerstorff,⁴ Kenneth Madden,¹ and Christiane Hoppmann,³ 1. *University of British Columbia, Vancouver, British Columbia, Canada*, 2. *University of Zurich, University of Zurich, Zurich, Switzerland*, 3. *University of British Columbia, University of British Columbia, British Columbia, Canada*, 4. *Humboldt University of Berlin, Humboldt University of Berlin, Brandenburg, Germany*,

Eating a nutritious diet reduces vulnerability to common chronic diseases. Yet, older adults struggle to meet nutritional guidelines; many have found it particularly challenging to access fresh foods such as fruits and vegetables during the pandemic. Thus, it is vital to better understand how older adults may recruit the help of close others to support healthy dietary intake. This COVID-19 study examines the role of support for promoting fruit and vegetable consumption in daily life. Ninety-seven older adults participated with a close other of their choice (62 % spouse; 38% non-spouse Mage partner1 = 72, SD = 5.26, Mage partner2 = 62, SD = 16.38). Both partners completed two daily questionnaires for 10 days. In the morning they reported their intentions for eating fruit and vegetables. In the evening, they noted their consumed fruit and vegetable servings, the extent to which this matched their intentions, and their partners support in doing so. Consistent with previous research, the older participants were, the more they consumed fruits and vegetables. On days when participants received more support from their partner, they were more successful at reaching their dietary goals. Interestingly, initial findings suggest that associations were stronger when support was provided from a non-spouse than if the support came from spouse. Follow-up analyses, with a larger sample, will further examine some of the underlying mechanisms so as to better understand the role of different kinds of support providers during the pandemic and shed light on who may be best suited to provide support.

HEALTH IMPACTS OF THE COVID-19 PANDEMIC AMONG OLDER ADULTS WITH CHRONIC CONDITIONS

Courtney Polenick,¹ Vanessa Lee,² Shreya Salwi,² Nikita Daniel,² Annie Zhou,² Summer Meyers,² and Diarratou Kaba,² 1. *University of Michigan, Ann Arbor, Michigan, United States*, 2. *University of Michigan, University of Michigan, Michigan, United States*

The COVID-19 pandemic may have adverse health implications, particularly among older adults with chronic conditions who are at increased risk of severe illness. This cross-sectional study examined the early health impacts of the pandemic among adults aged 50 and older with chronic conditions. Participants included 700 adults (M = 64.60 years,

SD = 8.85, range = 50 – 94) from Michigan (82.4%) and 33 other U.S. states who reported at least one chronic condition and completed an anonymous online survey between May 14 and July 9, 2020. Of these, 488 also provided open-ended responses. Individuals reported lower illness self-efficacy, less consumption of fruits, vegetables, and fried foods, and lower physical activity, along with greater alcohol use since the pandemic. About half (42.7%) reported worsened sleep. One in five (20.1%) reported at least some difficulty obtaining medications and over half (60.4%) reported at least some difficulty receiving routine care. Almost two-thirds (63.9%) had delayed preventative care and one in five (19.3%) had delayed essential medical treatment. Nearly half (42.6%) avoided contacting care providers about a physical health concern and one in eight (12.9%) avoided reporting mental health concerns. Qualitative data revealed that the pandemic has influenced how participants cared for their physical health through following guidelines related to COVID-19; coping with daily routine changes; greater awareness of self-care; mental health impacts; and health care disruptions. Older adults with chronic conditions report distinct pandemic-related challenges for self-care and health care that should be addressed in interventions to maintain their health and functioning.

MEMORY PROBLEMS DURING COVID IN LOW- INCOME OLDER ADULTS

Faika Zanjani, and Annie Rhodes, *Virginia Commonwealth University, Richmond, Virginia, United States*

Prevention, with widespread lifestyle risk reduction at the community-level, is currently considered an effective method to decrease Alzheimer's disease (AD). As part of the Virginia Commonwealth University iCubed Health and Wellness in Aging Core, diverse older adults (60+) living in Richmond, VA, with incomes below \$12,000/year and managing either diabetes/cardiovascular symptoms, were offered weekly lifestyle telephone-health coaching for 12-weeks, providing education, motivations, self-efficacy, and referral services for AD lifestyle risk. The study sample (n=40, mean age 68 years (range: 60-77 years) was 88% African American/Black (n=35), 100% Non-Hispanic, and 45% males (n=18)). Thirty-nine (95%) of subjects successfully participated in coaching sessions; on average 91.9% (11) sessions/subject were completed. Participants provided positive anecdotal feedback and the need for continued health coaching during COVID. N=30 (75%) of the original sample consented for continued health coaching during the Covid pandemic, 63% female, 88% African American/Black, 60-77 age range (mean age 69 years), and 47% reporting memory problems. Baseline Covid interviews indicated poorer health status associated with reporting memory problems for poor physical health days (F=7.03;p=.01); poor mental health days (F=6.88;p=.01); total mental/physical health poor days (F=2.76;p=.11); sad days (F=15.52;p=.001); worried days (F=6.27;p=.02); tired days (F=9.77;p=.004); feelings of emptiness (F=10.09;p=.004); feelings of rejection (F=3.382;p=.08); feelings of failure (F=7.58;p=.01); little interest/pleasure (F=7.84;p=.009); and feeling down (F=6.75;p=.02). In conclusion, this preliminary work creates the impetus for future large-scale AD prevention investigations to improve the lives of AD-risk, low-income, diverse older adults reporting

memory problems. This research indicates the subjective reporting of memory problems requires health intervention.

TALKING THROUGH TECHNOLOGY: MAINTAINING ESSENTIAL CONTACTS WITH OLDER ADULTS DURING THE COVID-19 PANDEMIC

Marcia Shade,¹ Sarah Hubner,² Julie Blaskewicz Boron,² Stephen Kotopka,¹ and Natalie Manley,¹ 1. *University of Nebraska Medical Center, Omaha, Nebraska, United States*, 2. *University of Nebraska Omaha, Omaha, Nebraska, United States*

Older adults are at increased risk for contracting COVID-19 and are more vulnerable to poor outcomes. Public health efforts to prevent spread of COVID-19 resulted in widespread social/physical distancing; this changed adults' regular communication with their essential contacts, warranting development of solutions for socialization to reduce loneliness, bolstering quality of life. Essential contacts provide social/emotional/physical care for community-dwelling or institutionalized adults. This study aimed to explore how essential contacts of older adults utilize technology to maintain social connection in response to COVID-19. Participants (N=156) aged 55+ completed a Qualtrics questionnaire via Amazon Mechanical Turk; demographic, social contact, and technology use data were collected. Respondents (M Age=62.2±4.9) were generally female (72.4%), white (89.7%), and a contact for an institutionalized adult (59%). Data were analyzed descriptively with binary regressions. Results revealed that volumes of general [X²(4, N=156)=37.69, p<.001], in-person [X²(4, N=156)=37.84, p<.001], and distanced [X²(4, N=156)=27.69, p<.001] social interaction were significantly associated with the older adult's environment (community-dwelling vs. institutionalized). In-person conversation was significantly associated with environment [X²(1, N=156)=29.38, p=0.001], while other technology-based communications (e.g., video-chat) were not. In-person conversation was positively predicted by the contact being a physical caregiver (B=2.324, p<.001), while smartphone use was positively predicted by being a social contact (B=1.287, p<.05). Findings suggest that although technology was used by participants to communicate with their older adult contacts across groups, environment and caregiver/contact type significantly influenced communication. It may be that, throughout COVID-19, dyads have relied on familiar methods of socialization, or that there is lack of access to more sophisticated technologies for communication. This warrants future investigation.

TECHNOLOGY USE AMONG OLDER ADULTS TO MANAGE THEIR HEALTH DURING A GLOBAL PANDEMIC

Gashaye M. Tefera, Erin Robinson, and Geunhye Park, *University of Missouri, Columbia, Missouri, United States*

Risk of severe COVID-19 illness increases with age, and older adults are more likely to be hospitalized and die from COVID-19 and related complications as compared to their younger counterparts. This reality, combined with pandemic-related lockdown and social distancing policies, has increased in-home isolation for older adults. This includes cancelling in-person healthcare appointments and conducting many appointments via tele-health. As older

adults have had to quickly pivot to learning new technologies, little is known about their experiences with navigating virtual healthcare during the pandemic. Therefore, this qualitative study aims to address that gap. One-on-one interviews (N=29) were conducted with older adults (Mean age=71.5; 86% female) via phone/Zoom. Participants were asked about their healthcare experiences during the pandemic and the role technology played. Interviews were transcribed and thematically analyzed using Nvivo12 software. Findings demonstrate that participants used technology to schedule medical appointments, engage in virtual visits with their providers, set reminders to take medications, and undertake their daily exercise routine. Post-lockdown, some participants preferred in-person visits due to the nature of their diagnosis, personal preference, or unfamiliarity with the needed technology. Older adults encountered challenges including cancelled appointments, miscommunication with providers, and lack of skill to use technologies. Cancellation of appointments and postponement of treatments affected the health of some of the participants. Implications of this research can inform tele-health approaches with older patients, as well as provider communication and coordination of care. Leveraging technology for preventative health approaches can also assist older adults in ongoing health maintenance and promote well-being.

TELEHEALTH AS AN ELEMENT OF HOME AND COMMUNITY-BASED SERVICES IN A PANDEMIC: AN INTRINSIC CASE STUDY IN TWO RURAL AREAS

Nancy Karlin,¹ and Joyce Weil,² 1. *University of Northern Colorado, Greeley, Colorado, United States*, 2. *University of Northern Colorado, University of Northern Colorado, Colorado, United States*

COVID-19 has changed the face of health care delivery. Using technology as a way to ensure Home and Community-Based Services (HCBS) as an option for older adults in rural areas is of increasing interest as a result of the pandemic. Literature suggests older adults do not adopt telehealth and/or medicine practices due to barriers (e.g., Internet and computer availability) and do not use telemedicine as a form of communication with medical staff. However, the combination of needing health care during the pandemic and having federal coverage via Medicare for telehealth virtual visit. Still studies suggest older adults may lack the necessary information about how to adopt telehealth and telemedicine and that they do not see their benefits. Additionally, the cost of technology, limited Internet access and rural connectivity issues persist. This study evaluates the potential for telehealth/medicine use in rural communities through two case studies of rural older persons in the Eastern Plains of Colorado and rural Western Nebraska. Results indicate, for older persons responding to the telehealth/medicine questions, there is support for its potential use with some using teleconferencing, health portals, along with the expectation that telehealth/medicine would be part of new health care systems. Resistance was met by some older adults in the Colorado sample who preferred face-to-face contact alongside other concerns about potential usage barriers such as the lack of Internet services or consistent connectivity. These participants indicated a lack of awareness in finding out how to access this form of medical support.

THE IMPACT OF COVID-19 ON OLDER ADULTS

Rachel Ungar,¹ Rifky Tkatch,² Jane Huang,¹ Sandra Kraemer,³ James Schaeffer,¹ and Charlotte Yeh,⁴
 1. *UnitedHealth Group, Minnetonka, Minnesota, United States*, 2. *UnitedHealth Group, Oak Park, Michigan, United States*, 3. *UnitedHealthcare, Minnetonka, Minnesota, United States*, 4. *AARP Services, Inc., Washington, District of Columbia, United States*

Background: The onset of the COVID-19 pandemic has dramatically influenced the health and well-being of older adults. Changes in lifestyle patterns has required reframing communication habits and learning new skills to maintain social connections and access healthcare. **Objectives:** To assess 1) well-being measured prior to and during the COVID-19 era; and 2) use and comfort level of technology for social interactions and telehealth visits during this time. **Methods:** A mailed survey to a randomly selected national sample (>65) during the summers of 2018, 2019, and 2020. Measures included mental and physical well-being and various psychosocial measures. For 2020, questions related to COVID-19 and the use of technology were included. **Results:** A total of 4,696 (2018), 3,976 (2019) and 2,726 (2020) responded to these surveys (response rate ~27%). Overall, most constructs remained stable despite the ongoing pandemic. Most respondents reported average or high resilience (90%), high purpose (48%), stable social networks (76%), and low stress (55%). However, loneliness increased during 2020 (57%). Respondents who used technology were more likely to connect with family and friends. Only 43% reported high comfort with using technology, with older age (>75) less comfortable. At the time of the survey 37% had not seen a healthcare provider through telehealth services, and 15% felt their healthcare needs were not met by a telehealth experience. **Conclusion:** Results demonstrate that respondents were doing well during COVID-19. Yet increases in loneliness and greater technology needs to stay socially connected and to access healthcare may result in negative long-term health outcomes.

Session 9180 (Poster)

COVID-19, Social Support, Social Connectedness, and Loneliness

AGING, EMPATHY, AND PROSOCIAL BEHAVIORS DURING THE COVID-19 PANDEMIC

Isu Cho,¹ Ryan Daley,² Tony Cunningham,² Elizabeth Kensinger,² and Angela Gutches,¹ 1. *Brandeis University, Waltham, Massachusetts, United States*, 2. *Boston College, Chestnut Hill, Massachusetts, United States*

Previous literature has shown age-related increases in prosociality (i.e., the tendency to engage in behaviors that benefit others). Can such age-related differences be observed during the COVID-19 pandemic, or would young adults' higher levels of COVID-19-related stress alter the relation between age and prosociality given the prior findings that stress may promote prosocial behaviors? Can empathy, one of the factors highly related to prosociality, explain any observed age-related differences? The current study examined the above questions, as well as whether age differences exist

in target of prosocial behaviors (i.e., distant- versus close-others). To this end, participants (aged 18-89) enrolled in an ongoing study examining their experiences during the COVID-19 pandemic. They were asked to complete a series of surveys on dispositional empathy and prosocial behaviors during the pandemic. In the present analyses, the data were used from 330 participants from the USA who completed all of the surveys. Compared to younger adults, results indicate that older adults showed greater prosocial behaviors during the pandemic despite their higher risk of physical-health complications from COVID-19. Unexpectedly, empathy did not explain such age-related increases in prosocial behaviors even though it was positively related to individuals' prosociality. Interestingly, older adults reported increased prosocial behaviors towards close-others (i.e., family, friends) compared to young adults, suggesting that older adults seem to devote more resources into emotionally meaningful relationships. The current study contributes to our understanding of how prosociality differs with age during the stressful period of need that marks the COVID-19 pandemic.

COVID-19 CONCERNS, DEPRESSION AND LONELINESS IN MIDDLE-AGE AND OLDER ADULTS

Angela Curl, and Katie Wolf, *Miami University, Oxford, Ohio, United States*

The coronavirus pandemic forced many people to restrict their activities and social interactions out of fear and due to local health regulations. This study examined whether one's self-reported level of concern related to COVID-19 was associated with loneliness and depressive symptoms. Using early release 2020 data from the Health and Retirement Study (N=2,759 adults over age 50), we conducted ordinary least-squares and logistic regressions, controlling for age, gender, education, marital status, self-rated health, and exercise. Higher levels of self-reported concern about the coronavirus pandemic were associated with more depressive symptoms ($B=.05$, $p<.01$) and increased odds of being lonely ($OR=1.05$, $p<.01$). Female sex, lower education, not being married, worse self-rated health, and lack of exercise were associated with more depressive symptoms and higher odds of being lonely, while older age was associated with lower depression but higher odds of loneliness. These results suggest that mental health assessments should include measures specifically asking about COVID-19 concerns and experiences (e.g., COVID-19 diagnosis, death of close friends or family due to COVID-19, unable to attend important events). The pandemic has raised public awareness of the negative consequences of social isolation and acted to destigmatize mental illness, and this could encourage middle-aged and older adults to seek professional help for depression.

LONELINESS AND NEUROPSYCHIATRIC SYMPTOMS IN COGNITIVELY IMPAIRED OLDER ADULTS DURING COVID-19 PANDEMIC

Prasad Padala,¹ Ashlyn Jendro,¹ Clinton Gauss,¹ Kerrie Wilson,¹ Aparna Das,² Samuel House,¹ Scott Mooney,¹ and Kalpana Padala,³ 1. *Central Arkansas Veterans Healthcare System, North Little Rock, Arkansas, United States*, 2. *University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*, 3. *Central Arkansas Veterans Healthcare System, Central Arkansas*

Veterans Healthcare System, North Little Rock, Arkansas, United States

Background: Cognitively impaired older adults living in the community have been vulnerable to the effects of COVID-19 confinement. The current study's objectives were to examine the prevalence of loneliness in such adults along with impact of COVID-19 on neuropsychiatric symptoms and functional status. **Methods:** A cross-sectional study was conducted in community dwelling cognitively impaired older Veterans (N=41). Demographic data such as age, gender, race, and rurality were collected. Loneliness data were collected with the 3-item Loneliness Questionnaire. Cognition was assessed with the Tele-Montreal Cognitive Assessment (T-MoCA) and functional status of instrumental activities of daily living was assessed with the Functional Activities Questionnaire (FAQ). Neuropsychiatry symptoms including severity and distress were collected using the Neuropsychiatric Inventory (NPI), and change during COVID was also recorded for each symptom. **Results:** Demographic characteristics included: mean age of 71.9 (± 8.6) years, 95.1% male, 46.3% rural, 75.6% Caucasian, and 19.5% African American. Loneliness was prevalent in most participants (62.5%). T-MoCA and FAQ mean scores were 15.1 (± 4.5) and 10.0 (± 8.6), respectively. Mean NPI total severity and total distress were 8.4 (± 5.9) and 11.4 (± 8.5), respectively. Irritability was most frequently reported symptom (65%), followed by agitation (57.5%), anxiety (55%), depression (50%), and night-time behavior (50%). A majority of the participants reported worsening of neuropsychiatric symptoms during COVID (71.1%). Among those that reported worsening neuropsychiatric symptoms, 70.4% noted an increase in ≥ 2 symptoms. **Conclusion:** Older adults with pre-existent cognitive impairment may be at high risk for loneliness and worsening of neuropsychiatric symptoms during the COVID pandemic.

LONELINESS BEFORE AND DURING THE COVID-19 PANDEMIC: ASSOCIATIONS WITH CHRONIC ILLNESSES AND RELATIONSHIP QUALITY

Jay Kayser,¹ and Jacqui Smith,² 1. *University of Michigan, Ann Arbor, Michigan, United States*, 2. *University of Michigan, University of Michigan, Michigan, United States*

While self-reported loneliness generally declines after age 65, the likelihood of experiencing chronic illnesses increases. During the Covid-19 pandemic, social isolation measures have changed the social context of many people. We address three research questions: 1) What is the predictive strength of chronic illnesses, relationship quality, and their interaction on loneliness? 2) Has Covid-19 altered experienced loneliness relative to pre-pandemic? 3) Was loneliness during Covid-19 associated with the number of prior chronic illnesses in 2016? To answer these questions, we have analyzed data from participants in the Health and Retirement Study (HRS) included in the early 2020 release who also completed the 2016 wave (N = 1106). On average, in 2016, these participants were age 74.64 (SD = 6.66) and reported 2.57 (SD = 1.39) chronic illnesses. In 2016, unadjusted multiple regression models revealed that chronic illnesses ($\beta = .38$) and relationship quality ($\beta = -.41$) were associated with loneliness ($R^2 = .28$). When covariates were added, these values were attenuated but remained statistically significant. In 2020 during the pandemic, 8% of these participants reported they often felt lonely and

26% reported feeling lonelier since the start of the Covid-19 pandemic. People who had more chronic illnesses in 2016 reported feeling lonelier in 2020 as did people whose relationships were poorer quality ($p < .05$). Further analyses with final data from HRS are needed to confirm these trends. These findings highlight the importance of having longitudinal information to identify individuals at high risk and most likely to benefit from interventions.

LONELINESS DURING COVID-19 AND MODES OF SOCIAL CONTACT USE AMONG OLDER ADULTS

Usha Dhakal, and Athena Koumoutzis, *Miami University, Oxford, Ohio, United States*

Due to social distancing and isolation recommendations, COVID-19 resulted in older adults' greater reliance on technology to contact friends and families. While the mental health of older adults during COVID-19 has been well explored, less is known about how changes in modes and frequency of social contact is associated with loneliness. Using the National Health and Aging Trends Study COVID-19 data, this study assessed how the frequency of varying modes of contact (e.g., phone/email/text, in-person visits, videocalls) during the pandemic was associated with feelings of loneliness during COVID-19 among community-dwelling Medicare beneficiaries (n = 2149). Participants were asked if they felt lonely "more often," "less often," or "about the same" compared to before the outbreak started. Multinomial regression analyses indicated that, compared to those who reported daily in-person visits, the odds of having more feelings of loneliness as compared to about the same as pre-COVID-19 was significantly higher among those who reported having in-person visits a few times (OR=2.17, CI=1.08-4.36), at least once (OR=2.37, CI=1.11-5.04), and never/less than once a week (OR=3.37, CI=1.59-7.16) while controlling for demographics, household, and social network size. Compared to daily use, use of phone/email/text at least once (OR=0.44, CI=0.201-0.965) or a few times (OR=0.76, CI=0.58-0.99) a week was associated with lower odds of reporting more feelings of loneliness versus about the same. Results suggest that greater use of technology that promote social engagement improves social connectedness and decreases COVID-19 related loneliness among older adults, and highlights the importance of older adults' access to technology, including reliable internet.

OLDER ADULTS' WORRY ABOUT COVID-19: ASSOCIATIONS WITH EXPERIENCES OF COVID-19 AMONG SOCIAL CONNECTIONS

Amanda Leggett,¹ Hyun Jung Koo,² Lindsay Kobayashi,² Jessica Finlay,² Hannah Lee,² and Elaina Baker,² 1. *The University of Michigan, Ypsilanti, Michigan, United States*, 2. *University of Michigan, Ann Arbor, Michigan, United States*

The COVID-19 pandemic has challenged the physical and mental health of older adults, yet it is unknown how much older adults worry about their own exposure. As older adults are at increased risk for severe complications from COVID-19, understanding patterns of worry may inform public health guidelines and interventions for this age group. We investigated older adults' worry about COVID-19 in the early months of the pandemic and associations with familial/

friend's diagnosis or disease symptoms. Data comes from the baseline (April/May 2020), one-month, and two-month follow-up surveys from the COVID-19 Coping Study, a national longitudinal cohort study of US adults aged ≥ 55 . We used linear regression models to investigate the association between self-reported familial/friend diagnosis or symptoms with pandemic worry, accounting for demographic factors and individual diagnosis or experience of COVID-19 symptoms. Participants (Baseline=4379, 1 month= 2553, 2 month=2682) were 67 years old on average, 72% were female, 5.7% were non-White, and 80.5% had a college degree. At baseline, 26.6% of participants had friends or family who had been diagnosed or experienced symptoms of COVID-19. Having friends or family diagnosed or with symptoms of COVID-19 ($B=0.08$, $SE=0.04$, $p<.05$), being female ($B=0.42$, $SE=0.03$, $p<.001$), and having higher educational attainment ($B=0.06$, $SE=0.02$, $p<.001$) were significantly associated with greater worry about COVID-19. These associations were consistent over 3 months. Understanding if worry about the pandemic correlates with following public health guidelines is a key next step so intervention strategies can prioritize older adults and their social networks.

PREVALENCE OF SOCIAL ISOLATION BEFORE AND DURING THE COVID-19 PANDEMIC: A NATIONWIDE WEB-BASED SURVEY IN JAPAN

Hiroshi Murayama,¹ Ryo Okubo,² and Takahiro Tabuchi,³
 1. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan*, 2. *National Center of Neurology and Psychiatry, Kodaira, Tokyo, Japan*, 3. *Osaka International Cancer Institute, Osaka, Osaka, Japan*

The coronavirus disease 2019 (COVID-19) pandemic is assumed to have increased the number of socially isolated older adults. Public health researchers and policymakers are concerned about the deleterious effects of social isolation on individuals' health. However, there is only limited evidence on the prevalence of social isolation. This study investigated the change in prevalence of social isolation caused by the spread of COVID-19 and examined various associated factors. Accordingly, data from the JACSIS study, a nationwide cross-sectional web-based questionnaire survey ($N=28,000$, age: 15–79 years) conducted in August–September 2020 (during the pandemic) were analyzed. The respondents who contacted family members, friends, or neighbors less than once a week were considered socially isolated. We examined individuals' frequencies of contact, including meeting in person, e-mail/text message, voice call, and video call, in January (before the pandemic; recall question) and August 2020. The weighted prevalence values of social isolation were 26.8% (26.0%–27.5%) in men and 15.8% (15.1%–16.4%) in women before the pandemic and increased to 34.4% (33.6%–35.2%) and 21.4% (20.7%–22.1%), respectively, during the pandemic. Further, compared to the younger age group, the increase in prevalence during the pandemic was greater for the older age group for both genders. Multinomial logistic regression analysis revealed that those who came to be socially isolated during the pandemic possessed a greater fear of COVID-19 than those who were not continuously socially isolated. These findings suggest the necessity of developing immediate measures for social isolation and risk communication regarding COVID-19.

SOCIAL ISOLATION IN OLDER WOMEN DURING THE COVID-19 PANDEMIC: THE IMPACT ON QUALITY OF LIFE AND MENTAL HEALTH

Victoria Marshall,¹ Robina Sandhu,² Kathryn Kanzler,³ Sara Espinoza,¹ Pamela Keel,⁴ Andrea LaCroix,⁵ Nicolas Musi,³ and Lisa Kilpela,³
 1. *University of Texas Health Science Center San Antonio, San Antonio, Texas, United States*, 2. *University of Texas Health Science Center, San Antonio, Texas, United States*, 3. *UT Health San Antonio, San Antonio, Texas, United States*, 4. *Florida State University, Tallahassee, Florida, United States*, 5. *University of California at San Diego, San Diego, California, United States*

To mitigate the spread of COVID-19, countries worldwide enacted quarantines, particularly for older adults, as mortality from COVID-19 is inequitably distributed among this group. Notably, social isolation in older adults is associated with a heightened risk of cardiovascular, autoimmune, and mental health problems (e.g., depression, anxiety). Furthermore, the mental health of women in particular has been greatly impacted by the pandemic. Although previous research indicates that social isolation among older adults is a "serious public health concern", less is known about the extent to which the COVID-19 pandemic has exacerbated this issue. The primary objective is to investigate the effects of social isolation on mental health indices and health-related quality of life (HRQOL) in older women in the context of the COVID-19 pandemic. Participants include 77 postmenopausal women (aged 60+) who completed self-report measures online during the COVID-19 pandemic. Controlling for education and annual household income in all analyses, we used linear regression models to investigate the effects of social isolation on depression, anxiety, alcohol use, binge eating, and the 8 domains of the SF-36. Results indicate that, when controlling for education and income, social isolation significantly predicted depression, binge eating, and poorer HRQOL in all 8 domains of the SF-36 (all $p's < .01$). Social isolation did not predict anxiety and alcohol consumption when controlling for these sociodemographic variables. Enrollment is ongoing; this poster will report updated results. Results indicate the continued need for creative avenues to improve social connectedness during the COVID-19 pandemic.

SOCIAL SUPPORT IS ASSOCIATED WITH BETTER HEALTH IN THE FACE OF COVID-19

Laura Bernstein, and Julie Hicks Patrick, *West Virginia University, Morgantown, West Virginia, United States*

The COVID-19 pandemic has the potential to influence the health of the nation, both directly and indirectly, though increased stress. As with other stressful crises, social support may buffer against the deleterious effects of the stress surrounding COVID-19 (Cohen & Wills, 1985). We were interested in how self-reported health changed during the first year of the COVID-19 pandemic in the United States and whether age or positive social exchanges influenced this potential change. We tested a latent growth curve model of change in SF12 scores over 4 points of measurement during the first year of the pandemic. Data from 237 adults (Mean age 40.7 yrs) were used to test whether SF12 scores changed over the 11 month period and whether age and initial positive social exchanges influenced both the intercept and trajectory

of change over time. Results showed that the model fit the data well, X^2 (DF = 13, N = 237) = 11.44, $p = .57$, RMSEA < .06. Of note, older age was associated with both better initial health ($b = .036^{**}$) and a slower decrease over the year ($b = -.005^*$). Initial positive social exchanges were associated with better initial health ($b = .067^*$) but did not alter the trajectory of change over time. These findings suggest an age-related advantage for health in the face of COVID-19 and that positive social support is associated with better health, at least at the very beginning of the pandemic.

VET TO VET MAINE: COVID 19 EFFECT ON A VETERAN COMPANION PILOT STUDY IN REDUCING SOCIAL ISOLATION AND LONELINESS

Marilyn Gugliucci,¹ Amy Lin,² and Shirley Weaver,³

1. *University of New England College of Osteopathic Medicine, Kennebunk, Maine, United States*, 2. *University of New England, University of New England, Maine, United States*, 3. *University of New England College, University of New England, Maine, United States*

Background: Maine veterans represent 11.8% of Maine population, twice that of the United States. Veterans are at risk for social isolation, loneliness and suicide. The mission of Vet To Vet (V2V) Maine, a non-profit organization, connects trained veteran volunteers with fellow veterans (veteran friends) for companionship, assistance with benefits, and support independent living. This study: (1) assessed if V2V program fulfilled its mission; and (2) determined any care partner effects from the program. Methods: Mixed methods research spanned 6-months, 2019-2020. Twenty-four participants; trained Veteran Volunteers (VV) were paired with Veteran Friends. Four Care Partners (CP) of Veteran Friends participated. Assessments included pre/post Veteran Rand Health Survey (VR-12), Patient Health Questionnaire (PHQ-9), and Late Onset Stress Symptomatology (LOSS) Short Form. CPs completed pre/post Zarit Burden Interview (ZBI-22) assessments. Qualitative interviews focused on visits/activities, relationship building, and program feedback. Data analyses included Wilcoxon Sign Test and NVivo 12+ Qualitative Data Analysis Software. Results: Pre/post data failed to show significance ($P=.05$), however trends supported an improvement in mental and physical health scores. COVID-19 was a confounding variable as state stay-at-home orders occurred at the companion program study mid-point. Three key themes included; (1) Veteran Companionship; (2) Effects of COVID; and (3) Care Partners. The V2V Companion program was determined effective and reported highly successful relationship matches. CPs confirmed the importance and benefits of V2V. Conclusion: The V2V Maine companion program pilot research supported success in connecting Veterans Volunteer and Veteran Friends; fostering companionship, friendships, mentoring, assisting with benefits, and supporting independent living.

VILLANOVA REACHOUT FORMING CONNECTIONS WITH OLDER ADULTS

Christina Whitehouse,¹ Catherine Curley,² Caitlin Gomes,² Michelle McKay,² Christine Brewer,² and Melissa O'Connor,³
1. *Villanova University, Villanova University, Pennsylvania, United States*, 2. *Villanova University, Villanova University, Pennsylvania, United States*, 3. *Villanova University,*

M. Louise Fitzpatrick College of Nursing, Villanova, Pennsylvania, United States

Older adults are at increased risk for loneliness and social isolation. Research on loneliness identifies increased rates of depression, increased cognitive decline, and poor cardiovascular health outcomes. The COVID-19 pandemic forced many older adults into social isolation for protection against this insidious virus. Mandated lockdowns and personal decisions to shelter-in-place produced a tremendous increase in rates of loneliness, especially among older adults. Identifying a need for communication and relationships, we created Villanova ReachOut, a program that partners interprofessional students (N= 66) with older adults (N=53) through weekly telephone or video calls. To assess the impact of our program we developed a five question survey administered via phone to older adults and a 13-item survey for volunteers to assess training, satisfaction, needs and impact of the program. Of the older adults (n=16) who completed the survey, 78.6% believe the program helped them feel less isolated throughout the pandemic and 93.8% indicated they looked forward to weekly calls with their partner. Volunteers who completed the survey (N=25), overwhelmingly stated they enjoy and look forward to their calls (100%) and their communication skills have improved (92%). Volunteers reported being paired up with an older adult for weekly conversation had a positive impact on their personal and professional development. Findings from our program evaluation provide rich data in descriptions of positive impact for both the older adult and volunteer. These findings also support the need for programs that engage in intergenerational dialogue, specifically targeting older adults and the potential older adult workforce.

Session 9185 (Poster)

Dementia and Quality of Life

ALZHEIMER'S PREVENTION LIFESTYLE RISK COACHING IN LOW-INCOME OLDER ADULTS

Faika Zanjani, and Annie Rhodes, *Virginia Commonwealth University, Richmond, Virginia, United States*

Prevention, with widespread lifestyle risk reduction at the community-level, is currently considered an effective method to decrease Alzheimer's disease (AD). As part of the Virginia Commonwealth University iCubed Health and Wellness in Aging Core, diverse older adults (60+) living in Richmond, VA, with incomes below \$12,000/year and managing either diabetes/cardiovascular symptoms, were offered weekly lifestyle telephone-health coaching for 12-weeks, providing education, motivations, self-efficacy, and referral services for AD lifestyle risk. The study sample (n=40, mean age 68 years (range: 60-77 years) was 88% African American/Black (n=35), 100% Non-Hispanic, and 45% males (n=18)). Thirty-nine (95%) of subjects successfully participated in coaching sessions; on average 91.9% (11) sessions/subject were completed. On a scale of 0-100 (higher scores more positivity), rated their experience 93.3. On a scale of 0-10 (higher scores more improvement), rated their health improved 8.36. Pre/post-test analyses indicated lifestyle improvement trends over 4-months for total lifestyle risk ($F=4.69$; $p=.037$; $effect=.12$),

social activity ($F=4.63$; $p=.063$; $effect=.09$), and improvement in certain psychological domains: AD knowledge ($F=4.49$; $p=.041$; $effect=.11$); cognitive functioning (short-term memory ($F=4.99$; $p=.038$; $effect=.21$); delayed memory ($F=2.26$; $p=.154$; $effect=.11$); Trails A ($F=5.60$; $p=.0294$; $effect=.24$); and Trails B ($F=2.22$; $p=.154$; $effect=.11$). Participants provided positive anecdotal feedback and the need for continued health coaching. In conclusion, this preliminary work creates the impetus for future large-scale lifestyle AD prevention investigations to improve the lives of AD-risk, low-income, diverse older adults. These findings demonstrate that telephone-based health coaching is feasible, based on participant engagement, and effective, based on positive trends in reducing AD risk factors.

DEMENTIA CAREGIVER SURROGATE DECISION MAKING SELF-EFFICACY, DISTRESS, AND QUALITY OF LIFE

Giovanna Pilonieta,¹ and David Geldmacher,² *1. University of Alabama at Birmingham, Birmingham, Alabama, United States, 2. University of Alabama at Birmingham, University of Alabama at Birmingham, Alabama, United States*

We assessed the relationship between caregiver self-efficacy and caregivers' ratings of care recipient's health-related quality of life, the severity of neuropsychiatric symptoms, and associated caregiver distress for persons with Alzheimer's dementia (AD). Methods: The 31-item DEMQOL-Proxy, Neuropsychiatric Inventory (NPI-Q), and the Self-Efficacy for Surrogate Decision-Making scale (SDM-SES) were collected from 26 family caregivers of people with AD expressing care resistant behaviors. We used Spearman correlations to assess relationships between SDM-SES, NPI-Q severity, and NPI-distress and DEMQOL-proxy. Among enrolled caregivers, 14 (54%) were women; mean age was 64.5 years, and 24 (92%) were college-educated. Their care recipients were 61% women, 77% white, with a mean age of 76 years, and mostly college-educated (88%). Mean scores were DEMQOL-Proxy 91.27 (+/- 14.16), SDM-SES 16.38 (+/- 2.74), NPI-Q Severity score 14.23 (+/- 6.04), and NPI-distress 17.42 (+/- 6.90). There were moderate correlations between DEMQOL-Proxy and SDM-SES ($r=0.54$), NPI severity ($r=-0.42$) and NPI-distress ($r=-0.49$). Secondary analysis showed a moderate correlation between SDM-SES and NPI-distress ($r=-0.40$). We identified associations between caregiver self-efficacy, quality of life, and caregiver distress. A higher baseline SDM-SES was associated with greater health-related quality of life for the care recipient. Lower self-efficacy scores were related to more caregiver distress related to neuropsychiatric symptoms. Higher NPI severity and caregiver distress were associated with lower quality of life for the care recipient. Interventions targeting self-efficacy may promote improved QOL and decrease caregiver distress in AD dyads.

DEVELOPMENT AND PSYCHOMETRIC TESTING OF CODING SCHEME FOR DEMENTIA FAMILY COMMUNICATION USING VIDEO OBSERVATION

Sohyun Kim, *University of Iowa, Iowa City, Iowa, United States*

Understanding communication behaviors between persons living with dementia and family caregivers is essential for meaningful social interaction and decrease problematic

behaviors and caregiving burden. The purpose of this study was to develop and test the psychometric properties of a coding scheme for dementia care interactions. The coding scheme items were developed from literature and expert review, and the pilot testing on 16 video-recorded interactions. A secondary analysis was conducted using 77 videos from 21 dyads of dementia family interactions naturally occurred in the participant's home. The final coding scheme consists of 11 codes for persons living with dementia (6 nonverbal and 5 verbal) and 12 codes for family caregivers (7 nonverbal and 5 verbal). Content validity was excellent (I-CVI = .93, S-CVI/UA = .71, S-CVI/Ave = .93 with 6 experts). Inter-item correlation was acceptable for both caregiver codes (positive nonverbal = .21, positive verbal = .15, negative nonverbal = .36, negative verbal = .29), and patient codes (positive nonverbal = .13, positive verbal = .27, negative nonverbal = .15, negative verbal = .18). Intra-rater reliability (Cohen's Kappa = .83, percentage of agreement = 83.88%) and inter-rater reliability (Cohen's Kappa = .81, percentage of agreement = 81.75%) were excellent. Findings suggest the preliminary psychometric properties of the newly developed coding scheme to assess dyadic interactions of persons living with dementia and their informal caregiver in-home care situations. Future testing of the coding scheme for application in communication interventions to improve quality social interaction in dementia care is discussed.

EXPLORING PARADOXICAL LUCIDITY STORIES: WORKING TOWARDS PROMOTING MEANINGFUL ENGAGEMENT WHEN LEAST EXPECTED

Regula Robnett, and Thomas Meuser, *University of New England, Portland, Maine, United States*

Lucidity is the typical cognitive state of adults. However, conditions such as Alzheimer Disease and major neurocognitive disorders can rob people of their usual clarity. Episodes of "paradoxical lucidity" (PL) happen when there is a spontaneous return of lucidity in people who are assumed to have lost the capacity to engage and communicate. These often take place near the end of life. Anecdotal stories depicting PL have been shared for centuries, but the etiology and mechanisms of PL rarely have been examined scientifically. The purpose of this mixed-methods project was to "gather the stories," of witnessed episodes of PL, to describe them, including potential triggers and contextual supports. Sixty witnesses of episodes have shared their experiences. Two-thirds those displaying PL were female. Most had died within six months of the episode. Episodes generally lasted under an hour (range: "moments" up to 5+ hours). Illustrative descriptions about PL emerged: 1) A trusted person or professional, perhaps unknowingly, saying or doing the right thing could trigger an episode; 2) PL frequently took place in a sacred environment involving ritual spiritual practices (e.g., saying the rosary and singing hymns); 3) meaningful music was often a trigger; and 4) PL sometimes involved the return of one's professional or familial/friend role. Familiar sounds (e.g., music, voices) were the most common sensory antecedents. A deeper understanding of PL events could potentially drive interventions to promote these valued episodes. The possibility that end-stage neurocognitive impairments could be reversible, even for a short period, is thought-provoking and inspiring.

EXPLORING WELL-BEING OUTCOMES AMONG PERSONS LIVING WITH DEMENTIA: SELF-REPORTS VERSUS CAREGIVER PROXY REPORTS

Morgan Minyo,¹ Sara Powers,² Alyssa Ciancibello,² Rachel Schaffer,² and David Bass,² 1. *Cleveland State University, Cleveland, Ohio, United States*, 2. *Benjamin Rose Institute on Aging, Cleveland, Ohio, United States*

A vast amount of research has focused on the development of dementia caregiving evidence-based programs (EBPs) in order to mitigate the well-known negative impacts of providing care for persons living with dementia (PLWD). In order to support efficacious results, many programs utilize a variety of both objective and subjective outcomes as typically reported by the caregiver or collected via medical history and clinical assessments. However, more recent research has attempted to understand the subjective illness experience of PLWD through self-report measures. Using data obtained from an online database (i.e., Best Practice Caregiving), that currently provides in-depth information on 44 dementia caregiving EBPs, the current study aimed to examine the number of EBPs that incorporated PLWD self-report measures on a variety of well-being outcomes. Results indicate that out of the 44 EBPs included for analysis: 1) Four out of 19 programs evaluating PLWD symptom severity/difficulty/distress used a PLWD self-report measure; 2) Eight out of 10 programs evaluating PLWD symptoms of depression used a PLWD self-report measure; 3) Five out of 10 programs evaluating PLWD quality of life/care utilized a PLWD self-report measure; and 4) One out of 9 programs evaluating ADL/IADL dependencies utilized a PLWD self-report measure. Discussion will focus on potential gaps and limitations of primarily using caregiver proxy reports to collect personal well-being outcomes for PLWD and ways in which researchers can integrate more self-report measures into intervention and programmatic evaluations.

FINDINGS FROM COMMUNITY WORKSHOPS DESIGNED TO HELP EXPAND ARIZONA'S DEMENTIA CAPABLE SYSTEM

DAVID Coon, Aylin Angulo, Marielysse Cortes, Berta Carbajal, Kassey Stotler, zenya Weatherall, and jami Goldman, *Arizona State University, Phoenix, Arizona, United States*

Among the 5.8 million people living with Alzheimer's disease (AD), there are three vulnerable groups where community partners can join efforts to serve the community more comprehensively. These include (a) people living alone with Alzheimer's disease and other related dementias (ADRD) who may or may not have a family caregiver, (b) people with Down Syndrome or another intellectual or developmental disability aging with ADRD and their family caregivers, and (c) people with ADRD and their family caregivers in the Latino community. Dementia capable systems are designed to address the needs and concerns of all individuals, families, and communities impacted by ADRD. The project develops and expands ADRD programs and services across Arizona through educational workshops, case management services, and evidence-based programs. Workshops (N=67) were provided to a variety of professionals and community members ranging from promotores/CHW's (community health workers) and case managers to family caregivers and people

living with dementia (N=2,272). Workshops successfully attracted a substantial proportion of Hispanic or Latino/a participants (63%) and women (84.5%). Perception of benefit ratings were overwhelmingly positive with over 90% of participants agreeing or strongly agreeing that: the workshops met expectations; they were willing to attend other programs by us; and they learned something they could use. Moreover, based on their workshop experience, they felt more confident that they could help these three underserved populations. Overall, workshops were clearly acceptable to participants and feasible to deliver. In addition, they contributed to an increased awareness in ADRD related to the project's three target groups.

FIRST: ENHANCING AGENCY DEMENTIA CAPABILITY THROUGH DEMENTIA-SPECIFIC INTERVENTIONS AND SUPPORTIVE SERVICES

Elizabeth Wellbrock, and Joanna Hutchinson, *County of San Diego Health and Human Services Agency, San Diego, California, United States*

Through the First Identify and Refer then Serve and Track (FIRST) Project, individuals and caregivers have critical connections to community organizations and resources to learn ways to handle living with memory problems. The FIRST project integrated new practices into existing programs to address gaps in service and piloted a new dementia-specific case management program. The initial intervention is a system-level change within the County of San Diego's Aging & Independence Services (AIS) department to identify, pilot, and implement a brief Alzheimer's Disease and Related Dementias (ADRD) screening tool. The tool was used by non-clinical personnel to identify potential ADRD cases. Individuals who screened positive for possible ADRD were referred to their physicians for an accurate diagnosis. The second intervention consisted of two components: a behavioral symptom management intervention for social workers to use in the home with caregivers and a dementia-specific case management program (including respite care) to improve quality of life and future planning for those with ADRD living alone or with a family caregiver. As of January 2021, 536 clients across several AIS programs have been screened for ADRD, of which, 60% screened positive. FIRST case management has served 196 clients, 70 who lived alone and 126 who lived with their caregiver. Respite was provided to 98 clients totaling to 3,666 hours. This poster evaluates the effectiveness of the program components in increasing dementia capability of an agency, and where applicable, its effect on caregiver burden and self-efficacy.

INTEGRATING ALZHEIMER'S MESSAGES INTO CHRONIC DISEASE PROGRAMS

Leslie Best,¹ Rebecca Drewette Card,² Lisa Garbarino,³ Christopher Taylor,⁴ Kimberly Boim,⁵ and Benjamin Olivari,⁴ 1. *National Association of Chronic Disease Directors, Decatur, Georgia, United States*, 2. *Public Health Partners, Topsam, Maine, United States*, 3. *Centers for Disease Control and Prevention (CDC), Atlanta, Georgia, United States*, 4. *Centers for Disease Control and Prevention (CDC), Atlanta, Georgia, United States*, 5. *CDC, Atlanta, Georgia, United States*

The number of people in the United States with dementia is increasing, with nearly six million people living

with Alzheimer's disease and related dementias. It is the fifth leading cause of death for those aged ≥ 65 years. Over 95% of people with dementia have another comorbid chronic condition. The Healthy Brain Initiative's State and Local Public Health Partnerships to Address Dementia: The 2018-2023 Road Map notes that public health agencies should raise awareness of the link between brain health and physical health, and specifically calls out tobacco prevention and control, cardiovascular health management diabetes prevention and management, obesity prevention and control, and injury prevention as intervention points. The National Association of Chronic Disease Directors developed brain health messages targeted to reduce risk for cognitive decline through the prevention and control of comorbid chronic conditions. These messages can be leveraged for public health action by integrating them into existing chronic disease programs.

PSYCHOLOGICAL CHALLENGES AMONG OLDER ADULTS WITH EARLY STAGE DEMENTIA: A NARRATIVE LITERATURE REVIEW

Mijin Jeong, *University of Kansas, LAWRENCE, Kansas, United States*

Due to rapid expected growth in the population of older adults with dementia, exploring the issues and experiences related to early stage dementia (ESD) is a fundamental step toward helping individuals adjust to their diagnosis and transition into treatment. The purpose of this paper is to review the extant literature regarding how older adults adjust to and cope with the onset of dementia through major situations and difficulties. A narrative approach was applied to review 120 articles focused on ESD that were published in the U.S. and other western countries between 1995 to 2020. There were four apparent themes in the literature, which align with key chronological experiences related to ESD: diagnosis of dementia; stigma related to dementia; the development of identity with ESD; and social and service-related experiences of older adults with ESD. Stigma related to dementia was a powerful risk factor that hindered psychological adjustment to ESD. Varied cultural perspectives on dementia and a lack of knowledge of dementia symptoms among diverse older adults and their families were also major risk factors. In the U.S., there was a lack of literature, especially around the development of identity with dementia and older adults' perspectives on available services. Also, there were insufficient U.S.-based studies that explored the challenges of psychological adjustment among racial and ethnic minority groups. Future research could benefit from taking a life course perspective to assess ESD within the context of one's life and examine challenges associated with ESD across all four themes to promote empowerment.

RELIGION AND SPIRITUALITY MEASURES IN DEMENTIA: AN INTEGRATIVE REVIEW OF THE LITERATURE

Katherine Britt,¹ Gayle Acton,² and Jung Kwak,³
 1. *University of Texas at Austin, School of Nursing, Austin, Texas, United States*, 2. *University of Texas at Austin, The, Austin, Texas, United States*, 3. *The University of Texas at Austin, Austin, Texas, United States*

Literature documents positive effects of religion and spirituality on health including improved cognitive function,

quality of life, and well-being. Extant research suggests that persons living with dementia (PWD) are more likely to have spiritual needs and rely on others to support their spiritual well-being than those without dementia. However, spiritual care is absent or minimally present in dementia care. To effectively address spiritual needs of PWDs, accurate screening and assessment is critical. We conducted an integrative review of the current literature on measures of religion and spirituality for PWDs by searching five databases (ATLA Religion, CINAHL, PsychInfo, PubMed, and SocIndex) and identified 14 studies that were peer-reviewed original research articles focusing on assessment of religion/spirituality among PWDs and published between 2000-2020 in English. Most were conducted in Europe (n=7), included PWD in mild stage (n=68) from various settings, and were cross-sectional in design (n=8). Of a total of 17 measures identified, 6 were originally developed for the general population and then adapted for PWD, and only 3 were validated for PWD. A majority of the studies were limited in sample size, generalizability, methodological rigor, and measure validation. More research is needed using diverse samples and rigorous study designs to develop valid screening and assessment tools for this population. Improving religious and spiritual measures could greatly impact public health by improving quality of life for millions of individuals suffering from dementia and their caregivers who carry a heavy burden.

SOCIAL DETERMINANTS OF HEALTH AND THE ONSET OF DEMENTIA IN LATER LIFE

Darren Liu,¹ Takashi Yamashita,² Betty Burston,³ and Chetana Guthikonda,¹ 1. *Des Moines University, Des Moines, Iowa, United States*, 2. *University of Maryland, Baltimore County, Baltimore, Maryland, United States*, 3. *University of Nevada, Las Vegas, Las Vegas, Nevada, United States*

Dementia is a debilitating neurodegenerative syndrome characterized by deterioration in memory, cognitive, behavioral, and physical capacity. Recent research has indicated that some early-life social determinants of health (SDH), which vary by race/ethnicity may hold clues to the onset of dementia. Although early life clinical risk factors of dementia have been identified, early-life SDH such as education, sociodemographic and socioeconomic characteristics are yet to be collated. This review study focused on early-life (less than 18 years of age) SDH in relation to cognitive decline in later life and differences across racial/ethnic groups in the U.S. A systematic review of articles in and after January of 1999 was conducted using Scoping Reviews - an approach for evidence synthesis to determine the coverage of a body of literature. Studies that report the impact of early-life social determinants on late-life cognitive decline were identified through the searches of CINAHL, Global Health, PsycINFO, PubMed and Scopus databases. Our initial database search resulted in 823 studies, and of those, 102 studies satisfied the inclusion criteria. The systematic review identified the following risk factors: lower education (34%), lower socioeconomic status (25%), Adverse Childhood Experiences (ACEs) (14%), exposure to environmental toxins (11%), food insecurity (6.8%), and rural residence (4%). Although education and socioeconomic status are well-known risk factors of cognitive decline in later life,

other understudied factors such as food insecurity and residing in rural areas are yet to be explored. Implications in terms of understanding the link between early life SDH and dementia in later life are discussed.

VIRTUES AND CHARACTER STRENGTHS IN PERSONS WITH MILD ALZHEIMER'S DISEASE AND RELATED DEMENTIAS

Jocelyn McGee,¹ and Michaela McElroy,² *1. Baylor University, United States, 2. Baylor University, Waco, Texas, United States*

The Values in Action (VIA) framework, from positive psychology, consists of 6 virtues (wisdom, courage, humanity, justice, temperance, and transcendence) which can be broken down into 24 strengths of character (Peterson & Seligman, 2004). Although this framework has been used to understand virtues and strengths in various populations, persons with Alzheimer's disease and other progressive dementias have been largely excluded from such studies. The aims of our study were to utilize the VIA framework to: 1) examine the expression of virtues and character strengths in a sample of persons diagnosed with probable AD (who were clinically designated as having mild disease based on neuropsychological assessment); and 2) provide implications for further strengths-based research and clinical practice with this population. Twenty-eight older adults, between the ages of 56 and 93 ($M = 77.88$, $SD = 9.88$), participated in the study. All had a Clinical Dementia Rating Scale (CDR) of 1 which suggested mild dementia. The Dimensions of Living with Dementia Interview (DLD; McGee & Carlson, 2013) was utilized for data collection. Interviews lasted approximately 45 minutes per participant. The interviews were professionally transcribed, audit checked, and uploaded to NVivo (2018) for analysis. Directed content analysis (Hsieh & Shannon, 2005) was utilized to extend the VIA framework to this sample. The virtues of wisdom, courage, humanity, temperance, and transcendence were demonstrated. We share how these virtues and corresponding character strengths can assist people with early-stage dementia in adaptation to the disease. Implications for clinical practice and further research are provided.

Session 9190 (Poster)

Dementia Prevalence and Risk Factors

A PATH ANALYSIS OF AGITATION IN PERSONS WITH ALZHEIMER DISEASE

Katherine Kero,¹ Hossein Yarandi,² and Debra Schutte,² *1. Institute of Gerontology, Wayne State University, Northville, Michigan, United States, 2. Wayne State University, Detroit, Michigan, United States*

This study tested a theory-driven path model of predictors and outcomes of agitated behavioral symptoms in persons with Alzheimer Disease (AD) guided by the Nursing Theory of Unpleasant Symptoms. This secondary analysis included data from 48 persons with AD from institutional residences in Midwestern United States. Data included measures of physical, psychological, and situational antecedents of agitation, the symptom of agitation, and

functional outcomes of agitation with 15 instruments and subscales. The data were a good fit for the empirical path model ($\chi^2 = 1.049$, $df = 2$, $p = .592$). Statistically significant paths were found from measures of physical, psychological, and situational antecedents to agitation ($B = 0.58$, 0.446 , and 0.51 ; $p \leq .001$) which explained 63% of the variance in agitation. Functional performance was influenced only by physical antecedents, which explained 66% of the variance in functional performance. While physical and psychological states may be comorbid to the AD disease process and therefore less modifiable, the situational measure was primarily defined by measures related to caregiver burden. Therefore, future agitation interventions should target strategies to improve caregiver burden.

BEHAVIORAL CORRELATES OF SUBJECTIVE COGNITIVE DECLINE IN THE CANADIAN LONGITUDINAL STUDY ON AGING (CLSA)

Shawna Hopper,¹ Nicole Hammond,² and Arne Stinchcombe,³ *1. Brock University, St Catharines, Ontario, Canada, 2. University of Ottawa, Ottawa, Ontario, Canada, 3. Brock University, St. Catharines, Ontario, Canada*

Subjective cognitive decline (SCD) is a self-reported decline in cognition among otherwise cognitively healthy older adults. It is believed that SCD may be a precursor to Alzheimer's Disease (AD). Analyzing data from the Canadian Longitudinal Study on Aging (CLSA), a large national sample of participants aged 45-85 at baseline, we sought to identify prospective relationships between health-related behaviors and SCD. Exposures were measured at baseline and SCD was measured three years later, with the question: "Do you feel like your memory is becoming worse?". A multivariable logistic regression model was used to estimate odds of SCD (analytic sample: $n=35,680$). Alcohol consumption was associated with increased odds of SCD, with regular drinkers ($OR=1.13$, 95% CI: 1.04, 1.22) and frequent drinkers ($OR=1.17$, 95% CI: 1.08, 1.27) more likely to report SCD than never drinkers. Compared to participants who never smoked, former smokers had increased odds of SCD ($OR=1.13$, 95% CI: 1.08, 1.18), whereas current smokers had reduced odds of SCD ($OR=0.90$, 95% CI: 0.83, 0.98). Participants who consumed five or more servings of fruits/vegetables had reduced odds of SCD ($OR=0.95$, 95% CI: 0.91, 0.99), when compared to those who consumed <5 servings. Lastly, we did not observe any associations between walking and SCD. This study identifies relationships between various health-related behaviors and SCD in a large population-based sample of older Canadians. Identification of modifiable risk factors may help with early prevention and intervention of SCD.

ESTIMATING DEMENTIA FROM SELF-REPORTS OF DIAGNOSES AMONG ADULTS AGED 65 AND OVER: UNITED STATES, 2019

Ellen Kramarow, *National Center for Health Statistics, Hyattsville, Maryland, United States*

Prior research shows that, overall, about 10% of the population aged 65 and over in the U.S. has dementia. Estimating the prevalence of dementia from nationally representative surveys can be accomplished by asking respondents

about a diagnosis, by administering a cognitive assessment, or, if available, by examining linked medical claims data. In 2019 for the first time, the National Health Interview Survey (NHIS) added “dementia, including Alzheimer’s disease” to the questions asking about doctor-diagnosed health conditions. Although estimates derived from doctor-diagnosed questions usually underestimate the true prevalence of a condition, and estimating dementia from self-reports presents additional challenges, they are still useful for many surveillance and research objectives. Early diagnosis of dementia is encouraged to allow patients and their families to plan for future needs. The objective of this research is to describe the noninstitutionalized population aged 65 and over who have a dementia diagnosis, by selected socio-demographic, health, and healthcare utilization characteristics. Point estimates, standard errors, and 95% confidence intervals for percentages are calculated using NHIS adult sample weights and adjusted for the complex sample design of NHIS. Preliminary analyses show that, overall, 4% of the 65 and over noninstitutionalized population has a diagnosis of dementia. About 8% of respondents with less than a high school education reported a dementia diagnosis compared with 2% of those with more than a high school education. Those with a dementia diagnosis were more likely to report depression than those without a dementia diagnosis (44% vs. 14%).

MOTORIC COGNITIVE RISK SYNDROME: ITS PROGNOSTIC VALUE FOR DEMENTIA AND OTHER HEALTH OUTCOMES. A SYSTEMATIC REVIEW

Donncha Mullin,¹ Alastair Cockburn,² Miles Welstead,¹ Michelle Luciano,³ Graciela Muniz-Terrera,¹ and Tom Russ,¹ 1. *University of Edinburgh, Edinburgh, Scotland, United Kingdom*, 2. *NHS Lothian, Edinburgh, Scotland, United Kingdom*, 3. *University of Edinburgh, Edinburgh, Scotland, United Kingdom*

Motoric cognitive risk syndrome (MCR) is a recently defined concept combining objective slow gait and subjective cognitive complaints, in the absence of dementia or significant functional impairment. MCR is associated with an increased risk for dementia but its prognostic value for other mental and physical health conditions is less studied. MCR is quick, inexpensive and easy to measure, making it a potentially useful clinical tool. This review aims to be the first to synthesise all mental and physical health outcomes associated with MCR since the term was coined in 2013. Results from multiple databases (MEDLINE, AMED, EMBASE, CINAHL, PsycINFO, and the Cochrane library; conception to November 2020) were screened independently and risk of bias was assessed. [Results are currently preliminary but definitive findings will be available in time for the conference] In total, 1057 references were screened, resulting in 34 studies being included, of which 14 will be meta-analysed. Eleven longitudinal studies examined MCR in relation to incident cognitive impairment or dementia conversion. Other prospective studies found that MCR predicted higher risk of mortality (n=2), falls (n=3), post-fall fractures (n=1), gait dysfunction (n=1), and cardiovascular risk factors and diseases (n=1). The results from the 23 cross-sectional studies reporting associations with MCR highlight areas for further study to better understand the biological mechanisms

of MCR. By synthesising the latest evidence, this review reinforces the value of MCR for predicting incident dementia, but also adds weight to its value in relation to other important age-related health outcomes.

MUSIC AND DEMENTIA: EXPLORING PROTECTIVE FACTORS FOR COGNITIVE FUNCTION

Sebastian Santana,¹ Michael Willden,¹ Debra Sheets,¹ Andre Smith,¹ Robert Stawski,² and Stuart MacDonald,¹ 1. *University of Victoria, Victoria, British Columbia, Canada*, 2. *Oregon State University, Corvallis, Oregon, United States*

Ample research suggests that musical interventions have the potential to boost social connection, engender positive emotions, and potentially buffer against depression in people with dementia (PwD). Here, our focus concerns expanding the present body of knowledge by quantifying the benefits of a music-based nonpharmacological intervention. The Voices in Motion (ViM) choir is an intergenerational sociocognitive lifestyle intervention designed to support caregivers and PwD. Over the course of 18 months, the well-being of PwD and caregiver dyads (N = 32; mean age = 79.6 years; 53% female) were rigorously assessed using an intensive repeated measures design. This project set out to determine whether positive change in the social dimensions of health (i.e., social connection [SC] and psychological well-being [WB]) ameliorates depression in PwD. Multilevel modeling was employed to examine longitudinal change within and between individuals. SC significantly predicted intraindividual change ($\Delta 20 = -0.48$, $p = .03$), with a predictive trend for between person differences ($\Delta 00 = -0.58$, $p = .08$). On occasions when PwD reported more SC, relative to their own baseline, they also reported fewer depressive symptoms. The effect associated with WB was significant at the between-person level ($\Delta 00 = -0.18$, $p = .01$). Our analysis suggests that a lifestyle intervention targeting psychological health and wellbeing may also contribute to the depressive signs and symptoms in PwD. As the current health care system is forced to adapt to social distancing and constant precautionary measures, it is crucial to understand and potentially harness the protective effects of modifiable lifestyle factors.

PREVALENCE OF DEMENTIA IN AMERICAN INDIAN/ALASKA NATIVE MEDICARE BENEFICIARIES

Heehyul Moon,¹ Richard MacLehose,² Joseph Kaholokula,³ Sunshine Rote,⁴ and Soonhee Roh,⁵ 1. *University of Louisville, university of Louisville, Kentucky, United States*, 2. *University of Minnesota, Minneapolis, Minnesota, United States*, 3. *John A. Burns School of Medicine, University of Hawaii at Manoa, Honolulu, Hawaii, United States*, 4. *University of Louisville, Louisville, Kentucky, United States*, 5. *University of South Dakota, Sioux Falls, South Dakota, United States*

Given the increase in life expectancy for American Indians and Alaska Natives (AIANs) due to many positive changes in social and environmental factors, the number of AIAN older adults with dementia is expected to grow from 23,850 in 2010 to over 100,000 by 2050. However, there have been few studies on the prevalence of dementia that have included AIANs. The purpose of the current study was to estimate the prevalence of dementia among AIANs over 65 years compared to non-Hispanic Whites (NHWs), Non-Hispanic Blacks (NHBs), Hispanics. The current study used survey data from Round 5 of the National Health and Aging Trends Study

(NHATS, 2015) (N=7,449), a nationally representative study of Medicare beneficiaries 65 years and older. We estimated the age and gender-adjusted prevalence of dementia and 95% confidence intervals for each race/ethnicity. The majority of participants were between 65 and 74 years old. Slightly more than half of them were female. AIAN Medicare beneficiaries showed a significantly higher prevalence of dementia than NHWs after adjusting for age and gender (4% greater or higher prevalence). We also observed a significantly lower prevalence of dementia in AIAN Medicare beneficiaries than NHBs, Hispanics. While previous research has reported that AIANs have a similar or lower prevalence of dementia than NHWs, our findings indicate significant dementia disparities in AIAN Medicare beneficiaries. Future research should focus on dementia prevalence and risk factors within/between AIAN tribes.

RACIAL/ETHNIC DIFFERENCES IN TRAJECTORIES OF DEMENTIA ONSET

Sunshine Rote,¹ and Heehyul Moon,² 1. *University of Louisville, Louisville, Kentucky, United States*, 2. *University of Louisville, university of Louisville, Kentucky, United States*

Racial and ethnic minority older adults—especially non-Latino Black and Latino older adults—continue to have a higher prevalence of dementia with longer delays in formal diagnosis compared to non-Latino Whites. Few studies have estimated racial/ethnic differences in trajectories of dementia onset using nationally representative data with representation from the three largest racial/ethnic groups in the U.S.: non-Latino White, non-Latino Black, and Latino older adults. Additionally, given the delays in formal diagnosis we rely on a measure of probable dementia that takes into account both formal diagnosis and cognitive function. Data from the National Health and Aging Trend Study (NHATS, 2011–2019) reveals three trajectories of dementia onset (early, late, and dementia-free) and we find that Latino and Black older adults are at greater risk for early dementia onset compared to non-Latino Whites. Our next step is to explore the role of social function for dementia disparities.

RISING GEOGRAPHIC VARIATION IN ALZHEIMER'S DISEASE MORTALITY

Yujin Franco,¹ and Jessica Ho,² 1. *University of Southern California, University of Southern California, California, United States*, 2. *University of Southern California, Los Angeles, California, United States*

The burden of Alzheimer's disease (AD) mortality has increased rapidly, growing by nearly 4- (men) and 6-fold (women) between 1990-2017. Limited attention has been paid to geographic inequalities in AD mortality. This study examines age-standardized AD mortality across 10 regions and the urban/rural continuum among adults aged 65+ using National Center for Health Statistics mortality and population data. We also examine mortality for a broader category, Alzheimer's disease and related dementias (ADRD), to address potential underreporting. The East South Central has the highest AD death rates and experienced larger increases—5-fold (men) and 7-fold (women)—than the nation as a whole. The Middle Atlantic consistently experienced the lowest AD mortality over the past quarter-century. Differences between the best- and worst-performing regions widened over time. AD mortality was 2.5 times higher in the East North Central than the Middle Atlantic region in 2017 (268 vs. 110 [men] and 374 vs. 147 [women]

deaths per 100,000). Rural areas facing health care shortages and socioeconomic deprivation may encounter substantial challenges in addressing rising AD mortality. In several regions, rural disadvantages in AD mortality emerged and widened over time. The largest gaps between nonmetros and large central metros are in the East North Central, South Atlantic, and New England, as well as Appalachia (men) and West South Central (women), with nonmetros having 14-56% higher mortality than big cities. These findings identify the heavy burden of AD mortality in the Southern and rural U.S. and have important implications for health care, service, and caregiving provision.

SELF-EXPERIENCED COGNITIVE FUNCTION IN THE DIGITAL ERA: ARE OLDER ADULTS AT RISK OF SUBJECTIVE COGNITIVE DECLINE?

Samantha Smith,¹ Moriah Splonskowski,² and Claudia Jacova,¹ 1. *Pacific University, Hillsboro, Oregon, United States*, 2. *Pacific University, Forest Grove, Oregon, United States*

Older adults often find it difficult to use everyday technology proficiently. We hypothesized that these difficulties would be exacerbated in those with subjective cognitive decline (SCD), that is, self-perceived worsening of cognitive functions that has been associated with increased risk of future dementia. Here we investigated the relationship between SCD symptom burden and technology proficiency. A nation-wide sample of adults (N=483) ages 50-79 (66.5% female; 14.5% age >70) completed an online survey via a crowdsourcing website, Amazon Mechanical Turk. The survey included the Subjective Cognitive Decline Questionnaire (SCD-Q MyCog) (0-25, M=4.71, SD=5.77), questions about respondents' proficiency with computer, smartphone, and tablet (4-12, M=9.72, SD=1.97), and the PROMIS depression (M=13.18, SD=6.32) and anxiety (M=13.04, SD=5.68) scales. Linear regression was used to examine the ability of technology proficiency to predict SCD score. We also probed the interaction of technology proficiency with age (<70 vs. >70 years), and adjusted for covariates. We found that the age/technology interaction (B=-0.80), older age (B=7.49), lower education (B=-1.08), higher depression (B=0.20) and anxiety (B=0.16) symptoms predicted higher SCD burden (R-squared=.16). For respondents >70 years low technology proficiency predicted high SCD burden (B=-.79) whereas for those <70 years no relationship was found. Our study draws attention to older adults' self-experienced cognitive function in the digital era. The association between low technology proficiency and SCD may signal the adverse impact of the digital era on those who experienced technology only later in life. It is equally possible that declining technology proficiency is an indicator of emerging neurodegenerative disease.

Session 9195 (Poster)

Driving and Older Adults

DOES USEFUL FIELD OF VISION PREDICT ATTENTION WHILE DRIVING BETWEEN YOUNG AND OLDER ADULTS?

Rebecca Dunterman,¹ and R INTRIERI,² 1. *Auburn University, Auburn, Alabama, United States*, 2. *Western Illinois University, Macomb, Illinois, United States*

The Insurance Information Institute (2017) reports drivers aged 65 and up are involved in the second highest rate of fatal car crashes. It is important that there is a fair and standardized assessment to test driving fitness. The prime objective was to assess the utility of the Useful Field of View (UFOV) across young and old groups to predict performance on a simulated driving exercise. Community-dwelling adults aged 65 and older ($n=48$) and students ($n=48$) recruited from an undergraduate research pool served as participants. They completed a series of demographic, health and cognitive measures, besides a Useful Field of Vision (UFOV) task and a driving simulation exercise. Results showed that collision avoidance and braking varied between age groups, with older adults appearing to be less likely to avoid collision (Older $M = 12.46$, $SD = 10.25$, Younger ($M = 7.96$, $SD = 4.92$; $n = 47$), but quicker to brake (Older $M = 3.64$, $SD = 3.41$, Younger $M = 9.79$, $SD = 7.91$). There were group differences for driving simulator performance, predicted by cognitive measures (Young; $R^2 = .099$, $p = 0.005$; Old; $R^2 = 0.094$, $p = 0.038$). UFOV scores did not predict group differences in driving simulator performance (Young; $R^2 = 0.009$, $p = 0.664$; $\beta = 0.089$, $p = 0.437$), (Older; $R^2 = 0.061$, $p = 0.522$; UFOV-DA $\beta = -0.074$, $p = 0.555$; UFOV_SA $\beta = 0.289$, $p = 0.194$). These findings have implication for the development of pragmatic capacity to drive assessments.

DRIVING FREQUENCY AND WELL-BEING IN OLDER ADULTHOOD

Zainab Suntai, Kefentse Kubanga, Abhay Lidbe, and Emmanuel Adanu, *University of Alabama, Tuscaloosa, Alabama, United States*

The activity theory of aging suggests that older adults age successfully when they remain active and engaged. While many older adults are still able to drive, not all are as engaged in social activities, despite having the transportation to be able to do so. As such, this study aimed to examine the association between the frequency of driving and overall well-being among older adults. The hypothesis is that older adults who drive more frequently would have higher well-being, as they are likely driving to engaging activities. A sample of 1,663 older adults who reported that they are able to drive were derived from the 2018 National Health and Aging Trends Study (NHATS). The NHATS is an annual longitudinal panel of survey of adults aged 65 and older living in the United States. Chi-square tests were used for bivariate analyses and a weighted multivariable logistic regression model was used to predict well-being based on driving frequency. Results showed that compared to those who drive every day, those who drive most days ($OR=0.771$, $CI= [0.768-0.775]$), some days ($OR=0.495$, $CI= [0.492-0.497]$), rarely ($OR=0.558$, $CI= [0.555-0.562]$) or never ($OR=0.371$, $CI= [0.367-0.374]$) were less likely to have high well-being. Interventions geared at improving well-being among older adults should therefore consider increasing awareness of social events, to ensure that older adults who are able to drive can have a good quality of life by driving to social activities.

DRUGGED DRIVING AMONG SEXUAL MINORITY OLDER ADULTS IN THE UNITED STATES, 2015-2019

Jie Yang,¹ and Andrew Yockey,² *1. East Carolina University, Greenville, North Carolina, United States, 2. University of*

North Texas Health Science Center, Denton, Texas, United States

Introduction: Drugged driving, the act of operating vehicles under the influence of one or more illicit substances is responsible for numerous emergency department visits, deaths, and increased medical costs. Despite higher instances of drug use, older sexual minority (LGB) adults are often neglected in prevention efforts. This study assessed inequities between sexual minority older adults and their heterosexual counterparts in drugged driving across three difference substances (alcohol, marijuana, other drugs). Methods: Pooled data from individuals 50 years or older ($n = 43,238$; 1,115 sexual minority adults) in the 2015–2019 National Survey on Drug Use and Health were analyzed. Past-year driving under the influence of alcohol, marijuana, and illicit drugs were outcome variables, and survey-weighted frequencies with 95% confidence limits and crude ORs with 95% confidence intervals (CI) were estimated. Results: In the past year, 4.82% of older adults drove under the influence of alcohol, 1.33% drove under the influence of marijuana, and 1.48% drove under the influence of illicit drugs. Sexual minority adults consistently showed higher odds of drugged driving than their heterosexual counterparts, with individuals who identify as bisexual being most at risk for driving under the influence of illicit drugs (aOR:4.49, 95%CI: 2.84, 7.08) and marijuana (aOR:3.95, 95%CI: 2.39, 6.51). Discussion: There are differences drugged driving by sexual orientation across the three substances we assessed. These rates of substance use among older sexual minority adults warrant ongoing concern, and it is critical to consider differences across the life course in designing and evaluating interventions to address inequities.

UNDERSTANDING DRIVING AVOIDANCE AMONG OLDER AFRICAN AMERICANS AND WHITES WITH DIABETES

Henrietta Armah,¹ Maya Martin,² Wesley Browning,¹ Ghislaine Atkins,¹ and Olivio Clay,¹ *1. University of Alabama at Birmingham, Birmingham, Alabama, United States, 2. Tuskegee University, Tuskegee, Alabama, United States*

Diabetes mellitus is one of the most common chronic diseases with half of the new diagnoses affecting adults aged 60 years and older. Although African Americans are more likely to develop the disease, they are also less likely to receive healthcare. Importantly, living with diabetes is likely to negatively impact mobility for aging adults as the disease is associated with lower physical functioning (e.g., ability to maintain one's balance). Further, diabetes could pose a significant threat to a person with diabetes' ability to drive and remain in the community. This study examines the relationships and influences of social determinants of health (e.g., race, gender, socioeconomic status) and cognition on avoiding driving maneuvers such as driving at night and in rush hour traffic among older adults with diabetes. Data from the University of Alabama at Birmingham (UAB) Diabetes and Aging Study of Health (DASH) were analyzed and of the 224 participants, 193 (86.16%) were current drivers. There was a gender difference with 94.12% of males and 79.51% of females being current drivers, $p < .01$. Within the sample of current drivers, 45% were African American and being female, not married, lower levels of education and

cognition, low income, and being African American were associated with higher scores on driving avoidance. Cognition explained 30.44% of the racial difference in driving avoidance. Findings from this study will help identify individuals who are at-risk for reduced mobility and identify those who may need to be intervened upon to support a better quality of life.

Session 9200 (Poster)

Dyadic Research (BSS Poster)

A DYADIC STUDY OF DEPRESSION, CAPITALIZATION PATTERNS, AND LEISURE ACTIVITIES IN RETIREMENT

Ksenya Shulyaev,¹ Dikla Segel-Karpas,² and Nurit Gur-Yaish,³ 1. *Faculty of Social Welfare and Health Science, University of Haifa, Haifa, Hefa, Israel*, 2. *University of Haifa, Haifa, Hefa, Israel*, 3. *Oranim Academic College of Education, Haifa, HaZafon, Israel*

Late-life relationships, and specifically spousal relations, are increasingly recognized as an important factor shaping the wellbeing, health, social and emotional health of older people. Therefore, a better understanding of the health and well-being trajectories of older adults requires considering the characteristics of their spouses and couple dynamics. This study focused on the actual problem of engagement of recently retired older adults in the community and various leisure activities and examined how both older adults' and spouses' depression level influence their activities. We also consider the quality of relationships in a couple: how a partner generally responds when the participant discloses good news (capitalization). Fifty-three Israeli couples participated in the current study with one member of the couple 60 or older and retired within the last five years. Recently retired spouses rated their engagement in leisure activities, both spouses reported their level of depression, and partners of retired persons completed the Perceived Responses to Capitalization Attempts Scale. Results show that depression level of recently retired spouses had a direct negative effect ($b(SE)=-7.8(3.38)$, $CI(-14.65,-1.04)$, $p=0.02$) on their engagement in leisure activities, while the level of their partners' depression had no significant direct effect on retired persons' leisure activities. However, partners' depression associated ($p=0.001$) with negative capitalization patterns and mediation analysis showed an indirect effect of partners' depression via the capitalization ($b(SE)=-2.77(1.7)$, $CI(-6.41,-0.04)$, $p=0.03$). These results indicate that in encouraging newly retired people to participate in leisure activities it is important to consider both spouses' depression level and capitalization patterns in the couple.

“I’M GETTING OLDER TOO”: CHALLENGES AND BENEFITS EXPERIENCED BY VERY OLD PARENTS AND THEIR CHILDREN

Kathrin Boerner,¹ Yijung K. Kim,² Elizabeth Gallagher,³ Kyungmin Kim,⁴ and Daniela Jopp,⁵ 1. *University of Massachusetts Boston, Boston, Massachusetts, United States*, 2. *The University of Texas at Austin, Austin, Texas, United States*, 3. *University of Massachusetts Boston, Boston, MA*,

Massachusetts, United States, 4. *Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 5. *University of Lausanne, Lausanne, Vaud, Switzerland*

Very old parents and their “old” children are a growing group in industrialized countries worldwide. Since most very old persons have outlived spouses and friends, their children, many of whom have reached old age themselves, are likely to become their primary social contact and to shoulder the care provision role. However, virtually nothing is known about the nature and implications of this relationship constellation. To fill this gap, the present study explored the challenges and rewards of the very old parent-child relationship. In-depth interviews were conducted with 114 parent-child dyads (parent age ≥ 90 ; child age ≥ 65). Narrative interview data on challenges and rewards were audiotaped, transcribed, and then systematically reviewed and coded, identifying recurrent themes and defining categories that reflected these themes. While both challenges and rewards were present, more rewards than challenges were reported overall. However, comparing parent and child perspectives revealed that the balance of challenges and rewards was less favorable for children. Narrative data further showed that the sense of burdening their children heavily weighed on at least a fourth of parents, reflecting this as a serious concern not only for children but also for parents. Challenges reported by children were often characterized by references to children's own advanced age and health problems, and the prolonged caregiving involvement due to their parents' longevity. Healthcare professionals, policy makers, and families should be made aware of this increasingly common phenomenon, and specific services and policies will be needed to adequately support very old adults and their families.

CHARACTERISTICS OF OLDER ADULTS WHO RECEIVE ASSISTANCE WITH MANAGEMENT OF MULTIDRUG REGIMENS

Rachel O'Connor,¹ Julia Yoshino Benavente,¹ Mogan Eifler,¹ Lauren Opsasnick,¹ Laura Curtis,¹ Lee Lindquist,² and Michael Wolf,¹ 1. *Northwestern University, Chicago, Illinois, United States*, 2. *Northwestern University Feinberg School of Medicine, Chicago, Illinois, United States*

Many older adults manage multiple chronic conditions requiring adherence to multidrug regimens, yet half are non-adherent, increasing their risk of hospitalization for poorly controlled chronic conditions. Few studies have investigated whether caregivers support medication-related behaviors of community-dwelling older adults. We interviewed 97 patient-caregiver dyads participating in a cognitive aging cohort study to identify factors associated with caregiver assistance in managing multidrug regimens. Patients completed a neuropsychological battery covering five cognitive domains. Health literacy and patient activation were measured using the Newest Vital Sign and Consumer Health Activation Index, respectively. Caregivers reported their medication-related involvement. Predictors of involvement in medication-related tasks were examined using logistic regression models. Patients were on average 71 years old, managing 4 comorbidities and prescribed 5 medications. The majority were female (73%) and identified as Black (46%) or White (47%). Caregivers' mean age was 65 years; half were female (53%), were predominantly spouses (57%) or

children (26%), and lived with the patient (61%). 31% of caregivers ordered patients' prescribed medications, 40% helped manage their medications, and 50% spoke with the patient's clinician about their clinical care. Cognitive impairment (OR 2.60, 95% CI 1.08-6.25), limited health literacy (OR 2.97, 95% CI 1.26-6.97), and ≥ 3 comorbidities (OR 2.14, 95% CI 1.06-9.30) were associated with medication management assistance. Patient activation, gender, cohabitation, or relationship were not associated. These findings suggest that caregivers are assisting with older adults' medication management and should be included in clinical discussions about medication management, especially among patients with cognitive impairment, low health literacy or multimorbidities.

DYADIC LONELINESS AND HbA1C LEVELS AMONG OLDER MARRIED COUPLES: EVIDENCE FROM THE IRISH LONGITUDINAL STUDY ON AGEING

Jeffrey Stokes,¹ and Adrita Barooah,² 1. *University of Massachusetts Boston, Boston, Massachusetts, United States*, 2. *UMass Boston, Boston, Massachusetts, United States*

Loneliness is an important determinant of health and mortality among the aging population, including for cardiometabolic health. Yet research has largely focused on individual experiences of loneliness, rather than taking intimate relationships into account. However, recent studies have highlighted that the psychosocial well-being of one's partner may impact one's own health as well. Indeed, the stress generation hypothesis anticipates that loneliness in one partner may lead to more stressful interactions within relationships, and thus to worse health outcomes for both spouses. This is particularly true among older couples, as life events and shifting time horizons (e.g., retirement, socioemotional selectivity, reduced social networks) lead older persons to focus more time and energy on their closest relationships. Life events such as retirement may make adults' intimate relationships – and the experiences of their partner – more salient than ever before. In this study, we use dyadic structural equation modeling to examine associations between loneliness and HbA1c levels among 1,331 older married couples from The Irish Longitudinal Study on Ageing. Further, we test whether any such associations vary by age or employment status. Results indicate that one's own loneliness was not significantly linked with elevated HbA1c, irrespective of age or employment status. However, loneliness of a dyadic partner was significantly associated with elevated HbA1c among retired persons only. Further, this effect was not due to age, but rather to employment status itself. These findings suggest that relationship context is crucial when considering the dyadic health implications of loneliness among the older population.

DYADIC SUCCESSFUL AGING AND THE LIMITS OF AGENCY

Markus Klingel, *TU Dortmund University, Germany*), *Dortmund, Nordrhein-Westfalen, Germany*

With increasing life expectancy, late life has become a longer, crucial part of the individual and dyadic life course. New opportunities, tasks and decisions emerged. Successful aging norms emphasize agency and autonomy. This can be

activating, but also alienating. With increasing constraints, agency is limited and ideals of autonomy become dysfunctional. This challenges also relationships. Aging, functional losses and approaching death threaten dyadic satisfaction and functionality. Potentially, successful aging norms could erode dyadic solidarity when needed the most: in late life. This mixed-methods longitudinal study combines interviews and questionnaires at three observations across five years. Its focus lies on change over time and findings at observation three. The sample consists of eight German couples (78-86 years old, 50-65 years married, high relationship satisfaction, white, urban). What does aging mean for individualized actors? How do aging couples negotiate, decide and act on aging, autonomy and death? How do successful aging norms modulate dyadic aging? Overall, actors have internalized successful aging and benefit by influencing their health positively. However, this has become ambivalent. Actors increasingly perceive their future as limited and beyond individual control. Acceptance of losses that challenge the self is difficult, autonomy ideals burdensome and death salient. As individual agency is constrained, the dyad is still a functional stronghold against aging. Yet, it has to adapt as well to – potentially differential – individual aging. Losses can and do threaten couples' functional and emotional unity. Four patterns of self-dyad dynamics emerged and exemplify tensions between individualized and dyadic successful aging.

EXPLORING COLLABORATION ENJOYMENT AND DECISIONAL UNCERTAINTY: ACTOR-PARTNER EFFECTS IN ADVANCED CARE PLANNING

Shirin Hiatt,¹ Jia-Wen Guo,² Lee Ellington,² and Djin Tay,² 1. *Oregon Health & Science University, Portland, Oregon, United States*, 2. *University of Utah, Salt Lake City, Utah, United States*

Caregivers are often engaged in decision making with and for patients. However, the role of patient-caregiver interpersonal processes on decisions about advance care planning (ACP) are not well known. This secondary data analysis examined the effects of patient-caregiver enjoyment about collaboration regarding choices for life-sustaining treatment on patients' and caregivers' decisional uncertainty following a dyadic ACP intervention. A purposive sample of 18 adult home health patients and their informal caregivers (N=36) participated in a one-group pretest posttest study. The Interpersonal Enjoyment subscale of the Perceptions of Collaboration Questionnaire and the Decisional Uncertainty subscale of the Decisional Conflict Scale were administered using parallel questionnaires. The Actor-Partner Interdependence Model (APIM) was used to examine actor and partner effects of patients and caregivers' interpersonal enjoyment on their uncertainty in decisions about ACP before and after the intervention. The mean age was 68.2±9.6 years for patients and 61.3±13.6 years for caregivers. The majority of patients (61.1%) and caregivers (72.2%) were female and married (55.6% and 66.7%, respectively). Almost all were non-Hispanic White (97.0%). Patients' and caregivers' interpersonal enjoyment and uncertainty scores were similar before the intervention. A significant partner effect between greater interpersonal enjoyment among caregivers at pretest and greater patient uncertainty at posttest ($\beta=0.44$, $p=.037$) was found. Previous analyses found that overall patients

improved in decisional uncertainty at posttest. However, these findings suggest that for some dyads, interpersonal factors can negatively affect patients' decisional certainty. Future research is needed to verify this finding with a larger sample.

FAMILY PROXIMITY AS A MODERATOR OF SPOUSAL ASSOCIATIONS OF DEPRESSION AMONG MEXICAN OLDER ADULTS

Katie Newkirk,¹ Maria Aranda,² Catalina Mourgues-Codern,¹ Ana Quiñones,³ Rafael Samper-Ternent,⁴ and Joan Monin,⁵ 1. *Yale University School of Medicine, New Haven, Connecticut, United States*, 2. *University of Southern California, Los Angeles, California, United States*, 3. *Oregon Health & Science University, Portland, Oregon, United States*, 4. *The University of Texas Medical Branch, Galveston, Texas, United States*, 5. *Yale School of Public Health, New Haven, Connecticut, United States*

Depression among older adults is a public health issue, and a large literature highlights the importance of close relationships as both a risk and protective factor for depression. Research in U.S. samples suggests that one spouse's depressive symptoms can increase their partner's depressive symptoms, especially for women (Kouros & Cummings, 2010; Tower & Kasl, 1996). Little is known about interpersonal associations in depression, mitigating factors, and the role of gender among older couples in Mexico. This study examined (1) the effects of an individual's depressive symptoms on their spouse's symptoms and 2) whether living close to family buffered depression associations using data from the Mexican Health and Aging Study (n=4,071 dyads, age 50+ at initial interview). Depressive symptoms were measured in 2001, 2003, 2012, 2015, and 2018 using a modified 8-item version of the Center for Epidemiologic Studies-Depression Scale. Multilevel modeling was used to fit a dual-intercept growth model (centered at 2012) of husbands' and wives' depressive symptoms over time, controlling for age and education. Results showed a partner effect for husbands and wives, such that having a spouse with greater depressive symptoms in 2001 was associated with greater subsequent depressive symptoms, but not with rate of change in symptoms, in 2012. There was also a moderation effect such that the deleterious effect of husbands' depressive symptoms on wives' symptoms, as well as rate of increase in symptoms, was higher when family lived nearby, suggesting family may potentially exacerbate depression associations among spouses rather than a buffering them as hypothesized.

NOT SEEING DOUBLE: DISCORDANCE IN DISEASE, FUNCTION, AND THEIR LONGITUDINAL ASSOCIATIONS IN MONOZYGOTIC TWINS

Elizabeth Teas,¹ Olivia Robertson,² Kristine Marceau,² and Elliot Friedman,² 1. *Purdue University, West Lafayette, Indiana, United States*, 2. *Purdue University, Purdue University, Indiana, United States*

Prior research on the causality and directionality between disease and functional limitations is ambiguous. The current study used longitudinal monozygotic twin data to test both directions linking disease burden and functional limitations in middle-aged and older adults, controlling for genetic and

familial factors. We also examined potential moderation by psychological well-being. The Twins sub-sample from the first two waves of the longitudinal Midlife in the United States (MIDUS) study was used (Wave 1: 1995-1996, Wave 2: 2004-2006). Only monozygotic twins (N = 713) were included in analyses. In separate multi-level models, we examined disease burden at MIDUS 2 predicted by functional limitations at MIDUS 1 and MIDUS 2 functional limitations predicted by disease burden at MIDUS 1. Disease burden and functional limitations at MIDUS 2 varied substantially within families. There was no within-family association of earlier functional limitations with change in later disease burden (b = .40, p = .39), but there was a within-family association such that the twin with higher baseline disease burden had a greater increase in functional limitations than his/her co-twin (b = .06, p = .02). Well-being was not a moderator in either model. We found support for a potentially causal association between earlier disease burden and later increases in functional limitations, consistent with the Disablement Process Model. Sensitivity analyses confirm the detected within-family effect. Possible mechanisms linking disease burden and functional limitations are discussed as potential targets for future research.

RELATIONSHIP FUNCTIONING AND GUT MICROBIOTA COMPOSITION AMONG OLDER ADULT COUPLES: FEASIBILITY OF DATA COLLECTION

Shelby Langer,¹ M. Aaron Guest,² Melissa Tolson,² Juan Maldonado Ortiz,³ John DiBaise,⁴ Helene Labonte,⁴ and Rosa Krajmalnik-Brown,³ 1. *Arizona State University The College of Nursing & Health Innovation, Phoenix, Arizona, United States*, 2. *Arizona State University, Phoenix, Arizona, United States*, 3. *Arizona State University, Tempe, Arizona, United States*, 4. *Mayo Clinic, Scottsdale, Arizona, United States*

An emerging area of research extends work on couple functioning and physical health to gut health, a critical marker of general health and known to diminish with age. As a foray into this area, we conducted a pilot study to determine feasibility of data collection (questionnaires and a stool sample) among older adult couples. Participants were recruited from the community using a variety of methods including social media. Among 41 persons responding with interest across recruitment sources, 32 were contacted for screening. Inclusion criteria were: age 60+, marriage or cohabiting partnership, and English speaking/understanding. Exclusion criteria were a gastrointestinal disorder, receiving enteric nutrition, use of antibiotics (past month), cancer treatment (past 6 months), and a +COVID-19 diagnosis (past 2 months). Among 31 eligible couples, 30 consented. All 60 participants completed questionnaires and provided a stool sample using DNAgenotek's OMR-200 collection kit, chosen for its ease and because samples can be stored at room temperature for 60 days. Sample characteristics were: M (SD) age = 66.57 (4.78); 53.3% female; 91.7% White; 1.7% Latinx; and 78.3% college-educated. 2 couples were same-sex. 43% reported at least one health condition and 25% reported use of a proton pump inhibitor (which can affect the gut microbiome), though none daily. Relational well-being was moderate-high on average per measures of

dyadic adjustment and intimacy. Despite original plans to recruit couples in-person from a retirement community, remote operations were feasible via online assessment and study-coordinated shipping, a necessary yet fruitful shift due to the SARS-CoV-2 pandemic.

THE IMPACT OF SELF- AND RELATION-INFERRED EFFICACY ON PHYSICAL ACTIVITY IN OLDER ADULT COUPLES

Tiana Broen,¹ Yoonseok Choi,¹ Denis Gerstorff,² Maureen Ashe,³ Kenneth Madden,¹ and Christiane Hoppmann,³ 1. *University of British Columbia, Vancouver, British Columbia, Canada*, 2. *Humboldt University of Berlin, Humboldt University of Berlin, Brandenburg, Germany*, 3. *University of British Columbia, University of British Columbia, British Columbia, Canada*

Previous research has indicated that physical activity (PA) is a health-promoting behavior that is closely linked in couples. However, few studies have examined how PA is intertwined among couples in their everyday lives. For example, relation-inferred efficacy (RIE) is an individual perception that captures whether a close other believes in one's own abilities to perform specific behaviours; it originates from the sports literature on coach-athlete dyads and has been shown to shape athlete performance. Applying a repeated daily life assessment design, the current study targets self-efficacy (SE) and relation-inferred efficacy (RIE) as predictors of PA in older adult couples, as well as potential moderators when obstacles occur. We hypothesized that: (a.) There is a main effect of SE and RIE on PA. (b.) PA is lower on days when people anticipate barriers (c.) SE and RIE moderate the time-varying relationship between PA and barriers. Heterosexual couples (N=108 couples, Mage=70.5 years, SD=6.70) rated their SE and RIE, completed daily electronic questionnaires asking about barriers and wore an accelerometer to capture indices of PA across seven days. In line with past work, SE ($r(2438)=-.13$, $p<.001$) and RIE ($r(2438)=-.14$, $p<.001$) were significantly related to total moderate-to-vigorous PA (MVPA) and step counts. A series of multilevel models were fit to examine the hypotheses. Preliminary analyses indicated that RIE (estimate=3.93, SE=1.49, $p=.009$) is a stronger predictor of MVPA than SE (estimate=2.83, SE=2.02, $p=.16$). Further analysis will be conducted to unpack daily life circumstances that create barriers to PA, including daily pain, anxiety, and tiredness.

Session 9205 (Poster)

Education and Attitudes about Aging

AN OUNCE OF PREVENTION: REDUCING AGEISM THROUGH THE LENS OF PUBLIC HEALTH

Erin Grinshteyn, *University of San Francisco, San Francisco, California, United States*

Ageism is pervasive. The negative consequences of ageism are vast, and the literature on the effects of ageism on health and health care is extensive. The perpetrators of ageism are equally vast. While it may be tempting to believe that those who go into the fields of gerontology and geriatrics are free from these attitudes and behaviors, this is untrue.

It is reasonable to suspect that future public health professionals, even those interested in gerontology, may also carry ageist ideas and practices into their professional careers. This research was developed to determine whether teaching about aging and ageism in a public health course could reduce ageism among students. Participants were students in a class on aging and public health. All students were graduate students in a Master of Public Health (MPH) program. Multiple assessments were used to assess ageism including the Framboni Scale of Ageism (FSA), a validated 29-question measure used to assess ageism, and the Succession, Identity, and Consumption (SIC) scale, another scale assessing ageism. Students were enrolled in an elective course on aging and public health, which was taught through the public health lens of disease prevention and health promotion. Health topics related to aging are discussed with an emphasis on prevention. The contributions older adults make, and the resulting improved health and well-being of self, others, and community are promoted. And the class participates in activities with a variety of community-dwelling older adults. Results show that ageism among students is reduced after the semester long course.

COLLEGE STUDENTS' IN JAMAICA OPINION ABOUT OLDER ADULTS AND THEIR ROLE AS FUTURE CAREGIVERS: CASE EXAMPLE

Sharon McKenzie,¹ and Sandra Latibeaudiere,² 1. *Kean University, Union, New Jersey, United States*, 2. *University of the West Indies, Kingston, Kingston, Jamaica*

Ageing is a natural human experience, yet for many people getting old provoke fears of vulnerability, fragility, undesirability, and incapacity. Such perceptions are often attributed to various taboos, prejudices, discrimination and stereotype associated with old age. The purpose of this study was to assess college students' in Jamaica opinion about older adults and their role as future caregivers. Specifically, the study sought to: (1) identify whether college students hold ageist stereotype/negative image about older adults and whether they influence future role as caregiver, 2) assess their knowledge of the chronic conditions that affect older adults, and 3) assess whether they see themselves working or taking an active role in future caregiving. As we think about the future directions of healthcare provision for older adults, this small sample of college students provided a discourse about ageing and key elements that are important for educators in a developing country such as Jamaica to consider when building a gerontology curriculum.

DEVELOPING AN EDUCATIONAL PROGRAM ON AGING FOR HIGH SCHOOL STUDENTS

Tracy Davis,¹ and Amanda Sokan,² 1. *Rutgers University, New Brunswick, New Jersey, United States*, 2. *The University of Arizona, University of Arizona, Arizona, United States*

College students in disciplines that might provide services or work with older adults, such as medicine or social work, are usually the target of most educational programs on aging. High schools provide an untapped opportunity to engage students earlier. This project is the next step following a pilot study conducted in New Jersey and Kentucky to better understand high school students' attitudes and knowledge

regarding aging. That study also reviewed current high school curriculum for aging-specific content and perceived barriers among teachers to incorporating aging education into the curriculum (Davis & Sokan, 2019). Study findings indicate inter alia, a need to educate high school students about aging, increase interactions among older and younger adults, incorporate education about careers on aging, and educate teachers on how to infuse more aging content into their courses. To that end, this project's goal was to develop both a training module and educational program on aging for high school students. Also, we propose a plan to develop, implement, and evaluate both the training module and the educational programs. We hypothesize that the training module will increase high school teachers' confidence in their ability to teach their students about aging. The educational program's delivery will increase students' knowledge of aging-related issues and awareness about careers in aging. Upon completing the project, we will use feedback from students and teachers to revise the educational program, for implementation among a larger sample of high schools.

EVALUATING A GERIATRIC EDUCATIONAL PROGRAM: EXPLORING OPPORTUNITIES FOR INCREASING IMPACT AND SCALE

Shera Hosseini, Michelle Howard, and Allison Ward,
McMaster University, Hamilton, Ontario, Canada

The geriatric population is rapidly growing, and this growth is beyond the pace of increase in the number of healthcare professionals who are qualified to care for and tend to the various needs of this significant subgroup of the population. The current university curricula have not been sufficient in terms of quantity as well as their ability to address the ageism inherent in the perspectives of students from across the educational spectrum. In recognition of the absence of standardized geriatric guidelines, medical associations across Canada and the United States have established geriatric learning competencies for medical programs. Nevertheless, there are exiting gaps regarding the development and evaluation of geriatric-focused didactic programs that adequately train and build competency among the students interested in pursuing careers with geriatric-specific elements. A university-wide program was developed to enhance aging education and build competency through sparking interest, providing better education related to aging, and building better relationships between future healthcare professionals and older adults. To evaluate the impact of this program, a logical framework was developed a-priori and revised through constant iterations and following discussion with the program's multidisciplinary stakeholder group. Quantitative measures are being augmented with in-depth qualitative interviews to explore elements influencing students' experiences with the program and the effect on their interests in and attitudes towards geriatrics. The results will inform our conclusions regarding program effectiveness in enhancing interest in geriatric-focused education among the students and trainees and assist with recommending future directions regarding impact and large-scale dissemination and implementation.

PREDICTING STUDENTS' INTEREST IN AGING-RELATED CAREERS: SUGGESTIONS FOR PEDAGOGICAL INTERVENTION

Chih-ling Liou, *Kent State University, North Canton, Ohio, United States*

College students often hold negative attitudes toward elders and rank this area of practice at the bottom of their future professional life; colleges and universities have an important role to play in changing attitudes and attracting more professionals to work with older adults. This study examined factors contributing to students' attitudes toward older adults to provide suggestions for pedagogical intervention. Data was collected from 195 undergraduates participating in an online survey with questions on the quality of relationships with a grandparent and other nonfamilial older adults, previous experience and future interest in pursuing a career in an aging-related field, and The Fabroni Scale of Ageism (Fabroni et al., 2010). Path analyses using hierarchical multiple regression revealed that high quality relationships with older adults (i.e., both grandparents and nonfamilial elders) was associated with less negative attitudes and more interest in pursuing a future career in age-related jobs/internships. Although both types of relationship quality were significant in the model ($p < .05$), path coefficients demonstrated that relationships with nonfamilial elders have a greater impact on participants' attitudes ($\beta = -.250, p = .001$ versus $\beta = -.146, p = .045$). Previous working/internship experiences with older adults also predicted a greater willingness to pursue a future career in an aging-related field ($\beta = .333, p < .001$). Findings suggest that colleges could increase students' interest in pursuing aging-related careers with multiple interventions, such as developing opportunities to interact and build relationships with older adults in the community, updating information on job opportunities, pay scales, and advancement opportunities, and providing more gerontological course or modules.

'WE HAD MORE IN COMMON THAN I THOUGHT': SCAMMING AS AN UNDERGRADUATE SERVICE LEARNING TOPIC INVOLVING OLDER ADULTS

Marjorie Getz, *Methodist College, Peoria, Illinois, United States*

An ongoing activity that cuts across several courses in the Gerontology Certificate Program at our College is the completion of implicit association exercises focused on age. Most college students show a distinct preference for those who are younger adults. It is difficult to get across to these students that the construct of being an adult is appropriate for all people beyond adolescence without relevance to age. College students enrolled in healthcare programs often have distorted views of aging and may not fully appreciate that all adults may share common aspects of their current lives. We describe qualitative analyses of reflections taken from an undergraduate psychology course that included a service learning component involving older adult learners. The service learning lessons focused on victimization associated with fraud and scamming. The classroom structure involved round table discussions with direct contact between college students, older adults and local law enforcement personnel. Reflective practices were used to integrate course content (development in adulthood) into this service learning activity. We report on qualitative data taken from student reflections. Content analyses of reflective essays identified five themes which operated to produce stronger identification between age groups: frequency of being scammed across all 21 participants; insight that learning continues across the lifespan; understanding that broad learning challenges impact people

(for different reasons) at both ends of the adult age spectrum; respect for adoption of strategies that facilitate learning/compensate for cognitive changes that occur with aging; acknowledgement that familiarity breaks down barriers between people.

WHAT DO INTRODUCTION TO PSYCHOLOGY TEXTBOOKS HAVE TO SAY ABOUT OLDER ADULTS?

Zoe Hancock,¹ Matthew Wynn,² and Brian Carpenter,¹ 1. *Washington University in St. Louis, Saint Louis, Missouri, United States*, 2. *Washington University in St. Louis, Washington University in St. Louis, Missouri, United States*

Introduction to Psychology is one of the most popular undergraduate courses, an entry course for psychology majors and also popular with students from other disciplines. Consequently, the content in introductory psychology textbooks has the potential to influence undergraduates' knowledge, attitudes, and interests, including those related to aging. The purpose of this study was to analyze aging-related content in introductory psychology textbooks to understand the topics to which students are exposed in this important course. We analyzed the indices of 21 best-selling Introduction to Psychology textbooks for both advanced and intermediate audiences, published between 2018 and 2020. We extracted and aggregated 275 unique, aging-specific index terms from the textbooks and analyzed their relative frequency. We identified 61 superordinate index terms corresponding to general terms (e.g., "aging," "death"). The indices also included 214 unique subordinate terms that were more specific (e.g., "aging, and cognition"). Across textbooks, the most frequent topics reflected negative consequences of aging (e.g., "Alzheimer disease" = appeared in 100% of textbooks, "death" in 52%). In contrast, positive aspects of aging appeared less often (e.g., "generativity" in 47%, "longevity" in 10%). Terms describing career opportunities were rare (e.g., "gerontology" in 5%, "geropsychology" in 5%), as were modern theories (e.g., "socioemotional selectivity theory" in 28%). Advocacy for comprehensive and balanced representation of aging in introductory psychology textbooks is critical for educating students and promoting interest in the field.

Session 9210 (Poster)

Education and Training

A MASSIVE OPEN ONLINE COURSE TO EDUCATE HEALTHCARE PROFESSIONALS & CAREGIVERS ABOUT ALZHEIMER'S DISEASE

Mary DiBartolo, *Salisbury University, Salisbury, Maryland, United States*

Over 6 million Americans and 50 million persons worldwide are estimated to have Alzheimer's disease (AD) as it remains the major cause of dementia in the older adult population. Both healthcare professionals and family caregivers struggle with the complexities of caring for individuals with this progressive neurological disease. To address the ongoing knowledge and care gap regarding Alzheimer's disease among both healthcare professionals and family caregivers, a comprehensive massive open online course (MOOC)

was developed and made available via the edX platform. MOOCs are open access and interactive courses offered via the web; they have emerged as a popular, self-paced mode of distance learning. Launched in 2020, the MOOC titled, Alzheimer's Disease & Dementia Care, consists of five modules reviewing symptoms, diagnosis, medications, communication and care tips, as well as a module outlining special considerations when the person with AD is hospitalized. While this educational strategy targets healthcare professionals (such as nurses, physical therapists and related practitioners), it is also designed for lay caregivers or anyone who wants to learn more the disease. The course utilizes a variety of teaching modalities and is free. To date over 7000 persons have enrolled from over 140 countries. MOOCs remain an innovative and engaging educational strategy to reach a global audience. More importantly, they can serve as an another outlet to enhance both the competence and confidence of both healthcare professionals and family caregivers by sharing best practices in caring for those with Alzheimer's disease and related dementias.

IN THE EYE OF THE BEHOLDER: USING PHOTOGRAPHY TO TEACH GERONTOLOGY

Kristina Hash,¹ Matthias Naleppa,² and Anissa Rogers,³ 1. *West Virginia University, Morgantown, West Virginia, United States*, 2. *Radford University, Radford, Virginia, United States*, 3. *CSUSB, Palm Desert, California, United States*

Due to the widespread access to smart phones and similar technology, photography and photographic images have become an ever-present part of contemporary social life. Photographic methods are also growing in their use in higher education pedagogy. As a specific application, photography can be a powerful tool to educate students about aging processes and issues that impact older adults. This poster will explore the use of photographic methods and tools to teach and integrate aging-related concepts into gerontology and social work courses, at both undergraduate and graduate levels. Specifically, the use of digital storytelling, photo mapping, photo voice, and photo therapy will be highlighted. Descriptions of and consideration for assignments along with example student projects will be displayed and discussed as will other potential projects and uses of photographic methods. Attention will be paid to how photographic methods can help students explore the diversity and intersection of individual characteristics and experiences with the aging process and how intersectional identities can influence, and be influenced by, aging and external factors and processes.

MOVING TOWARD AN AGE-FRIENDLY UNIVERSITY: SURVEY PROCESS OF GSU 50+ STUDENTS

Grace da Rosa,¹ Jacqueline Laures-Gore,² Sarah Barber,³ Mariam Qureshi,³ and Elisabeth Burgess,³ 1. *Georgia State University, Suwanee, Georgia, United States*, 2. *Georgia State University, Georgia State University, Georgia, United States*, 3. *Georgia State University, Georgia State University - Atlanta, Georgia, United States*

The proportion of Georgia's population that is 60 years and older is growing rapidly. The 2010 U.S. Census Bureau predicted a growth of more than 20% of older adults by the year 2030. Georgia residents who are 62 and older are

eligible to take courses at no or little cost at public state colleges. Due to the expected increase in Georgia's aging population, access to a free university education, and the large number of currently enrolled 62+ students at Georgia State University (GSU), it is crucial that GSU become an Age-Friendly University. During Fall 2019, a survey was distributed to 1046 students aged 50 years plus; 411 completed the survey (39% response rate). This presentation describes the process involved in designing and distributing the survey. Unique aspects of the survey's development include the cross-generational and interdisciplinary contributions of the student, faculty, affiliates, and staff from GSU's Gerontology Institute. The goal was to learn more about GSU students 50 years and older by assessing their motivation for attending school, challenges on campus, perceptions of how the university is currently addressing their needs, factors/resources that have helped/are helping them to adjust to school, and the extent to which they experience age discrimination on campus. The long-term goal of the survey is to use this information to direct GSU in becoming an Age-Friendly University.

NOW WHAT? MAINTAINING MOMENTUM AFTER ACHIEVING DESIGNATION AS AN AGE-FRIENDLY UNIVERSITY

Diane Martin,¹ Nicole Brandt,² Denise Orwig,³ Barbara Resnick,⁴ Daniel Mansour,⁵ Elizabeth Galik,⁶ John Schumacher,⁷ and Meredith Upton,³ 1. *Geriatrics & Gerontology Education and Research Program, University of Maryland, Baltimore, Baltimore, Maryland, United States*, 2. *University of Maryland School of Pharmacy, University of Maryland School of Pharmacy, Maryland, United States*, 3. *University of Maryland, Baltimore, Baltimore, Maryland, United States*, 4. *University of Maryland, Baltimore, Maryland, United States*, 5. *University of Maryland School of Pharmacy, Baltimore, Maryland, United States*, 6. *University of Maryland School of Nursing, Baltimore, Maryland, United States*, 7. *University of Maryland, Baltimore County, Baltimore, Maryland, United States*

The Age-Friendly University (AFU) designation in higher education recognizes the institution's commitment to a culture of age-inclusivity across programs and policies. While AFU institutions are embracing the demographic shifts in higher education and society at-large, effectively responding to the needs and desires of an increasingly older population requires ongoing acceptance and support from campus leaders to maintain momentum and stay relevant within a dynamic field. This session will describe the intentional and systematic approach utilized by an AFU steering committee to build interest in and develop meaningful collaborations in multiple domains across campus, including at the level of the president. Our initiatives focus on five themes that align with the 10 age-friendly university principles: support for workforce development, broadening community engagement, expanding engagement in aging research and dissemination, addressing barriers related to aging and our physical environment, and facilitating age-friendly efforts across our state. We will present our experiences in expanding awareness of and support for the AFU movement on our campus and share a model for institutions seeking ideas for sustainability of their own initiatives.

SIMULATING TREATING IN PLACE IN LONG-TERM CARE: INTERPROFESSIONAL TEAM CARE VIDEO CASE FOR NURSE PRACTITIONERS

Laurie Kennedy-Malone, *UNCG School of Nursing, Greensboro, North Carolina, United States*

As a means of enhancing clinical simulation opportunities for adult-gerontology nurse practitioner students, a series of video simulations were created for use for nurse practitioner education. With funding through the Health Resources and Service Administration (HRSA) Advanced Nursing Education Workforce grant and partnering with nurse practitioner clinical educators from Optum Health Care, a video simulation focused on the concept of treating an older veteran within a long-term care facility rather than transferring to the acute care setting was developed. The case *Treating in Place: Nurse Practitioner-Led Team Management of a Long-Term Care Patient Video* involved a nurse practitioner collaborating with a physician, a registered nurse, a social worker, and a family member. The interactive simulation video was developed using the eLearning authoring tool H5P to create learning experiences for students that can be used either in face-to-face classroom experiences or embedded in learning management systems. H5P is a web-based authoring tool that helps faculty build interactive course content. H5P activities provide instant feedback to students, allowing them to self-assess their understanding of the dynamic video simulation case. A faculty handbook that describes the case scenario with the interactive questions and suggested discussion questions is available. The adult-gerontology primary care nurse practitioner competencies addressed for this case are identified in the faculty handbook. These videos have been widely disseminated and are being included in nurse practitioner curriculum across the country. A QR code with access to direct viewing of the video will be included in the presentation.

STARTS AND STOPS: STRATEGIZING AN AGE-FRIENDLY UNIVERSITY COMMITMENT DURING A PANDEMIC

Paige Ebner,¹ Kenneth Ferraro,¹ Brian Pastor,² and Wendy Rogers,² 1. *Purdue University, West Lafayette, Indiana, United States*, 2. *University of Illinois Urbana-Champaign, Champaign, Illinois, United States*

The Global Network of Age-Friendly Universities seeks to enhance age-inclusivity and engagement in higher education, but delivering age-friendly programming became very challenging during the COVID-19 pandemic. We examine how two land-grant universities adapted to the pandemic and draw some lessons from those experiences that may be useful for other universities seeking to implement or resume the AFU programming. The two main responses were to either pause many of the age-friendly initiatives at the university or adapt to virtual or online delivery platforms. To ensure the health and safety of older adults, colleges and universities paused many age-friendly initiatives such as intergenerational service-learning, technological assistance to older adults, and influenza vaccinations. Other programs continued but in a modified delivery format. Examples include: converting a face-to-face balance-training program to telehealth delivery; transitioning visitation programs to pen pal communication; and replacing face-to-face workshops offered by Extension

Services with webinar delivery. Despite these challenges, we conclude that moving to virtual platforms and other methods of delivery, including conventional mail, has in some cases increased access for many older adults and became a lifeline during a time of social isolation for many older adults. Taken together, these experiences highlight the need for age-friendly universities to have contingency plans to ensure continuation of age-friendly programming in the event of pandemics or disasters. Finally, the pause in programming creates opportunities to re-launch or re-organize those initiatives in accord with federal and state safety guidelines.

TEACHING IN GERIATRICS: IS STRUCTURED WRITTEN FEEDBACK EFFECTIVE FOR LECTURES

Theresa Pohlmann,¹ Klaus Hager,² Volker Paulmann,¹ and Sandra Steffens,¹ 1. *Medical School Hannover, Hannover, Niedersachsen, Germany*, 2. *Medical School of Hanover, Hannover, Niedersachsen, Germany*

Background: Although there have been discussions about traditional lecturing, lectures are still largely a widespread concept of knowledge transfer. Therefore, it is important to constantly review and evaluate this format. The aims of this study were to analyze which effect a criteria-based written feedback has on the lecture course in geriatrics as an alternative to the conventional student evaluation. Furthermore, we wanted to investigate what kind of impact structured feedback has on lecturers in terms of content, organization and quality. **Methods:** The study was a prospective longitudinal analysis. The 34 lectures on the subject of geriatrics were analyzed over two cohorts using a standardized evaluation sheet. The assessment was carried out on a 5-point-scale using a 22-item feedback instrument. After the first evaluation, each lecturer received an individual evaluation with strengths and suggestions for improvement. In the second cohort the lecture series was evaluated again, and individual feedback was sent. **Results:** In six of 22 sub-categories the improvement was significant. The most significant improvement was made in terms of content/structure with an increase from 3.4 to 4.3 points. **Conclusion:** This study shows that significant improvement in teaching is possible by means of individualized written feedback for the lecturers and that students perceive the resulting improvements positively. Our results suggest that the implementation of these feedback instruments in other modules might improve their teaching as well.

THE 4MS PROVIDE A STRUCTURAL FRAMEWORK FOR ORGANIZING EDUCATIONAL MATERIALS

Edmund Duthie,¹ Deborah Simpson,² Amanda Szymkowski,³ Kathryn Denson,³ and Steven Denson,³ 1. *Medical College of Wisconsin, Milwaukee, Wisconsin, United States*, 2. *Advocate Aurora Health, Advocate Aurora Health/Milwaukee, Wisconsin, United States*, 3. *Medical College of Wisconsin, Medical College of Wisconsin/Milwaukee, Wisconsin, United States*

The John A Hartford Foundation and the Institute for Healthcare Improvement (IHI)'s 4Ms of mentation, mobility, medications and (what) matters most provide a much-needed framework for helping system leaders and frontline teams consistently deliver high-quality, age-friendly care. Geriatric Fast Facts (GFFs) is a virtual resource providing teachers/

learners with peer-reviewed, evidence-based summaries on topics essential to older adult care via a searchable website [www.geriatricfastfacts.com]. To determine if GFFs can be classified by the 4Ms we initially did a free text search of all GFFs. That revealed GFFs whose foci were unrelated to the 4Ms (e.g., mobility emerged in a fluoroscopy GFF as a minor element related to patient positioning). Therefore, all GFFs were independently reviewed by a geriatrician and the website manager and classified according to the 4M rubric (a single GFF can be classified in multiple M's such as #93 on Age Friendly Health Systems). Any differences were adjudicated by the GFF editor. 64% (60/ 93) of GFFs strongly linked to one of the 4Ms. The number of GFFs dedicated to the 4Ms are as follows: 20 what matters most, 18 medications, 13 mentation, and 9 mobility. Those that were not coded within 4Ms were often very disease/specialty oriented. A total of 36 were not classified. For example, GGF #39 focuses on the etiologies of anemia among older adults. The 4M framework can be easily applied to educational materials to support consistent and clear conceptual model across learning conditions and materials.

WHAT DO UNDERGRADUATES LEARN ABOUT ALZHEIMER DISEASE? AN ANALYSIS OF INTRODUCTION TO PSYCHOLOGY TEXTBOOKS

Zoe Hancock,¹ Matthew Wynn,² and Brian Carpenter,¹ 1. *Washington University in St. Louis, Saint Louis, Missouri, United States*, 2. *Washington University in St. Louis, Washington University in St. Louis, Missouri, United States*

One of the most popular courses for undergraduate students, Introduction to Psychology, is often students' first exposure to scientific and clinical facts about Alzheimer disease (AD). In order to learn how our current understanding of AD is presented to undergraduate psychology students, we analyzed passages related to Alzheimer disease that appear in contemporary Introduction to Psychology textbooks. We extracted and analyzed passages describing AD from twenty-four best-selling Introduction to Psychology textbooks for both advanced and intermediate undergraduate audiences, published between 2018 and 2020. We applied a standardized coding scheme to the passages to quantify what aspects of AD were most commonly described. Each textbook contained between 1 and 3 major passages regarding AD, most often appearing in the chapters on Memory or Human Development. Average word count for these passages was 409.1 words (SD = 194.8 words). Passages most often covered biological aspects of AD (87.5% of textbooks), symptoms (87.5%), prevalence (75%), and risk factors (75%). Disease prevention (62.5%) and illness course (62.5%) also appeared in the majority of textbooks, while aspects of treatment and management (25%), assessment and diagnosis (12.5%), and caregiving (25%) were mentioned less often. While the majority of books used contemporary and appropriate terminology to describe AD (e.g., "Alzheimer disease," "dementia," "neurocognitive disorder"), some textbooks maintained the use of out-of-date and inappropriate terminology (e.g., "senility" or "senile dementia" in 15%). Introductory psychology textbooks provide an opportunity to teach comprehensive, accurate information about AD and publishers and textbook authors could be guided in this effort.

Session 9215 (Poster)

Education and Training: Workforce Development

ADAPTING THE ENVIRONMENTAL SCAN FOR GERONTOLOGY GRADUATE STUDENTS' CAREER EXPLORATION

Nasreen Sadeq, and Brienne Stanback, *University of South Florida, Tampa, Florida, United States*

Environmental scanning is a process that provides organizations with information about their internal and external strengths, challenges, and opportunities. Although traditionally used in business and strategic planning, environmental scanning is now being utilized in health care to evaluate currently available programs and services, identify gaps in patient care or research, and make educational, organizational, and policy recommendations. The current study explores adapting the environmental scan for students enrolled in a gerontology graduate program as a tool to facilitate career exploration. Students learned about environmental scanning and were instructed to perform an environmental scan on an important issue, program, or service relevant to their overall career goals. Because students completed their environmental scan while enrolled in an Alzheimer's Disease Management course, they were encouraged to factor in the increasing prevalence of Alzheimer's disease into their project. Students' environmental scan projects spanned several timely topics, including an evaluation of the services currently offered in assisted living facilities from the perspective of a geriatric social worker, a review of memory training interventions and a proposal for a new research study, and preliminary plans for opening an assisted living facility catering to older adults in the LGBTQ community that outlined financial considerations, staff training goals, and patient care plans. Completing the environmental scan project gave students an opportunity to investigate the current state of the career field they are planning to enter, and provided them with a product that they can build upon as they complete the graduate program and begin their careers.

ALTERNATIVE PATHWAYS: THE USE OF FIELD-SPECIFIC MICRO-CREDENTIALS IN AGING SERVICES

M. Aaron Guest,¹ Leanne Clark-Shirley,² Cynthia Hancock,³ Tina K. Newsham,⁴ Katherine Alvarado,³

Kristina Amirchian Renee DuMont,⁵ Lauren Hackett,⁵ Kaylah Jenkins J.R. Patton,⁵ and Caylee Weaver *1. Arizona State University, Tempe, Arizona, United States, 2. American Society on Aging, American Society on Aging, California, United States, 3. University of North Carolina Charlotte, Charlotte, North Carolina, United States, 4. University of North Carolina Wilmington, University of North Carolina Wilmington, North Carolina, United States, 5. University of North Carolina Wilmington, Wilmington, North Carolina, United States*

The rise of formal academic programs in gerontology at colleges and universities has been well documented over the last fifty years. Organizations such as AGHE and AGEC have been established to provide guidance, foster consistency, and advance formal gerontology education programs. Broadly, the purpose of these programs has been to develop

a pipeline of trained gerontologists for the aging services workforce. What has been less documented is the rise of alternative pathways to gerontology and gerontological competence, including micro-credentialing. Micro-credentials are intended to provide quick-to-complete competency-based education around specific topics to demonstrate relevant skills to employers. To date, little is known about the prevalence of micro-credentialing in gerontology. Still, it may be that micro-credentials are sought in place of formal academic preparation due to their reduced cost, ease of completion, recognizability, and opportunity to quickly train employees in specific skills. To address this gap, we conducted a review of existing gerontological micro-credentialing opportunities. We identified a total of 51 micro-credentials with an explicit aging-focus and searched for associated competencies for these micro-credentials. In this poster, we describe findings on the emphases of micro-credentials, including dementia and care coordination, and review the programs' scope and nature of competencies. We argue that micro-credentialing can offer value for employees unable or unwilling to pursue formal academic training but should be differentiated from such training. Moving forward, it is critical to ensure alignment between gerontological micro-credentials and established gerontological competencies and standards and to differentiate micro-credentials from formal academic programs.

AN 18-YEAR EXPERIENCE WITH AN INNOVATIVE GERIATRICS TRAINING MODEL: IMPLICATIONS FOR THE WORKFORCE

Cara O'Brien,¹ Evan Henricks,² Angela Beckert,² Kathryn Denson,³ and Edmund Duthie,² *1. Medical College of Wisconsin, Wauwatosa, Wisconsin, United States, 2. Medical College of Wisconsin, Milwaukee, Wisconsin, United States, 3. Medical College of Wisconsin, Medical College of Wisconsin/Milwaukee, Wisconsin, United States*

Despite the growing population of older adults, the geriatrics workforce has not similarly expanded. The number of geriatrics fellows has declined by 14.3% from 2012-2017. Implementation of innovative training programs may improve this reality. In 2002, the Medical College of Wisconsin (MCW) created the first four-year combined medicine residency and geriatrics fellowship (Med-Ger). Similar programs are currently being developed. The aim of this study is to describe the outcomes of the MCW Med-Ger program. Primary endpoints: American Board of Internal Medicine (ABIM) pass rates, ABIM Geriatric Medicine Certification pass rates, fellowship completion rates, and geriatric-focused practice. Results: There was a Med-Ger program fill rate of 73.7% (n=38). There was equivalent ABIM pass rate of 100% between Med-Ger graduates (n=18) and traditional graduates (n=25). Med-Ger trainees were more likely to complete their geriatrics fellowship (94.4% vs. 88%) and practice in geriatric-focused careers (82.4% vs. 68.2%). These outcomes suggest the benefit of a combined program for training future geriatricians. The MCW Med-Ger fill rate exceeds the national geriatrics fellowship fill rate of under 50%. Additionally, graduates may be more likely to practice geriatric medicine. This may help address population needs for an increased geriatrics workforce. In 2020, the ACGME approved an Advancing Innovation in Residency

Education (AIRE) Medicine-Geriatrics Integrated Residency and Fellowship national pilot program. Further investigation of why trainees choose Med-Ger training and are more likely to continue with careers in geriatrics is needed in order to replicate the success of the MCW Med-Ger program.

AN INTER-UNIVERSITY VIRTUAL GERIATRIC CASE COMPETITION TO BUILD INTERPROFESSIONAL COLLABORATION SKILLS

Kristine Talley,¹ Marla Berg-Weger,² Devita Stallings,³ Teresa Schicker,¹ Laura Pesja,¹ and Jean Wyman,¹ 1. *University of Minnesota, Minneapolis, Minnesota, United States*, 2. *Saint Louis University, Saint Louis, Missouri, United States*, 3. *Saint Louis University, St. Louis, Missouri, United States*

Developing positive learning experiences in team-based geriatric care is challenging. This presentation will highlight an inter-University geriatric case competition for developing interprofessional competencies in health professional students sponsored by the Geriatric Workforce Enhancement Programs at Saint Louis University and the University of Minnesota. The virtual competition involved teams of 4-5 undergraduate and graduate students from multiple health professions who designed a comprehensive care plan using a simulated complex geriatric patient case. Students were assigned to an interprofessional team with a faculty or community expert coach, attended an orientation, and developed a 20-minute recorded presentation. A panel of judges rated team presentations using a scoring rubric based on the Core Competencies for Interprofessional Collaborative Practice. Local competitions included a first and semi-final round, with the winning teams presenting at the inter-university competition held via live videoconferencing that involved a question-and-answer session. Prizes were given to the top teams. Students, coaches, and judges completed evaluation surveys focused on satisfaction with the competition format/procedures and achievement of interprofessional competencies. Twenty-one teams and 117 students from 12 disciplines participated. Team scores ranged from 2.2 to 4.3 (overall mean 3.1) on a 1-5 scale. Judge, coach, and student evaluations were positive, indicating students learned valuable lessons in group dynamics, team-based care, and geriatric care. Most students (82%) preferred the virtual competition format or had no preference on format. The virtual case competition provided a positive, engaging experience to introduce health professional students to geriatric team-based care and develop their readiness for collaborative practice.

ART AND AGING: USE OF SOCIAL MEDIA FOR GERIATRIC EDUCATION

Gunjan Manocha, Casey Morton, Nicole Derenne, Heidi Bau, and Donald Jurivich, *University of North Dakota, Grand Forks, North Dakota, United States*

Social media as an educational tool for health care learning has untapped potential. Benefits of social media include peer-to-peer engagement, active learning and interprofessional training. Here we explored social media platforms as a vehicle to deliver short, pithy clinical pearls from evidence-based, peer-reviewed manuscripts. Key points from recent medical publications are paired with pre-existing artwork to provide visual reinforcement of the clinical pearl. Dubbed

“Art and Aging”, the clinical pearl and artwork combination is posted on different social media platforms such as Instagram, Twitter and Facebook, thus allowing for an expansive audience. Different hashtags and tags are used to increase followers and engagement on each platform. Over a 9 months period learner engagement increased by 150% and includes a diverse learner profile. These curated social media platforms show considerable promise for disseminating Geriatrics best practices. As yet, we do not know subject matter retention or whether it changes clinical practices - both questions which are future research objectives.

EXPERIENTIAL SERVICE LEARNING: PROMOTING COMPETENCY-BASED EDUCATION FOR GERONTOLOGY STUDENTS

Theresa Abah and Linda Paumer, *California State University, Sacramento, Sacramento State University, California, United States*

Service-learning is an effective pedagogical approach meant to deepen learners understanding of course content by linking scholarship and social action when structurally organized based on attainment of professional core competencies. The recent COVID-19 pandemic caused a rethinking of the way service learning practicum is delivered, especially as it relates to training health professionals who engage collaboratively with older persons (individuals aged 65 years and older). This poster examines the challenges faced by gerontology students as they transitioned to fully virtual learning and practicum format, the lessons learned, and how to close the gap between theory and practice for better programmatic processes. The data used to gather students experiences include; student reflective journals, class discussions and survey questions to students (n=44). The analytic framework utilized is the Social Cognitive Theory, (SCT)- which explains how individuals can master concepts through verbal and physical persuasion, including peer modelling. The goal is to promote learners self-regulatory skills to achieve the course learning objectives, as obtained from the SCT six strategies for setting achievable goals, through: Feedback, self-instruction, self-monitoring, use of support and goal setting. Some of the lessons learned suggest students benefit more from service learning when they receive continuous feedback about how to develop intergenerational relationships with older adult partners assigned to in the community (68%), than from goal setting strategies (24%). The implication for practice is: there is a need to develop structured service-learning guidelines for undergraduate students in gerontology program to be prepared to better serve older adults.

GERIPOP: OLDER ADULTS POPULATION HEALTH SERIOUS GAME

Gunjan Manocha,¹ Casey Morton,¹ Jeremy Holloway,¹ Scott Brewster,² Joseph Wood,¹ Richard Van Eck,¹ and Donald Jurivich,¹ 1. *University of North Dakota, Grand Forks, North Dakota, United States*, 2. *Triad Interactive Media, Brooklyn, New York, United States*

Health professionals have limited opportunities to learn about population health in their curriculum. With a shortage of geriatricians nationwide, health care systems need different ways to provide evidence-based geriatric care. To address both these shortcomings, a serious game, called

GeriPOP has been developed to allow trainees to explore the impact of assessment and management of principles of geriatric care (the 4Ms+) on quality of life, health, longevity, and health care costs by applying them to a virtual older adult population. Trainees assume the role of a system manager who is asked to explore ways to optimize health outcomes and lower costs. They develop their population health plan around a framework of Geriatric 4Ms+ and apply it in a virtual panel of older adult patients that move longitudinally into different age bands (65-74; 75-84; 85+). As the game progresses, a dashboard helps trainees track the impact of their treatment decisions across the population. Several levels of play allow trainees to explore various issues intersecting with aging such as gender, diversity, social determinants, and multiple chronic conditions. Periodic debriefings and explanatory pop ups during the game allow trainees to further explore evidence-based Geriatrics. The game engages health care trainees to strengthen their knowledge of Geriatrics through exploration of systems change. Future study is needed on whether Geri POP changes learner attitudes, future clinical practice or healthcare outcomes.

IMPACT OF VIRTUAL REALITY ON HEALTHCARE PROVIDER EMPATHY FOR OLDER ADULTS WITH SENSORY IMPAIRMENT

Suzanne Dutton,¹ and Andrea Cimino,² 1. *Sibley Memorial Hospital/Johns Hopkins, Washington, District of Columbia, United States*, 2. *Danger Assessment Training and Technical Assistance Center, Johns Hopkins School of Nursing, Baltimore, Maryland, United States*

Virtual reality (VR) is an innovative technology that can simulate dual sensory impairment so that healthcare providers can experience this affliction common in older adults. The current study investigated whether VR simulation could increase empathy among healthcare workers. Empathetic care is linked with improved patient satisfaction, compliance, and outcomes. The study used a one-group pre/posttest study design implemented with healthcare providers at a hospital in the Mid-Atlantic region. All participants experienced a 7-minute VR scenario from the viewpoint of “Alfred”, a 74-year-old with macular degeneration and high frequency hearing loss on a commercial VR headset (Oculus Rift). A survey assessed participants’ self-reported knowledge, empathy, and behavior change. Empathy was measured using the validated tool Kiersma-Chen Empathy Scale (KCES). Analyses included descriptive statistics and paired t-tests. Survey results showed that participants increased their knowledge of macular degeneration and hearing loss, and that 9 of 14 empathy items had statistically significant increases (average absolute change = .41 points). Additionally, 97% of participants agreed or strongly agreed that they would utilize the information learned in their work with patients. Evidence suggests VR is an effective intervention to increase empathy and positively change behavior to support persons with sensory impairment.

OLDER ADULTS' PERCEPTIONS OF COLLEGE CAMPUS ACCESSIBILITY

Ashley Ermer, and Nadine Verna, *Montclair State University, Montclair, New Jersey, United States*

The emerging Age-Friendly University Global Network encourages universities to engage older adults in university

activities (Gerontological Society of America, 2019). As such, attention should be devoted to the accessibility of campus facilities to older adults as a potential mechanism to increase age diversity. Intergenerational interactions, which may take place on college campuses, promote better perceptions of other generations (Bertram et al., 2017), making campus accessibility for all age groups a priority. The present study sought to uncover older adults’ perceptions of campus accessibility via an online survey. Participants were recruited through local newsletters, word of mouth, and included 81 community members (Age mean=71.58 years; 79% female; 89% White; 43% traveled to campus every few months). Descriptive analyses were conducted for closed-ended responses and two members of the research team used a constant comparative method (Corbin & Strauss, 2015) to code open-ended responses. Participants felt that campus was somewhat accessible (M = 2.72; 1(very inaccessible) to 5(very accessible)), moderately easy to walk around (M=3.79; 1(extremely difficult) to 7(extremely easy)), and felt somewhat welcome on campus (M=3.27; 1(strongly disagree) to 7(strongly agree)). The following general themes emerged in the open-ended responses: 1)inaccessibility on campus was due to parking, drop-off locations, and topography (e.g., due to stairs, distance, hills) constraints; 2)feeling welcome on campus was due to people being helpful; and 3) difficulty in attending events was due to parking and lack of knowledge about events. Implications for campus initiatives that aim to attract older adults, especially for campuses that have topography constraints, will be discussed.

SHINING A LIGHT INSIDE THE “BLACK BOX” OF NIH APPLICATION SUBMISSION AND REVIEW

Elia Ortenberg,¹ and Shalanda Bynum,² 1. *National Institutes of Health, Bethesda, Maryland, United States*, 2. *Center for Scientific Review (CSR) National Institutes of Health (NIH), Bethesda, Maryland, United States*

What happens to applications after they are submitted to the National Institutes of Health, and how can you better prepare yourself and your application for the process of peer review? The Center for Scientific Review (CSR) works closely with the 24 funding institutes and centers at the National Institutes of Health that provide funding support for projects of high scientific merit and high potential impact. CSR conducts the first level of review for the majority of grant applications submitted to the NIH, which includes 90% of R01s, 85% of Fellowships, and 95% of Small Business Innovation Research (SBIR) applications as well as many other research and training opportunity activities. In this capacity, CSR helps to identify the most meritorious projects, cutting-edge research, and future scientists who will advance the mission of the NIH: to enhance health, lengthen life, and reduce illness and disability. The purpose of this project is to provide an overview of 1) what happens to NIH applications before, during, and after peer review at CSR; 2) a summary of new and current peer review policies and practices that impact investigators and their submitted applications; and 3) strategies for developing a strong NIH grant application. Peer review is the cornerstone of the NIH grant supporting process, and an insider’s view can shine a light inside the “Black Box” of how the most meritorious projects are identified.

STRENGTHENING COLLABORATIONS FOR GERIATRICS KNOWLEDGE: TWITTER JOURNAL CLUB FOR GERIATRIC FELLOWS

Gunjan Manocha,¹ Casey Morton,¹ Elizabeth Chapman,² Daniel Pellecer,³ Kahli Zeitlow,⁴ Tanjeev Kaur,⁵ and Donald Jurivich,¹ 1. *University of North Dakota, Grand Forks, North Dakota, United States*, 2. *University of Wisconsin, Madison, Wisconsin, United States*, 3. *Mayo Clinic, Rochester, Minnesota, United States*, 4. *Michigan Medicine, Ann Arbor, Michigan, United States*, 5. *University of Illinois at Chicago, Chicago, Illinois, United States*

The pandemic has challenged training programs in numerous ways, specifically in the ability to conduct group based teaching sessions. To overcome this challenge Twitter was examined as a vehicle for engaging Geriatric Fellows in education about critical appraisal of clinical research. A secondary objective was to develop educational synergy among university-based programs. To achieve these aims, 5 Midwestern Geriatric and Palliative Medicine Fellowship programs agreed to enroll their fellows into a monthly Geriatrics Twitter Journal Club, that commences on Twitter Tuesday and lasts a week. Each month, an assigned fellow selects an article to discuss and creates a short video to introduce it. A Twitter master delivers structured questions to guide fellows' collective input on the article being critiqued. Over a 3 month roll out of @GeriatricJC, the twitter account of the journal club has gained 144 followers that includes 20 fellows, 63 geriatricians/geriatric faculty, 28 organizational accounts, 5 students and around 28 other providers and experts. From December 2020- February 2021, account generated tweets resulted in an average of 397 impressions/day with 2548 visits to the account profile per month. Videos posted have averaged 73 views/video. Discussion in journal club using #GeriJC has garnered 178 tweets from participants. This project shows that Twitter is a feasible platform for a fellowship journal club among several training programs, thus expanding expertise in evidence-based medicine while lowering the administrative burden of preparing journal club within a single program and increasing both faculty and trainee convenience of learning.

TO CLARIFY THE DURATION AND CHARACTERISTICS OF THE CONTINUATION OF HOME CARE FOR OLDER PEOPLE WITH DEMENTIA

Reiko Kanaya,¹ Asuka Oyama,² Hiroshi Toki,³ Ryohei Yamamoto,⁴ and Miyae Yamakawa,¹ 1. *Osaka University Graduate School of Medicine, Suita City, Osaka, Japan*, 2. *Health and Counseling Center, Osaka University, Suita City, Osaka, Japan*, 3. *Osaka University Health and Counseling Center, Suita City, Osaka, Japan*, 4. *Osaka University, Suita City, Osaka, Japan*

As populations age worldwide, older people with dementia are increasing. Caregivers are also aging, necessitating arrangements like social services. How to prolong the home care desired by older people remains unclear. Using data from the Osaka National Health Insurance Database from 2012 to 2017 on insured persons' registers, medical notes, and care benefits, this study included 9591 people aged ≤ 74 years with first dementia drug prescription between April 2013 and December 2017. Using the prescription as baseline and hospitalization or nursing home admission as outcomes, home

care duration and characteristics of medical and nursing care services during the year before baseline were evaluated. Survival was compared by Kaplan–Meier curves and the log-rank test. Multivariate analysis was performed using the Cox proportional hazards model. During follow-up, the outcomes were observed in 1473 patients : 317 admission , 1145 hospitalized and 11 both. Mean duration of home care in patients with the outcomes was 11.5 months, which differed significantly from patients without these outcomes. When patients were grouped by hospitalization in year before first prescription, the survival curves differed significantly. In multivariate analysis, sex, renin-angiotensin system agonists, hyperlipidemia drugs, hospitalization history in past year, care level, and diabetes drugs were significantly associated with the outcomes. Taken together, hospitalization history, female sex, and diabetes were associated with home care disruption. Those undergoing cardiovascular disease treatment continued to live at home. For people with dementia, it is important to intervene by focusing on past medical and nursing care to continue life at home.

Session 9220 (Poster)

Education and Training-Program Evaluation-Workforce Development

A STUDY ON TRENDS IN THE NUMBER AND CONTENT OF JOURNAL ARTICLE TITLES CONTAINING THE TERM “ELDER ABUSE”

Asako Katsumata,¹ and Noriko Tsukada,² 1. *Rehabilitation Institution, Chiba, Chiba, Japan*, 2. *Nihon University, Tokyo, Tokyo, Japan*

Japan enacted the Elder Abuse Prevention Law on April 1, 2006; no amendments have been made since then. The purpose of this study is to examine trends in the number and content of journal article titles containing the term “elder abuse” and determine what further research is needed to identify where amendments to the law would be useful. We identified 986 articles using the CiNii database between the dates of 2005 to 2020. We categorized those titles by content, using a KJ Method. Preliminary analyses revealed that the average number of the articles published each year was 61.6, though a moving average of the numbers of articles on elder abuse has been steadily declining, as opposed to the average number for child abuse articles, 158, where the moving average staying the same. As for the analyses for the titles, they were categorized into 10 categories, including “law,” “responses of professional personnel to elder abuse,” “systems of government agencies,” “responses of nurses,” “institutional elder abuse,” “support for caregivers,” “reports on elder abuse in other countries,” “dementia and elder abuse,” “responses of medical institutions,” and “others.” It is suggested that more research needs to be done, especially in such areas as “verification of elder abuse cases,” “psychological impacts on elder abuse victims,” “empirical research conducted by medical doctors dealing with elder abuse cases,” and “cooperation between police and professional institutions,” many of which were found in research on child abuse where 4 law amendments have been made since its enactment of 2000.

AN ASSESSMENT OF DEMENTIA CAREGIVERS' INTERACTION WITH COMMUNITY-BASED SERVICES

Deepika Pugalenthi Saravanan,¹ Nihal Satyadev,² Natasha Townsend,³ Katherine Rose,⁴ Harrison Ma,⁵ Donna Benton,⁶ and Lené Levy-Storms,⁷ 1. *UCLA, San Ramon, California, United States*, 2. *The Youth Movement Against Alzheimer's, Los Angeles, California, United States*, 3. *Youth Movement Against Alzheimer's, Culver City, California, United States*, 4. *Youth Movement Against Alzheimer's, Los Angeles, California, United States*, 5. *University of Southern California, Los Angeles, California, United States*, 6. *University of Southern California Family Caregiver Support Center, Los Angeles, California, United States*, 7. *UCLA Luskin School of Public Affairs/Social Welfare, West Hills, California, United States*

Respite care is an important service to address caregivers' stress and fatigue when caring for a person with dementia (PWD). YouthCare is a non-medical, at-home, intergenerational respite care program that partners trained student volunteers with PWDs. The Family Caregiver Survey was created and distributed to caregivers of PWDs in Los Angeles to better understand interactions with the community and its caregiver services. The survey assesses caregivers' demographics, daily activities, mental health, and the type of respite support needed. The survey findings (n=47) show that 53.2% of caregivers are 54 and older and 83% females. 40.4% of the caregivers listened to the radio primarily in the morning while 61.7% watched television in the afternoon to evening time. For transportation of PWDs to and from destinations, 78.3% of caregivers reported using their own vehicles. In regards to their mental health, 61.7% of the caregivers stated that they felt tired and unmotivated to complete daily activities. When asked why they sought respite services, 40% stated that they were overwhelmed by the responsibilities in addition to their own work. The groups that primarily support caregivers are family and professional respite services. Findings indicate that caregivers are most likely to trust resource recommendations from family and friends. Similar surveys should be administered in other cities and in rural locations to improve the generalizability of our findings.

EARLY COLLABORATION MEASURES AMONG A CROSS-SECTOR STAKEHOLDER GROUP IN A STATEWIDE GWEP

Jennifer Crittenden,¹ Abigail Elwell,² David Wihry,² and Lenard Kaye,² 1. *University of Maine, University of Maine, Maine, United States*, 2. *University of Maine, Bangor, Maine, United States*

The AgingME Geriatrics Workforce Enhancement Program (GWEP) uses collaboration across institutions of higher education, community-based organizations, and healthcare entities to imbed transformational healthcare practice change across Maine, a primarily rural state. To explore the factors that influence cross-sector collaboration among a diverse array of partners, a baseline anonymous electronic survey was distributed to the newly formed project steering committee. The survey consisted of the Wilder Collaborative Factors Inventory, an established measure of 22 research-based collaboration factors along with four open response questions on process-level challenges and opportunities for

improvement. A total of eleven responses (N = 11) were received out of 20 Steering Committee members (55% response). Collaboration strengths noted in the assessment include unique purpose of statewide GWEP efforts (M = 4.41 out of 5 points), mutual trust among members (M = 4.32), favorable social and political environment (M = 4.27), and a history of collaboration among partners (M = 4.27). Lower scores were received on the multiple layers of participation (M = 3.45 out of 5 points), and ability to compromise factors (M = 3.45). Qualitative responses reinforced the need for a common understanding of the project's goals and outcomes early on in the collaboration. Barriers to collaboration included scheduling considerations and limited time and energy among partners due to heightened COVID-19 response efforts. Results elucidate: 1) Early collaboration strengths and needs of a newly formed statewide education collaborative; and 2) Strategic action steps and focal points informing early partnership among organizations engaged in interprofessional health education efforts.

IMPLEMENTING A COMMUNITY-BASED COLLABORATIVE PROJECT DURING THE COVID-19 PANDEMIC: A PROCESS EVALUATION

Brittney Pond,¹ Leslie Ross,² Jarmin Yeh,² Brooke Hollister,³ Tiffany Cheang,⁴ Susie Yu,⁵ and Corinne Eldridge,⁵ 1. *University of California, San Francisco, University of California, San Francisco, California, United States*, 2. *University of California, San Francisco, San Francisco, California, United States*, 3. *University of California, San Francisco, California, United States*, 4. *Alameda Alliance for Health, Alameda, California, United States*, 5. *Center for Caregiver Advancement, Los Angeles, California, United States*

In-Home Supportive Services (IHSS) caregivers are critical linchpins in our long-term care system, but little research exists to examine the strategies for enhancing their role working in the homes of persons living with dementia (PLWD). The aim of the IHSS+ Alzheimer's Disease and Related Dementias Training Project (IHSS+ ADRD Training Project) is to implement a competency-based dementia training program for 600 IHSS caregivers and their consumers; and evaluate the training program's impact on caregiving, long-term services and supports, and health systems. This project is a partnership between the University of California, San Francisco, Institute for Health & Aging; Center for Caregiver Advancement, a nonprofit organization founded by home care workers; and Alameda Alliance for Health, a non-profit managed care plan created by and for residents of Alameda County, California. The research design and funding of the project was established just prior to the COVID-19 pandemic. As the pandemic evolved, the IHSS+ ADRD Training Project underwent many revisions and pivoted to remote strategies to ensure progress could be made toward the aims. This poster describes a process evaluation of how various challenges were addressed and subsequent changes were made to the methodology. Using a community-based participatory research and program evaluation hybrid model, this project remained nimble, configuring an online dementia training program and evaluation methods that accommodated safety needs of community partners. Benefits and limitations of implementing the IHSS+ ADRD Training Project, using remote strategies, to ensure IHSS caregivers

and their consumers could continue receiving education and support, are highlighted.

OLDER MEN'S PARTICIPATION IN COGNITIVE TRAINING: A REVIEW.

Estela González,¹ Carmen Requena,² and PAULA ALVAREZ,¹ 1. *Universidad de León, León, Castilla y León, Spain*, 2. *Universidad de León, León, Castilla y León, Spain*

Background: Cognitive training for healthy older adults living in a community is an essential resource that allows them to live at home for as long as possible. Objective: The purpose of the review is to examine the degree of participation of males and females in longitudinal studies of cognitive training. Moreover, we want to identify if these studies include the gender variable in their analyzes or reflect on its importance. Method: This review considered longitudinal cognitive training studies were published in English and Spanish and conducted with healthy older adults living in a community. Results: The Advanced Cognitive Training for Independent and Vital Elderly (ACTIVE) study (in English) and the Memoria Mejor (MM) Longitudinal Study (in Spanish), both illustrate the trend of sex/gender treatment of the studies reviewed: a) high participation of older people seventy and more years b) recruiting stratified by age and sex; c) males are disproportionately underrepresented in cognitive training studies [24% - 14%]; d) the evaluation measures (baseline, follow-up, and final) and dropout data are provided but not stratified by age and sex/gender. Conclusions: Researchers demonstrate awareness about the impact of sex/gender differences but do not focus on it. Understanding sex/gender differences are necessary for understanding not only that these differences occur, but also why they occur; this will allow policies or intervention programs with approaches that are more equitable for both sexes/genders to be formulated.

SOCIAL TRUST, LITERACY, AND LIFELONG LEARNING: A COMPARISON OF THE U.S. AND NORDIC COUNTRIES

Samuel Van Vleet,¹ Phyllis Cummins,¹ and Abigail Helsing,² 1. *Miami University, Oxford, Ohio, United States*, 2. *Scripps Gerontology Center, Miami University, Oxford, Ohio, United States*

Societal social trust has been shown to be related to economic growth and equality. Low levels of social trust are especially consequential in aging societies and can result in low levels of social capital and greater inequality at older ages. Nordic countries are known for their greater social trust, access to education, economic productivity, and social equality. To better understand social trust promoters, we explored data from the 2012/2014 Program for the International Assessment of Adult Competencies (PIAAC) to examine relationships among social trust, basic skills (i.e., literacy), and non-formal education (NFE) participation for adults ages 45 to 65, in the U.S., Denmark, Finland, Norway, and Sweden. Additionally, through 19 key informant interviews and a review of the literature, we investigated the structure and availability of NFE across the five nations. As compared to the U.S., adults ages 45 - 65 in Nordic countries have higher

levels of social trust (all Nordic countries; $p < 0.001$), lower rates of poor literacy skills (Finland, Norway, and Sweden; $p < .001$), greater rates of participation in NFE (Denmark and Sweden; $p < 0.05$). Through the availability of NFE, such as folk high schools and learning circles in Nordic countries, adults can participate in NFE at little or no cost. Similar programs are not available in the U.S. This research informs policy and practice for the provision of NFE, which is critical to increase levels of social trust, and in turn, to promote economic development, social equality and positive aging in the U.S.

STRATEGIES FOR DEVELOPING AN INCLUSIVE GERIATRIC PHYSICIAN WORKFORCE FOR OLDER ADULTS IN THE U.S.

Brandy Wallace,¹ Leanne Clark-Shirley,² and Pallavi Podapati,³ 1. *University of Maryland, Baltimore County, Baltimore, Maryland, United States*, 2. *American Society on Aging, American Society on Aging, California, United States*, 3. *Princeton University, Princeton University, New Jersey, United States*

The “geriatric imperative” has been part of the aging discourse for more than 30 years but neither geriatric practice nor older adults are homogenous. As the U.S. population ages, elders will become more racially and ethnically diverse; and, their health outcomes will be shaped by lifetime experiences with systemic discrimination and racism. Already, COVID-19 has made clear that older adults and non-Whites, particularly African Americans and Hispanics, disproportionately bear the burden of disease and illness. Research suggests health disparities will continue unless there is change within the health care system. The Institute of Medicine (2001) reported on the problematic nature of the stark contrast between the diversity of patients and the physicians caring for them, including issues with patient trust and communication, yet no significant movement has been made to diversify the physician workforce. Despite being 13% and 16% of the U.S. population, respectively, African Americans and Hispanics make up just 5% and 6% of the practicing physician workforce. Further, practicing geriatricians represent less than 1% of physicians with very few physicians of color. There is a need for more African American and Hispanic geriatricians. In this systematic review, we examine recruitment and retention efforts targeting students of color, and curricula of geriatric medical programs in the U.S. We offer recommendations toward incentivizing physicians of color to enter geriatrics, strategies to support decolonization of geriatric medical curricula in undergraduate medical education programs, and the development of mentorship and pipeline programs to increase diversity in the geriatric physician workforce.

TRAINING CLINIC PROVIDERS ON ADVANCE CARE PLANNING IMPROVES PROVIDER SELF-EFFICACY

Jeffrey Graupner,¹ Sandy Tun,² Carolyn Read,³ Amena Qureshi,³ Cassie Lee,⁴ and Katherine Thompson,¹ 1. *University of Chicago, Chicago, Illinois, United States*, 2. *University of Chicago Medicine, Chicago, Illinois, United States*, 3. *Oak Street Health, Oak Street Health, Illinois, United States*, 4. *Oak Street Health, Chicago, Illinois, United States*

Advance care planning (ACP) is a vital step to ensure patients receive and prioritize the care that best aligns with

their end-of-life wishes, including discussion and documentation of an advance directive. Significant gaps in ACP among underserved populations have been well documented. Research suggests a successful strategy for increasing the communication between provider and patient about ACP is to educate clinicians on this important issue. Three, 2.5 hour training sessions were provided to healthcare staff of a large chain of older adult primary care clinics across three states. Lecture materials were created and presented by a palliative care (PC) physician and PC nurse practitioner. Presentations were held both in person and virtually. Participants were asked to complete a pre/post-training survey online which included a validated 17-item ACP Self-Efficacy Scale (Baughman, 2017), perceived barriers checklist, and additional quality improvement measures. A total of 131 providers attended one of three training sessions. 76 providers (58.0%) and 47 providers (35.9%) completed pre- and post-training surveys respectively. Scores on a 17-item validated ACP Self-Efficacy Scale were significantly higher after training (Wilcoxon signed rank test, $Z = 4.42$, $p < .001$). Participants ranked "lack of time" as the number one barrier to having ACP conversations both before and after the training, whereas "lack of training" ranked 2nd and fell to 7th after the training. These initial results suggest ACP self-efficacy among providers can be increased through a one-time training session. Previous literature has highlighted the importance of provider self-efficacy as factor in increasing ACP conversations with patients.

Session 9225 (Poster)

Education on Aging and Older Adults

A RETROSPECTIVE STUDY OF RETIRED ACADEMICS: LONG-TERM CAREER BENEFITS OF PAST MENTORING BEHAVIORS

Giovanna Garrido Blanco,¹ Jordan Boeder,² Veronica Fruht,³ Kevin Erikson,² Sarah Hwang,² and Thomas Chan,² 1. *California State University Northridge, Chanhassen, Minnesota, United States*, 2. *California State University Northridge, Northridge, California, United States*, 3. *Dominican University of California, Dominican University of California, California, United States*

While there is extensive literature on the benefits of mentoring for mentees, less is known about the impact of those relationships on mentors, particularly, after mentors complete their careers (i.e., retirement). For academics, the time and energy spent mentoring students can either be beneficial or costly to productivity. This study explores the associations between past mentoring and present evaluations of retired academics' careers, seeking to investigate the long-term career benefits of mentoring. Understanding the evaluation of older adults' careers at retirement in relation to their prior engagement in mentoring is critical, as mentoring is an integral component of careers in academia. Survey data were collected from a national sample of 277 retired academics averaging 73.6 (SD=6.2) years old and 7.7 (SD=5.8) years post-retirement. Results from structural equation models demonstrated that retired academics who reported having more proteges ($\beta = .19$, $p = .024$) and engaged in more

mentoring behaviors ($\beta = .18$, $p = .027$) exhibited increased objective career benefits. Providing more mentoring functions was also associated with higher subjective career achievement ($\beta = .33$, $p < .001$). Interestingly, the number of mentees and mentoring behaviors were not correlated to career satisfaction. Findings from the current study demonstrate the association between past mentoring experiences with career success. Examining the link between mentoring behaviors and overall assessments of career in retirement offers important insight into the long-term benefits of mentoring in higher education training prompting further research into the realization of these benefits in later life.

APPLYING THE NEW WORLD KIRKPATRICK MODEL TO EVALUATE AN ONLINE TRAINING COURSE INTRODUCING A MULTI-SENSORY DEVICE

Jennifer Perion,¹ Victoria Steiner,² Jennifer Kinney,³ Kimberly McBride,² and Barbara Saltzman,⁴ 1. *University of Toledo, Temperance, Michigan, United States*, 2. *University of Toledo, Toledo, Ohio, United States*, 3. *Miami University, Oxford, Ohio, United States*, 4. *University of Toledo, University of Toledo, Ohio, United States*

Online education offers care providers flexibility and convenience. Applying the New World Kirkpatrick Model of training evaluation, this descriptive study evaluated the design and content of a 30-40 minute online training course that introduces direct-care workers to a multi-sensory device to help manage dementia symptoms in older adults. Following course completion, an online survey obtained ratings of engagement (i.e., aesthetics, ease of use, novelty, and involvement), relevance, and knowledge/skills gained from the training using a 5-point Likert scale. A convenience sample of 72 undergraduate students enrolled in health science and human service programs at a Midwestern university participated. The majority were white (83.3%), non-Hispanic (81.9%) females (88.9%). Most participants agreed or strongly agreed (median=4) with positive statements related to engagement with the course. Statements about relevance to their intended career were rated even higher (median=5). Wilcoxon signed-rank tests for matched pairs revealed statistically significant improvements on self-reported pre-post knowledge/skills scores ($p < .005$). The results indicated that participants found the training aesthetically pleasing, easy to use, novel, and that it encouraged user involvement. Participants thought the topics covered were relevant to the professional career they are pursuing, and they learned new knowledge/skills. Responses to open-ended questions suggested improvements to the design (e.g., color choice) and content (e.g., expanded topics and resources). Future research will evaluate a revised course with direct-care workers who will use the multi-sensory device in long term care facilities. Subsequently, an intervention study will determine the effectiveness of the device in increasing the well-being of people with dementia.

EFFECT OF EXCHANGE THROUGH KENDO ON THE IMAGE OF THE ELDERLY OF JUNIOR HIGH SCHOOL KENDO CLUB MEMBERS

Daisuke Matsumoto, and Hayato Uchida, *University of Hyogo, Himeji-city, Hyogo, Japan*

This study targeted junior high school kendo club members who have practice experience with elderly kendo

practitioners and examined the image of the elderly and the related factors that intergenerational exchange through kendo brings to the junior high school members. Kendo is one of the traditional Japanese martial arts. The subjects in this research were 193 players who practiced with the elderly kendo practitioners in Osaka prefecture. As a result of factor analysis to clarify the structure of the image, the "evaluation" factor and the "activity / competence" factor were extracted as in the previous research, and it was suggested that the junior high school players generally had positive image regarding the elderly practitioners. As a result of logistic regression analysis to clarify the factors related to the high/ low scores in the image of elderly kendo practitioners, "evaluation" factor showed a significant relationship between "intimacy with elderly practitioners" and "empathic interest", and "activity / competence" factor indicated a significant relationship between "gender" and "intimacy with elderly kendo practitioners." Although it is pointed out that the traditional style of kendo and the image of elderly kendo practitioners have a negative impact on children, it may be possible to control these factors through an appropriate guidance and approach depending on the children's stage of growth .

EXAMINING THE EXPERIENCES OF ADULT LEARNERS IN HIGHER EDUCATION

Jyotsna Kalavar,¹ Kirsten Magda,² and Raquel Ariyo,² 1. Georgia Gwinnett College, Lawrenceville, Georgia, United States, 2. Georgia Gwinnett College, Georgia Gwinnett College, Georgia, United States

In the last decade, there has been a shift of more non-traditional adult learners returning to pursue undergraduate education. Though traditional age students are in the majority, a rising population of adult learners has been steadily increasing. They are typically students who are 25 years and older, attend part-time, work full-time, and tend to juggle family or dependent demands with school-work. Studies show that these adult learners are at high-risk for academic underachievement and dropping out. However, educational institutions still operate with the same traditional learning paradigm that they previously used (without acknowledging the wealth of life experiences that adult learners bring), leading us to the question of how adult learners perceive their academic learning experiences. In this study, 171 adult learners (students aged 25 and older at the time of matriculation) at a regional college in Atlanta, participated in an online survey that examined their academic experiences, specifically meaningfulness of coursework, course delivery approaches, and the advantages as well as disadvantages of being an adult learner. Majority were females (83%), and the ethnic breakdown was as follows: White (41%), African American (26%), Hispanic (12%), and 22% reported other. Results of this study indicate that academic institutions need to pay attention to the learning experiences of this burgeoning student population. Understanding their perspectives on their academic experiences hold major implications for long-term meaningful change in academia.

GRANDPARENTS AND PARENTS: AN ESSENTIAL PARTNERSHIP FOR LONGEVITY SOCIETIES

Paris Strom, Auburn University, Auburn University/Auburn, Alabama, United States

This presentation hypothesizes that an innovative collaboration by the adult generations will be necessary to enable conditions needed for family success in a longevity society. Unprecedented challenges of parents and grandparents are examined. Reasons why adults have to regard youth as a source of learning about their unique experiences in an age-separated society are explained. International curriculum development studies to support families of children from birth through adolescence are described. A curriculum that provides a common knowledge base about child and adolescent guidance is proposed to harmonize efforts of adults to support younger relatives. Curriculum for retirees should focus on continuing responsibilities other generations expect of them, learning about the lives of younger family members, and gaining awareness of parenting practices to reinforce lessons. Training volunteers in assisted living and long-term care facilities to be indigenous leaders of grandparent classes is discussed as a practical way to offer relevant learning and improve social support. Instruments are examined that assess ethnic relationships between adult generations, adults and adolescents, and track results of education intervention.

THE FUTURE OF AGING IN A LONGEVITY SOCIETY: A COURSE FOR HIGH SCHOOL AND COLLEGE STUDENTS

Paris Strom, Auburn University, Auburn University/Auburn, Alabama, United States

Americans, on average, can anticipate living 85 years or perhaps 100 if born in this millennium. This extension of the lifespan has introduced a new stage of human development presenting unfamiliar challenges to policy makers, health care providers, employers, religious institutions, families, individuals, and schools. Education about longevity should begin in adolescence (ages 10-20) with the merger of science, experiences of older generations, and imagination of youth. Content of this online course focuses on the years after adolescence: early adulthood, middle age, retirement, and old age. After reading each of the 16 lessons, cooperative learning teams conduct structured interviews with older relatives, friends or neighbors who are further along in life's journey. All the lessons are augmented by 'what do you think?' tasks used to motivate discussions, structure interviews, decide on reasoning and problem-solving scenarios, identify key concepts to apply, group lesson reviews, and self-evaluation for comparison with peers. If society wants to encourage adolescents to appreciate their national and ethnic heritage, benefit from learning how older generations see situations and interpret current events, and acknowledge the common need for maturity and spiritual development, then older people should become resources for education about longevity.

Session 9230 (Poster)

Elder Abuse and Neglect

CHARACTERISTICS OF FINANCIAL EXPLOITATION IN A SAMPLE OF ISRAELI OLDER ADULTS

Gali Weissberger,¹ S. Duke Han,² and Amit Shrira,¹ 1. Bar Ilan University, Ramat Gan, HaMerkaz, Israel, 2. University of Southern California, Los Angeles, California, United States

Financial exploitation (FE) negatively affects wellbeing in older adulthood. However, characteristics of FE and its health correlates remain poorly understood. In this study, 138 Israeli older adults answered questions regarding FE history, and completed physical and mental health questionnaires. Of 138 participants, 23 reported a history of FE. FE participants were older (M birth year = 1950.35; sd = 9.65) than non-FE participants (M birth year = 1953.79; sd = 6.06; $p = 0.028$) and reported lower household income ($p=0.001$). Groups did not differ in education level or sex breakdown. The FE group reported older subjective age ($p = 0.022$), worse subjective cognition ($p = 0.007$), more depressive symptoms ($p=0.002$), and marginally higher anxiety symptoms ($p = 0.099$) than the non-FE group. Groups did not differ in reported levels of social support or number of medical conditions. When covarying for age, differences between groups in subjective cognition and depressive symptoms remained significant ($ps \leq 0.022$), while subjective age differences became marginal ($p = 0.07$). The FE group responded to follow-up questions regarding FE experiences. Reported perpetrators included companies/businesses (most commonly reported, 30%), strangers, friends/neighbors, service providers, and family. Eleven reported losing 100 NIS to 10,000 NIS, and 10 reported losing 10,001 to over 100,000 NIS. Additionally, six FE participants reported that the FE is ongoing, and two reported additional FE experiences. Findings suggest that FE is related to mental and physical health of older adults. Findings also provide preliminary information regarding characteristics of FE in a sample of Israeli older adults.

COGNITIVE OVERLOAD: HOW TO PROTECT OLDER ADULTS FROM DIMINISHED FINANCIAL DECISION-MAKING CAPACITY

Christopher Heye,¹ Elizabeth Loewy,² and Katie Wade,³

1. *Whealthcare Planning, Belmont, Massachusetts, United States*, 2. *EverSafe, New York, New York, United States*,

3. *Whealthcare Planning, Belmont, Connecticut, United States*

The aging population in the US poses a major threat to the financial security of older adults and their families. Millions of older adults will need to successfully navigate a multitude of financial and legal issues if they are to safely manage their assets while they are alive, and then securely transfer trillions of dollars to their heirs in accordance with their wishes. But most older adults are less healthy than their younger counterparts, and 25% or more over 65 are likely to suffer from diminished decision-making capacity. In short, older adults in the US will have to make some of the most important financial decisions of their lives just as their decision-making capacity is in decline. We offer recommendations to make it easier for financial services firms, medical professionals, non-profit organizations, and technology companies to work together to find better solutions for managing the complex issues around diminished decision-making capacity that is only likely to worsen in the years ahead.

ELDER FAMILY FINANCIAL EXPLOITATION: FAMILY RELATIONSHIPS ARE NEVER THE SAME

Athena Chung Yin Chan,¹ and Marlene Stum,² 1. *University of Minnesota -- Twin Cities, St Paul, Minnesota, United States*, 2. *University of Minnesota -- Twin Cities, St. Paul, Minnesota, United States*

Millions of families are affected by elder family financial exploitation (EFFE), but the consequences for lifelong intergenerational family relationships and family functioning remain largely unexamined (i.e., parent/child, siblings). This study examines the consequences of experiencing EFFE on the quality of family relationships from the perspective of non-victim, non-perpetrator concerned family members (CFMs). Data from a larger EFFE mixed-methods study were utilized. A voluntary sample of 28 CFMs who had experienced EFFE participated in semi-structured, in-depth interviews and brief surveys. Analysis included identifying quality of family relationship themes from data related to differences EFFE has made in their family. Participating CFMs were primarily adult children of older victims, and siblings of the primary perpetrators. The findings reflect three patterns of changes in quality of family relationships between the CFMs and other family members, including: (a) Restoring trust and recovery within the family, (b) Alliances and taking sides, and (c) Estrangement and cutoff. While families were never the same after experiencing the exploitation, for some was a healing process to accept the family situation and restore and repair trust. Redefining who would be family moving forward was a focus for some families when perpetrators and CFMs took sides and formed allies with others. In the most dramatic changes, siblings, parents and others became cutoff and isolated from other family members. While a loss of relationship quality was common, strengthening of relationships also occurred. Understanding EFFE from an ecological family systems perspective can help to inform needed EFFE interventions, both processes and outcomes.

EXPLAINING ONLINE FRAUD VICTIMIZATION OF OLDER ADULTS VIA CYBER ROUTINES AND LIFESTYLES

Katalin Parti, *Virginia Tech, Blacksburg, Virginia, United States*

The paper compares victim group characteristics: the differences between individuals under 55 and 55 and older, victimized by online fraud committed by a stranger. We test Cyber-Routine Activities Theory (cyber-RAT; Choi, 2008). In addition to active online lifestyle and computer familiarity, we include in the analysis independent variables such as living arrangements, occupation, and the willingness to report and ask for help. A representative sample of US citizens 18 or older was collected using a Dynata research panel in October 2020. We utilized one-way ANOVA on ranks for testing whether older and younger victims' characteristics can be derived from the same independent variables. We find that older victims differ in characteristics from younger victims. Those who live alone or in a marriage with no children, and retired are significantly less victimized by online fraud than those who live with a partner and children and having full-time jobs. Besides, they are less likely to report their victimization, and their online activities and computer familiarity make them more vulnerable to online fraud than younger adults. Our findings suggest that older victims need prevention and intervention solutions designed especially for them. In an aging society, individuals will be increasingly active online and in the job market. Employers must provide internet security training for employees on manipulative online scams. Crime prevention programs must include

awareness-raising on the role of reporting and how to ask for help. Relatives, friends, and caretakers need to be trained in preventing and early recognizing online fraud impacting older adults.

MULTI-METHOD EXAMINATION OF ELDER MISTREATMENT IN THE AGE OF COVID-19

Sonia Salari,¹ Sharon Talboys,¹ Annie Isabel Fukushima,² Heather Melton,¹ Seage Michelle,¹ and Megan Petersen,¹

1. *University of Utah, Salt Lake City, Utah, United States,*

2. *University of Utah, University of Utah, Utah, United States*

A multi-method study exposed COVID-19 influence on the pre-existing epidemic of elder mistreatment in Utah. We found changes in 1) abuse types, 2) service responses, 3) firearm access and 4) policy implications. Gun sales were tracked by news surveillance and FBI National Instant Criminal Background Check System (NICS) for pre-pandemic (2018/2019) and pandemic years (2020/2021). New requests for permits skyrocketed during the pandemic. The 2021 Utah State Legislature loosened restrictions on concealed permits. Domestic violence (DV) Fatality Tracker Data in pre-covid years were compared to 2020-2021. A figure illustrates the prevalence of DV fatalities, ages of victims by year and methods used. We conducted 15 in-depth interviews of stake holders who serve DV victims (shelters, police, etc.). DV shelters had a relative lack of children during the pandemic, but increased use by older persons 60+. Susceptibility to chronic respiratory distress syndrome, required social distance for older persons. DV shelters obtained CARES Act funds to adapt solutions, like placing victims in hotel rooms. Most victims stayed at home, confined with abuser(s), some without technology, so isolation decreased their safety. Evidence suggests some fatalities among elder adults. A case study during the pandemic described a 73-year-old mother's suspicious bank account activity. Bank employees sent police to her home. She was missing, but her co-resident adult son was in possession of her bank cards. She was later found in a shallow grave. Utah households have increased risks of DV fatalities in the wake of the pandemic and for years to come.

SUSCEPTIBILITY TO COVID-19 SCAMS: DOES AGE MATTER?

Julia Nolte,¹ Yaniv Hanoch,² Stacey Wood,³ and David Hengerer,⁴ 1. *Cornell University, Ithaca, New York, United States,* 2. *University of Southampton, Southampton, England, United Kingdom,* 3. *Scripps College, Claremont, California, United States,* 4. *Claremont Graduate University, Claremont, California, United States*

The COVID-19 pandemic has lead to a worldwide surge in COVID-19 related mass marketing scams. While COVID-19 poses higher health risks for older adults, it is unknown whether older adults are also facing higher financial risks as a result of such scams. Thus, the present study examined age differences in vulnerability to COVID-19 scams and factors that might help explain them. In June 2020, 68 younger (18 – 40 years, M = 25.67, SD = 5.93), 79 middle-aged (41 – 64 years, M = 49.86, SD = 7.20), and 63 older adults (65 – 84 years, M = 69.87, SD = 4.50) were recruited through Prolific. Participants responded to five COVID-19 solicitations, psychological measures, and demographic questions. Across solicitations, older adults perceived COVID-19 solicitations to offer significantly fewer benefits

than both younger and middle-aged adults did. However, age groups neither differed in their perception of the solicitations' risks and genuineness nor in their willingness to act in response to COVID-19 solicitations. Overall, intentions to respond to COVID-19 solicitations were positively predicted by higher levels of educational attainment, a previous history of fraud victimization, and higher levels of positive urgency. As expected, stronger genuineness and benefit perceptions positively predicted action intentions, whereas stronger risk perceptions negatively predicted action intentions. Older adults did not exhibit greater vulnerability to COVID-19 solicitations: If anything, they were more skeptical of the benefits associated with these solicitations. Irrespective of age, risk, benefit, and genuineness perceptions were the key factors associated with intention to respond to solicitations.

THE PSYCHOLOGICAL HEALTH CONSEQUENCES OF ELDER ABUSE AND NEGLECT IN SHELTERED HOMES

Khulood Alraddadi, *King Abdulaziz University, Riyadh, Saudi Arabia*

Background: Psychological health effects of elder abuse and neglect in sheltered homes are unknown. Objectives: The objective of the present study was to determine if several types of elder abuse were related to an increased likelihood of negative psychological health. Methods: Data were derived from the elder mistreatment in sheltered homes project, a cross-sectional study conducted in 2018 that included 446 older adults living in 43 sheltered homes. A face-to-face interview was carried out to complete structured questionnaires for participants to assess the psychological health effects of different subtypes of elder abuse. Results: All subtypes of elder abuse were significantly associated with increased prevalence rates of depressive symptoms and sleep problems. Similarly, all subtypes except physical abuse were associated with higher rates of anxiety symptoms. In multivariate regression analysis, Older adults who reported physical mistreatment were three times more likely to experience suicidal ideation (OR=3.28, 95% CI=1.14 to 9.44), while no other subtypes were significantly associated with suicidal ideation. Older adults who report at least one type of abuse were eight times more likely to have depressive symptoms (OR=7.99, 95% CI=4.43 to 14.41), twice as likely to screen positive for anxiety symptoms (OR=2.05, 95% CI=1.20 to 3.49), three times more likely to have sleep problems (OR=3.20, 95% (CI=1.78 to 5.75). All subtypes of abuse were significantly associated with the presence of depressive symptoms, sleep problems, and anxiety symptoms except physical mistreatment. Conclusion: Abuse is common among older adults living in sheltered homes and is associated with negative impacts on psychological health.

Session 9235 (Poster)

Emotions in Older Populations

AGE DIFFERENCES IN AWE AMONG YOUNG, MIDDLE-AGED, AND OLDER ADULTS: EXTENSIONS OF SOCIOEMOTIONAL SELECTIVITY THEORY
Alexandria Ebert, Julie Hicks Patrick, Maya Huggins, Aradhita Yadava, and Sarah Collett, *West Virginia University, Morgantown, West Virginia, United States*

Increases in motivation for the pursuit of emotionally meaningful goals and activities as people age (socioemotional selectivity theory; SST) necessitates the investigation of means in which these goals and activities can be realized. In the present study adults ($N = 130$) aged 25 to 78 ($M = 53.32$; $SD = 15.181$) watched awe-inducing (view of space) and happiness-inducing (comedian Robin Williams interacting with Koko the “talking gorilla”) videos and then completed measures associated with awe, affect, and well-being (measured via PGC Positive and Negative Affect Scales). Analyses of Variance (ANOVAs) were conducted to examine the effect of age (split by young, middle-aged, and older) on experiences of awe and positive affect in response to watching each video. There was a main effect of age on experiences of awe for both videos ($ps < .05$). Specifically, older adults experienced significantly higher levels of awe than young adults ($p < .05$) in response to video 1. They also experienced significantly higher levels of awe than young adults ($p < .01$) in response to video 2. Bivariate correlations among awe, well-being, and happiness were similar in strength and magnitude in each age group ($ps < .05$). Overall, consistent with Socioemotional Selectivity Theory, our findings suggest that affective reactions of awe and happiness, induced by videos, relate to well-being across age-groups. Future work should test whether the use of these awe-inducing videos can improve well-being.

AGE GROUP DIFFERENCES IN RESPONSE TO REPEATED EXPOSURE TO LABORATORY STRESS TASKS

James Miller, and Gloria Luong, *Colorado State University, Fort Collins, Colorado, United States*

Research examining age differences in affect reactivity (i.e. how much affective experiences change in response to stressors) has produced mixed results, suggesting that there are areas of relative strength and weakness in regulatory processes across age-groups. The present study’s goals were to examine potential age-group differences in affect reactivity and subjective task-appraisals across repeated exposures to a psychosocial laboratory stressor. In the Health and Daily Experiences (HEADE) study, younger (18-35 years old; $n=107$) and older adults (60-90 years old; $n=90$) were exposed to the Trier Social Stress Test on three occasions in a laboratory setting over a five-day period. Current affective experiences and task-appraisals were assessed at each session using validated self-report scales, with current affective experiences measured at baseline and task periods to determine affect reactivity. Repeated measures ANOVA analyses were conducted to examine age-group differences in affect reactivity and task-appraisals across sessions. In support of our hypotheses, younger adults showed greater reductions in their negative affect reactivity over time compared to older adults [$F(2, 390) = 8.18, p < .001$]. Additionally, younger adults’ appraisals of task-difficulty decreased [$F(2, 384) = 14.79, p < .001$] and appraisals of task-performance increased [$F(2, 384) = 13.39, p < .001$] across sessions, while older adults’ task-appraisals remained stable. Age-group differences in negative affect reactivity and task-difficulty appraisals were not evident for the first session and only emerged after repeated exposure to the stressors. These results highlight the importance of identifying age-related vulnerabilities

in adapting to repeated stressors, with implications for designing effective interventions aimed at improving health and well-being for older adults.

IMMORAL INTENTIONS VS. ACCIDENTAL ACTIONS: AGE DIFFERENCES IN ENDORSEMENTS OF ANGER AND DISGUST

Alyssa Minton, Jason Snyder, Nathaniel Young, Verena Graupmann, and Joseph Mikels, *DePaul University, Chicago, Illinois, United States*

Given that older adults value social harmony and selectively avoid negativity (Carstensen & Mikels, 2005), we investigated whether older and younger adults differentially react to scenarios in which someone intends to harm others compared to someone who accidentally harms others. Younger ($n = 112, M = 26.23$) and older ($n = 113, M = 66.42$) adults read 8 scenarios in which a perpetrator intentionally acts to harm someone else but is unsuccessful (Desire condition) or a perpetrator accidentally harms someone else (Consequence condition; Giner-Sorolla & Chapman, 2017). Endorsements of anger and disgust toward the perpetrators were measured on 7-point scales (1 = Not at all, 7 = Extremely). Emotion endorsements were submitted to 2 (age) \times 2 (condition) ANOVAs. Anger ($M = 4.81, SD = 1.58$) and disgust ($M = 4.82, SD = 1.54$) endorsements were higher in the Desire relative to Consequence condition ($M = 2.64, SD = 1.33$; $M = 2.49, SD = 1.29$, respectively), $F(2, 221) = 124.03, p < .001$; $F(2, 221) = 156.31, p < .001$, respectively. Moreover, older ($M = 5.17, SD = 1.61$) relative to younger ($M = 4.45, SD = 1.37$) adults were disproportionately disgusted in the Desire condition, $t(102) = 2.45, p = .016$, but no age differences emerged in the Consequence condition. Results indicate that older (relative to younger) adults are disproportionately disgusted when judging a person who intends to harm others. Older adults may respond more strongly than younger adults to malicious perpetrators, as they intentionally upset social harmony.

INTERPERSONAL INTERACTIONS AND AFFECT IN DAILY LIFE AMONG MIDLIFE AND OLDER ADULTS

Robert Stawski,¹ Dakota Witzel,¹ Madeline Nichols,¹ and Susan Charles,² 1. *Oregon State University, Corvallis, Oregon, United States*, 2. *University of California, Irvine, Irvine, California, United States*

Theories of age and emotional wellbeing posit that older age is associated with better affective well-being through avoidance or minimization of distressing experiences and prioritizing positive experiences and emotions. To test these theories, researchers have examined change in affect (i.e., reactivity) associated with negative interpersonal experiences in daily diary studies, given the compromising effects these interpersonal stressors exert on daily affect. In contrast, age differences in the potential affect-enhancing effects of positive interpersonal experiences have been comparatively neglected. Using the second wave of the National Study of Daily Experiences, we evaluated age differences in the frequency of daily negative and positive interpersonal interactions, as well as the affective responses to these interpersonal interactions. Positive and negative affect, as well as negative and positive interpersonal interactions were assessed on eight consecutive evenings. Analyses included 818 participants ($Age = 53.3$,

SD=11.8, Range=34-83; 60% female) who experienced both negative and positive interpersonal interactions during the 8-day protocol. Preliminary results revealed increased frequency of negative interpersonal interactions and decreased frequency of positive interpersonal interactions with age ($p < .01$). Further, negative interpersonal interactions were associated with increases in negative affect and decreases in positive affect ($p < .01$), while positive interpersonal interactions were associated only with increased positive affect ($p < .01$). Finally, modest evidence of age-related reductions in the affective impact of negative, but not positive, interpersonal interactions emerged ($p = .03$). Discussion will focus on how studies of interpersonal interactions in daily life can inform theories of aging and promote emotional wellbeing throughout adulthood and later life.

MARITAL CONFLICT, ANGER EXPRESSION, AND MARITAL INSTABILITY: ASSOCIATIONS BY AGE AND CULTURE

Dakota Witzel, Madeline Nichols, and Robert Stawski,
Oregon State University, Corvallis, Oregon, United States

Positive social relationships, such as high-quality marriages, are associated with better health, especially among older adults. Moreover, negative components in marriages (i.e., disagreements and associated emotional responses) are linked to negative outcomes such as marital disruption (McGonagle et al., 1993) and divorce (Markman et al., 2010). Factors such as marital conflicts and emotion expression threaten marital stability and health and have been shown to decrease with age and in collectivist cultures (i.e., Japan compared to U.S.; Kitayama et al., 2015; Matsunaga & Imahori, 2009). While anger has featured as a specific emotion associated with compromised health and marital quality (Carrère et al., 2005), less is known about how marital conflict and the expression of anger may contribute to marital instability in later life, or differences in these links across age and culture. Using data from married respondents participating in the second wave of the Midlife in the United States (MIDUS, $n = 750$, $\text{Mage} = 55.18$, $\text{SD} = 11.5$, $\% \text{Female} = 50.13\%$) study or first wave of the Midlife in Japan (MIDJA; $n = 706$, $\text{Mage} = 55.26$, $\text{SD} = 13.68$, $\% \text{Female} = 47.73\%$) studies, we examined associations between disagreements, anger expression, and marital risk. Preliminary analyses revealed that marital disagreements and anger expression were each associated with increased marital instability in both the MIDUS and MIDJA samples ($p < .05$). Additionally, the effects of marital disagreements and anger expression did not differ between the two samples or as a function of age. Discussion will focus on the relevance of expression and regulation of emotions for understanding marital (in)stability in midlife and aging and across cultures.

NOSTALGIA FOR A PURPOSE? A COMPARISON OF THREE THEORETICAL FRAMEWORKS IN A LIFESPAN SAMPLE

Jennifer Turner,¹ Jessica Kerin,² Kenzie Delposen,² and Jennifer Stanley,² 1. *Pennsylvania State University, State College, Pennsylvania, United States*, 2. *University of Akron, Akron, Ohio, United States*

Nostalgia is a common experience for most people, but the functions or motivations for nostalgia are unclear. Several

theoretical arguments for the purpose of nostalgia have been offered: nostalgia may reduce anxiety or fear of mortality (i.e., Terror Management Theory), resolve developmental conflicts (i.e., ego-integrity vs. despair), or provide a touchstone to the past (i.e., self-continuity). The goal of this study was to compare these theoretical frameworks among young (YA), middle-aged (MA), and older adults' (OA) descriptions of nostalgia and explore whether content of nostalgia differs by age. We hypothesized that YA would report greater amounts of nostalgia related to self-continuity, MA would report more integrity-related nostalgia, and OA would report more Terror Management. Nostalgia recordings ($N = 593$) were collected during a two-week daily diary study in 108 participants (ages 18-78 years; 60.2% women). Recordings were transcribed and then coded by two trained coders (Magreement=87.4%; $\kappa = .66$, $p < .001$) using a rubric containing three typologies of nostalgia: Terror Management, Integrity v. Despair, Self-Continuity. Only $n = 255$ transcripts could be coded within these typologies. Supporting our hypotheses, YA reported more self-continuity (51.5%) than Integrity (39.4%) or Terror Management (9.1%), and MA reported more Integrity (42.0%), than self-continuity (39.5%) or Terror Management (18.5%). Our third hypothesis was not supported: OA reported self-continuity most frequently (47.5%), followed by Integrity (31.9%) and Terror Management (20.6%). Nostalgia may provide a vehicle for self-reflection as people compare the past to the present, and future research should examine whether emphasis on different types of nostalgia has implications for psychological outcomes like wellbeing.

RECOGNITION OF AFFECTIVE FACES OF DIFFERENT AGE GROUPS

Kim Jinhwi, Seunghee Park, and Jongwan Kim, *Jeonbuk National University, Jeonju, Cholla-bukto, Republic of Korea*

It has been found that valence and arousal are the core affect dimensions in emotional structure. In this study, we hypothesized that there might be differences between different age groups in emotional structure using six facial expression stimuli (angry, disgusted, fearful, neutral, happy, and sad) of three age groups (young, middle-aged, and old). Unlike previous studies asking participants to rate subjective ratings or similarities between stimuli, participants in this study were required to determine whether stimulus pairs were the same or different emotions and reaction time and accuracy were measured for further analyses. We assumed that it would be harder when the stimulus pair is similar whereas it would be easier when the pair is different. The results showed that for the same emotion pair condition, the sad-sad pair had the lowest accuracy and the longest reaction time, while the happiness-happiness pair had the highest accuracy and the shortest reaction time. For the different emotion pairs, angry-disgusted and disgusted-sad was the lowest accuracy and the longest reaction time. For age of the stimuli effect, responses to the old faces had the lowest accuracy and the longest reaction time. The results suggest that identification of emotional stimuli might be affected by emotion category and age. Further study may need to recruit various age groups, because participants in the current study were mostly young adults.

SOCIOEMOTIONAL GOALS AND DEFINITIONS OF EMOTION TERMS: A QUALITATIVE ANALYSIS ACROSS AGE

Irina Orlovsky,¹ Rebecca Ready,² and Bruna Martins-Klein,² 1. *University of Massachusetts Amherst, Northampton, Massachusetts, United States*, 2. *University of Massachusetts Amherst, Amherst, Massachusetts, United States*

Major theories of adult development posit that knowledge about emotion might evolve across the lifespan. Socioemotional Selectivity Theory (SST) and the Strength and Vulnerability Integration (SAVI) models imply that the manner in which older (OA) and younger adults (YA) conceptualize emotions may differ in valence, arousal, reference to social partners, time perspective, and the self. Quantitative accounts of age differences in conceptualizations of emotion-terms offer mixed support for theoretical expectations, but many predictions have yet to be tested qualitatively. In this study, 90 OA and 210 YA provided narrative descriptions of 11 (5 positive, 6 negative) emotion-terms. Responses were coded on valence, reference to self/others, and arousal. O/YA used similar synonyms to define emotion-terms. As predicted, YA used high arousal language in their definitions of negative (OR = 10.29, $p = 0.018$) and positive terms more than OA (i.e. Happy: OR = 1.27, $p < 0.001$); OA referenced other persons such as family and friends (pos: OR = 0.13, $p < 0.001$; neg: OA = 0.32, $p = 0.002$) more than YA. Contrary to predictions, OA self-referenced more often than YA in positive (OR = 0.12, $p = 0.001$) and negative definitions (OR = 0.11, $p = 0.004$); this may be attributed to OA providing more situational examples in their responses than YA. Somewhat consistent with SAVI and SST, OA may reference high-arousal states less when conceptualizing emotions and associate their definitions more with social partners than YA. Future research should address OA greater use of situational examples when defining emotion terms, motivational factors and emotional impact of these age differences.

THE EFFECT OF EVERYDAY STRESSORS AND THE PERCEIVED STRESS REACTIVITY SCALE ON VARIABILITY IN SYMPATHETIC AROUSAL

MacKenzie Hughes,¹ Christopher Hertzog,¹ Shevaun Neupert,² and Scott Moffat,¹ 1. *Georgia Institute of Technology, Atlanta, Georgia, United States*, 2. *North Carolina State University, Raleigh, North Carolina, United States*

This ecological momentary assessment study examined the effect of naturally occurring stressors and perceived stress reactivity on alpha-amylase, a proxy of sympathetic nervous system arousal. There are age-related changes in physiological systems sensitive to stress, so the sample included 174 adults ages 20-78 ($M = 48.65$, $SD = 19.28$). At the beginning of the study, participants completed the Perceived Stress Reactivity Scale (PSRS; Schulz et al., 2005). For 10 consecutive days, participants were prompted five times per day to report exposure to stressors. During the same 10-day period, participants provided seven saliva samples per day, assayed for alpha-amylase. Multilevel modeling was used to examine daily and momentary associations between stressors, the PSRS, and alpha-amylase activity. On a daily basis, stressors did not predict changes in the diurnal alpha-amylase pattern,

but higher perceived stress reactivity predicted steeper diurnal slopes and lower total daily output. A significant cross-level interaction emerged showing people higher in perceived stress reactivity had steeper awakening responses on days they experienced more stressors than usual. On a momentary basis, alpha-amylase levels were higher on occasions when participants reported stressors. In addition, higher levels of perceived stress reactivity predicted lower overall alpha-amylase levels. Findings suggest that 1) stressors are associated with elevations in momentary but not daily aggregate levels of alpha-amylase, and 2) the PSRS has prospective validity as a predictor of stress-related fluctuations in diurnal alpha-amylase patterns. Age was not a significant moderator of the relationship between stressors and alpha-amylase, potentially suggesting the effect of stressors on alpha-amylase activity is age invariant.

Session 9240 (Poster)

End of Life, Death, and Dying

A CASE STUDY ON ANTICIPATED END-OF-LIFE CAREGIVING AMONG THE MILLENNIAL AMERICAN BORN CHINESE

Tongtong Li,¹ Aileen Zhang,² Ruotong Liu,² and Iris Chi,³ 1. *University of Southern California, California, United States*, 2. *University of Southern California, Los Angeles, California, United States*, 3. *University of Southern California, University of Southern California, California, United States*

Millennial American Born Chinese (ABCs) are in a double jeopardy position with end-of-life (EOL) care for their immigrant parents, because of both cultural and generational clashes. There is no existing empirical study about the millennial ABCs' attitudes or behaviors towards EOL caregiving. Our study is the first one to explore the millennial ABCs' anticipated EOL caregiving behaviors, support and resources needed, attitudes towards terminal illness disclosure and advance care planning (ACP) discussion with their parents, and how acculturation influences. A qualitative in-depth phone interview using a case study approach, with a scenario of caring for parents with Parkinson's disease and stage IV lung cancer, was adopted. Participants were recruited via convenience sampling, and a total of 27 (18 females and 9 males with an average age of 25) passed the screening and completed the interviews. Using the directed content analysis, researchers identified two themes: EOL caregiving and EOL decision making, which included five sub-themes: caregiving behaviors, needed supports and resources, care arrangement decision, terminal illness disclosure, and ACP. Both traditional Chinese culture of familism and filial piety, and western culture of autonomy and patients' rights to know were exhibited in every theme. Most participants did not fully understand ACP concept, but they were willing to initiate ACP conversation after comprehending ACP concept. This study constitutes an essential step towards understanding the millennial ABC EOL caregivers' financial, physical, and emotional needs from family, community and government, better establishing corresponding policies, and promoting public education in ACP to benefit this minority group.

AWARENESS OF HOSPICE CARE AMONG RURAL RESIDENTS: FINDINGS FROM SOCIAL DETERMINANTS OF HEALTH FRAMEWORK

Yan Luo,¹ Hyunjin Noh,² Lewis Lee,³ and Hee Lee,⁴ 1. *The University of Alabama, Tuscaloosa, Alabama, United States*, 2. *University of Alabama, Tuscaloosa, Alabama, United States*, 3. *Univeristy of Alabama, Tuscaloosa, Alabama, United States*, 4. *Univeristy of Alabama, Tuacaloosa, Alabama, United States*

Although the demand for hospice care increases as our society ages, the awareness of hospice care among adults in the southern rural region of the US has not been documented. This study aims to assess the rate of hospice care awareness among rural residents living in the Black Belt Region and examine social determinants of health (SDH) associated with the awareness. A cross-sectional survey was conducted among a convenient sample living in rural Alabama (N=182, age=18-91). Participants' awareness of hospice care, demographic characteristics (i.e., age, gender), and SDH (i.e., financial resources strain, food insecurity, education and health literacy, social isolation, and interpersonal safety) were assessed. Lastly, a binary logistic regression was used to examine the association between SDH and awareness of hospice care among participants while controlling for demographic characteristics. The majority of participants had heard of hospice care (82.4%), and older participants (over 50 years old) were more likely to report having heard of hospice care (OR=7.35, $p<0.05$). Participants reporting worries about stable housing (OR=0.05, $p<0.05$) and higher social isolation were less likely to have heard of hospice care (OR=0.53, $p<0.05$), while participants with higher health literacy had a higher likelihood to have heard of it (OR=2.60, $p<0.01$). Our study is the first study assessing the status of hospice care awareness among residents living in the Black Belt Region. This study highlighted that factors including age and certain SDH (i.e., housing status, health literacy, and social isolation) might be considered in the intervention to improve hospice care awareness.

CAREGIVER TASK DIFFICULTIES AT THE END OF LIFE: A LATENT CLUSTER ANALYSIS

Kristin Litzelman,¹ Irene Kizza,¹ and Ashley Berghoff,² 1. *University of Wisconsin-Madison, Madison, Wisconsin, United States*, 2. *University of Arkansas, Fayetteville, Arkansas, United States*

Caregivers engage in myriad tasks from household help to complex medical care. However, little information is available on how caregivers experience individual tasks – particularly key end-of-life tasks such as managing breathing problems or patients' sadness and anxiety. The purpose of this study was therefore to assess task difficulty. Using data from the National Health and Aging Trends Survey and the National Survey on Caregivers (2015-2017), we assessed eleven caregiving tasks in 241 primary caregivers of care recipients in their last month of life. A latent cluster analysis revealed three key clusters: 1) pervasive difficulties, in which caregivers reported difficulty across most or all of the tasks; 2) minimal difficulties; and 3) emotional management difficulties, in which caregivers reported difficulty with managing sadness and anxiety and lower levels of difficulty on the other tasks. Weighted frequency analyses revealed that caregivers

in the pervasive difficulties cluster were most likely to be filial caregivers (85% versus 63% of the full sample, $p<0.05$) or co-residing with the care recipient (49% versus 37% of the full sample, $p<0.05$). Caregivers identified as having pervasive difficulties were also more likely to report providing intensive care, more than 100 hours per week (54% versus 36% of the full sample, $p<0.05$). Care recipient condition was not associated with cluster membership. The findings highlight the need to consider caregiver coping at the task-level and have implications for understanding unmet needs. Future research will assess predictors of cluster membership and how task difficulties are associated with symptoms and well-being outcomes.

CHANGE IN MEDICAL AND HEALTH CARE DECISION-MAKING PATTERNS AT THE END-OF-LIFE: A COHORT OF THE VERY OLD PEOPLE

Xinran Liu, and Steven Albert, *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

How does medical and healthcare decision-making among the very old people change in their last year before death? We explored patterns of decision-making in the Health ABC cohort study in 2011-14 (years 15-17), which involved 12 waves of quarterly phone interviews. When the participant was unable to do the interview, a proxy completed it instead. We identified a sample of 291 decedents (aged 90.0 ± 2.9 at death, 35.7% Black, 52.6% female) with at least 1-year follow-up before death. Percentages of decedents who have made medical or healthcare decisions in the last four quarters before death were 32.0%, 31.2%, 32.6%, 41.9%, respectively. Decedents made more healthcare decisions in the last quarter before death ($P<0.01$), compared to the baseline. Across all quarters, decision-making is most in need for medications (17.6%), hospital admission (13.2%), and ER/urgent care visit (13.2%). We matched a 1:1 sample of survivors at the time of death by race, sex, and age (within ± 3 years). In random effects models with multiple imputations of missing data, we found that decedents were more likely to make healthcare decisions than survivors across all four quarters before death or censor (Odds ratio=1.99, 95%CI: 1.49-2.65, $P<0.01$). The significance still held after adjusting for age, female, race, education, and interview methods. Overall, compared to matched survivors, the frequency of making medical and healthcare decisions among the very old decedents has already been high in the last year before death. This frequency rose sharply in the last quarter before death.

DEATH AND DYING: BOUNDARIES AND ROLES OF FAMILIES AND HEALTHCARE WORKERS DURING PATIENT END OF LIFE

Amber Thompson, and Rebecca Utz, *University of Utah, Salt Lake City, Utah, United States*

While death and dying often occur within or adjacent to the healthcare setting, grief & support of patients at end-of-life (EOL) remain largely within the realm of the family. Given this division of roles, healthcare workers intentionally set professional boundaries that balance their need to be empathetic and compassionate for patient and their families during EOL, while also maintaining a sense of objectivity and detachment which allows them to cope with patient loss and

manage the competing demands of their workday. Tensions occur when healthcare workers are required to cross boundaries at EOL, either voluntarily or involuntarily. Using unobtrusive digital ethnography of a publicly accessible online forum for healthcare providers, this research investigates the boundaries set by families and healthcare workers at EOL, and how EOL circumstances sometimes require healthcare workers to cross or violate these professional boundaries. We suggest that the needs of the family at EOL (not necessarily the patient) serve as the catalyst for both boundary crossing & boundary violations for healthcare workers. Our data reveal that (1) boundary setting and training ought to address the patient-physician-family relationship (not just patient-physician), since the family members are such an integral part of EOL; (2) these EOL dynamics apply beyond the physician and should include all healthcare workers (nurses, etc.). As a result, patient & family centered care may not be fully achieved at EOL due to the ambiguity in the expected roles played by both families and healthcare workers during patient death and dying.

EMBALMING, VIEWING AND THE SOCIAL CONSTRUCTION OF THE CORPSE: TIME FOR ANOTHER LOOK

Redmond Finney,¹ Lisa Shulman,¹ and Raya Kheirbek,²
 1. *University of Maryland School of Medicine, Baltimore, Maryland, United States*, 2. *University of Maryland School of Medicine, University of Maryland School of Medicine, Maryland, United States*

Embalming of the dead is more common in the United States than anywhere else in the world. Battles far from home during the Civil War with concern for contagion from dead bodies being shipped home, compelled President Lincoln to direct the troops to use embalming to allow the return of the Union dead to their homes. Viewings were common with war heroes and culminated with the viewing of Lincoln himself. In the 20th century embalming became a tradition despite substantial evidence indicating environmental and occupational hazards related to embalming fluids and carbon dioxide generated from manufacturing steel coffins before placing in concrete burial vaults. Embalming is promoted and considered helpful to the grieving process when families are comforted by the appearance of a peaceful death. Embalmers are expected to produce an illusion of rest, an image that in some ways disguises death for the benefit of mourners. The dead are carefully displayed in a condition of liminal repose where the 'true' condition is hidden, and death is removed from the actual event. In this paper we highlight the spiritual and cultural complexities of embalming related- issues. We also provide data on the lack of grieving families' preparedness for the financial burden associated with the death of a loved one and the lack of knowledge of alternative options. We propose an innovative process to empower people facing serious illness, and their families to make shared and informed decisions, especially when death is the expected outcome.

EMOTIONAL INTELLIGENCE SKILLS ENHANCE RESPONSIVE CARE OF HOSPITALIZED OLDER PATIENTS

Eva Kahana, and Polina Ermoshkina, *Case Western Reserve University, Cleveland, Ohio, United States*

Our previous research focused on the value of creative problem-solving in late life (Kahana, Kahana, & Ermoshkina, 2021). This paper considers the role of emotional intelligence in creative problem-solving for improving late-life medical care experiences. Emotional intelligence, which is situated at the intersection between the domains of intelligence and personality, can serve as a useful resource promoting personal and social adaptation to problems of old age. Our paper argues for the usefulness of emotional intelligence as older adults deal with challenges of the health care system. Emotional intelligence is rarely studied in gerontological research. Yet, it is required to overcome lack of attention to the patient experience and to provider-patient communication. Problems in communication with staff and in obtaining responsive care are prevalent for hospitalized older adults due to lack of continuity of care as unfamiliar "hospitalist" physicians typically offer care to frail elders. A key adaptive task of older patients involves securing investment by over-worked health care providers. A friendly and extraverted self-presentation by older patients signals to the health care provider the social worth of the patient. Such demeanor can go a long way toward eliciting interest and caring responses from providers. Our paper offers a taxonomy of patient behaviors that can facilitate patient-centered care. Emotional intelligence shown by older patients reflected in expressions of appreciation for staff is likely to facilitate the interest of medical and nursing staff. Potential interventions to foster emotional intelligence among older patients will also be discussed.

FACILITATORS AND BARRIERS TO ADVANCE CARE PLANNING ENGAGEMENT AMONG CHRONIC KIDNEY PATIENTS IN TAIWAN

YuHsuan (Olivia) Wang,¹ and Susan Enguidanos,² 1. *USC, Los Angeles, California, United States*, 2. *University of Southern California, Los Angeles, California, United States*

End-Stage Renal Disease (ESRD) patients experience high rates of cognitive impairment and lower quality of life at end of life. Having an advance care planning (ACP) conversation is associated with better care at end of life and improved care consistency with patient preferences. Taiwan ranks highest in ESRD and dialysis incidence worldwide, highlighting the importance of ACP among this population. Since 2019, the Patient Autonomy Act entitled Taiwanese to engage in ACP, but strategies to promote its uptake and the role of healthcare providers and caregivers in ACP conversations remains unclear. This study aimed to investigate facilitators and barriers to ACP engagement among Taiwanese with kidney disease and their caregivers. In 2020, we recruited 18 adults with stage 3–5 kidney disease and their caregivers. We conducted semi-structured interviews to elicit knowledges and perspectives on ACP. A grounded theory approach was used to guide the analysis of primary themes. Two researchers independently coded the transcripts and met to reconcile codes. The primary barrier to ACP was the misconception that it equated to funeral arrangements. Themes related to ACP facilitators included: trust in the nephrology care team (especially in case managers); straightforward communication; and in-person consultations. Additionally, transplant patients were more likely to have ACP discussions with their loved ones. While kidney disease patients preferred

straightforward communication, caregivers preferred indirect communications. These findings emphasize the critical role of the nephrological care team members. Improving knowledge of ACP and facilitating communication between caregivers and kidney disease patients in Taiwan is needed.

HOSPICE CARE FOR VETERANS: A COMMUNITY EDUCATION PROGRAM

Denise Kresevic, Barbara Heath, and muralidhar Pallaki, VAMC, Cleveland VAMC, Ohio, United States

The impact of trauma on care at end of life and the social isolation of the COVID-19 pandemic highlighted a critical gap in care of terminally ill veterans. It is estimated that 30% of Vietnam Veterans suffer from PTSD, suicide rates are 49% higher in older veterans than nonveterans, and 41% of veterans surveyed report post traumatic guilt. A survey of non-VA hospice agencies revealed many do not screen for PTSD, but desired training in this area. The VA responded to these challenges implementing an initiative to educate community caregivers on PTSD, suicide, and moral injury with expanded tele mental health services. Several VA sites were supported to participate in training focusing on PTSD, suicide, and moral injury and Telemental health. In Northeast Ohio, from 2019-20, 11 community hospice agencies participated in training, including 283 providers, 120 (42%) nurses, 100 (35%) social workers, 29 (10%) volunteers, and 34 (12%) other. A majority of participants post-training (n=160) (84%-94%) reported enhanced knowledge, skills, or attitudes related to resources, education, and communication. Participants rated changes for assessment skills lowest for moral injury (34%), PTSD (41%), and suicide (56%). An analysis of telemental health visits (N=50) revealed that, 56% addressed spiritual support, (22%) family support, (10%) resources/referrals, and (8%) confusion. The majority of telehealth visits were VA initiated (84%), and 10% were hospice initiated. Continued education regarding PTSD, suicide, and moral injury assessment skills is still needed for hospice care providers of veterans. These findings support the use of telemental health for care and consultation.

INTENTION TO COMMUNICATE END-OF-LIFE WISHES AMONG RURAL AFRICAN AMERICANS: IS AWARENESS OF HOSPICE CARE IMPORTANT?

Yan Luo,¹ Hyunjin Noh,² Lewis Lee,³ and Hee Lee,⁴ 1. *The University of Alabama, Tuscaloosa, Alabama, United States*, 2. *University of Alabama, Tuscaloosa, Alabama, United States*, 3. *University of Alabama, Tuscaloosa, Alabama, United States*, 4. *University of Alabama, Tuscaloosa, Alabama, United States*

The intention to communicate end-of-life wishes and its related factors among adults in the southern rural region of the US has not been studied. This study aims to: (1) assess the intention to communicate end-of-life wishes among rural residents living in the Black Belt Region; (2) controlling for demographics and social determinants of health (SDH), examine the relationship between awareness of hospice care and the intention to communicate end-of-life wishes. A convenient sample living in rural Alabama was collected to complete a cross-sectional survey (N=182, age=18-91). Univariate analyses were conducted to assess participants' intention to communicate end-of-life wishes, demographic characteristics,

and SDH. Binary logistic regressions were used to examine the relationship between awareness of hospice care and the intention to communicate end-of-life wishes while controlling for demographics and SDH. The majority of participants were willing to communicate end-of-life wishes to their family (77.5%) or doctors (72.5%). Participants who were aware of hospice care were more likely to be willing to communicate end-of-life wishes to both their families (OR=10.08, p<0.01) and doctors (OR=7.20, p<0.05). Moreover, participants who were older were less likely to communicate end-of-life wishes to their doctors while participants with higher social isolation scores had lower intention to communicate end-of-life wishes to their families (OR=0.53, p<0.05). This is the first study assessing the intention of communicating end-of-life wishes among residents living in the Black Belt Region. This study demonstrated that awareness of hospice care is positively associated with the intention to communicate end-of-life wishes to both families and doctors.

KNOWLEDGE OF HOSPICE CARE AMONG KOREAN AMERICAN IMMIGRANTS IN DEEP SOUTH

Eunyoung Choi,¹ Hee Lee,² Hyunjin Noh,³ and Lewis Lee,⁴ 1. *University of Southern California, LA, California, United States*, 2. *University of Alabama, Tuscaloosa, Alabama, United States*, 3. *University of Alabama, Tuscaloosa, Alabama, United States*, 4. *University of Alabama, Tuscaloosa, Alabama, United States*

Despite the benefits of hospice care in end-of-life care, there is a dearth of research on the knowledge or perceptions of hospice care, particularly among immigrants. A handful number of existing studies with this population have mainly used qualitative research methods. The purpose of the current study was to investigate the knowledge about hospice care and identify its predictors. We used cross-sectional data from 256 Korean American immigrants living in Alabama (Mean age = 44.78, range 23-70, 50.4% female). The outcome variable was measured by whether the respondents had heard of hospice care. Independent variables included sociodemographic (age, gender, education, and income), health (functional limitation and chronic conditions), health care access (health literacy, health insurance, unmet medical needs due to the cost, and social isolation). Logistic regression analyses were performed. About 78% of the respondents reported that they had heard of hospice care. Older age (OR=1.05, 95% CI=1.01-1.09, p<.05), being female (OR=7.13, 95% CI=3.18-15.98, p<.001), and higher levels of education (OR=1.68, 95% CI=1.15-2.45) were significantly related to increased odds of knowledge about hospice care. There were no significant roles of health and health care access factors. Our findings suggest sociodemographic gradients present in immigrants' knowledge about hospice care, emphasizing the need for a targeted intervention to increase the hospice care knowledge.

LENGTH OF STAY IN HOSPICE CARE ACROSS RACIAL/ETHNIC MINORITIES OVER 65 YEARS OF AGE: A DESCRIPTIVE ANALYSIS

Heshuo Yu,¹ and J. Scott Brown,² 1. *Miami University in Oxford, Oxford, Ohio, United States*, 2. *Miami University, Oxford, Ohio, United States*

Purpose: This study aims to explore the relationship between race/ethnicity and length of stay in hospice care among

adults over 65 years of age in the United States. This topic is understudied within a population-representative sample, particularly among non-White decedents. **Methods:** Secondary analysis of data from the 2007 NHHCS (n=3,918). Race/ethnicity included Hispanics/Latinos, Non-Hispanic Whites, African Americans, and other races. Length of hospice stay was measured by the number of days that patients received hospice care from hospice agencies. **Results:** The study found that African Americans have a longer length of stay in hospice agencies than Whites, even after controlling for all other factors in the model. Female gender, older age, and several diseases are covariates that significantly impact length of hospice stay. **Discussion:** Compared to other races/ethnicities, the long length of stay in hospice among African Americans may negatively impact the quality of end-of-life care and quantity of skilled staff visits. Future research is recommended to further explore potential consequences of longer hospice stays, especially within African American communities. Studies with larger samples of minorities that integrate socioeconomic factors need to be done to better study the relationship between length of hospice stay and race/ethnicity.

OLDER COUPLES' ADVANCE CARE PLANNING ENGAGEMENT PATTERNS AND ASSOCIATIONS WITH INDIVIDUAL AND SPOUSAL FACTORS

Hyo Jung Lee,¹ and Bon Kim,² 1. *Nanyang Technological University, Singapore, Singapore*, 2. *Jeju National University, Jeju-si, Cheju-do, Republic of Korea*

This study examines older couples' dyadic patterns of informal and formal advance care planning (ACP) and determines the associations of these patterns with their own and spousal characteristics. Using data from the 2014 and 2016 Health and Retirement Study, we performed a) latent class analysis to identify distinctive ACP engagement patterns and b) multinomial regression models to describe related characteristics of older couples (N = 1,545 couples). We identified four dyadic patterns of ACP engagement: a) high ACP engaging couple (45%); b) high engaging husband – low engaging wife (13%); c) high engaging wife – low engaging husband (11%); and d) low engaging couple (31%). Engagement in informal and formal ACP was associated with both individual and spousal factors: Older couples with advanced age or higher levels of education and wealth were more likely to engage in both informal and formal ACP, whereas only wife's high level of constrain or husband's greater number of depressive symptoms was associated with discordant ACP engagements. Couple-based approach to promote ACP merits older couples with limited resources or poorer psychological health in both or either spouse.

PALLIATIVE CARE KNOWLEDGE AND PLANNING IN U.S. ADULTS

Amy Albright,¹ and Rebecca Allen,² 1. *VA Maine HCS, Gorham, Maine, United States*, 2. *University of Alabama, Tuscaloosa, Alabama, United States*

Palliative care knowledge and health literacy are frequently underestimated in American adults; for example, as measured by the Newest Vital Sign (Weiss et al., 2005), 79.2% (n = 247) of participants within a Geriatrics Clinic sample displayed "adequate" functional health literacy, while

11.8% (n = 37) scored within the "possibly limited" range, and 9.0% (n = 28) scored within the "highly limited" range. There was additionally a significant association between health literacy and age ($r = .15$, $p < .01$) within this sample. The Palliative Care Knowledge Scale (PaCKS; Kozlov et al., 2018) was administered to participants, and higher scores indicated a greater knowledge of palliative care. This construct is particularly important to measure, as racial/ethnic disparities exist within this domain; for example, African Americans may have lower overall knowledge of palliative care services and advance care planning than non-Hispanic Whites (Noh et al., 2018). In the current study, knowledge of palliative care was measured using the PaCKS (Kozlov et al., 2018), and scores represented the widest possible range of 0 to 13 (M = 7.68, SD = 4.08). There was a significant correlation between age and PaCKS score ($r = .12$, $p < .05$), as palliative care knowledge increased with age. Females scored significantly higher (M = 8.29, SD = 3.91) than males (M = 6.81, SD = 4.18), $t(309) = 3.18$, $p < .001$. There was no main effect of race on palliative care knowledge, and post-hoc analysis using Tukey HSD did not demonstrate significant differences between groups.

PATIENT PORTAL USE NEAR THE END-OF-LIFE

Jennifer Portz,¹ John David Powers,² Megan Baldwin,³ David Bekelman,¹ Alejandra Casillas,⁴ Jean Kutner,¹ and Elizabeth Bayliss,³ 1. *University of Colorado, Aurora, Colorado, United States*, 2. *Kaiser Permanente Colorado, Kaiser Permanente Colorado, Colorado, United States*, 3. *Kaiser Permanente Colorado, Denver, Colorado, United States*, 4. *UCLA David Geffen School of Medicine, Los Angeles, California, United States*

Use of patient portals, personal health information websites linked to electronic health records, in seriously ill populations is unknown, as is use by caregivers. We described portal use patterns among adults with serious illness nearing end-of-life and their caregivers within Kaiser Permanente Colorado. Inclusion criteria were: 1) seriously ill patients (defined by KP's "Care Group"), ≥ 18 years of age, who were registered for the portal, and died between 1/1/2016-6/30/2019; and 2) caregivers of these patients, ≥ 18 years of age, registered for a proxy account. Data included user characteristics and portal use metrics summarized monthly over the 12-month period prior to death. Models included an unadjusted linear trend of the days used by month using a generalized estimating equation Poisson model with a log link and an autoregressive correlation structure of order 1. We identified 6,517 seriously ill patients with portal registrations; 163 of these patients had proxy caregivers. Patient users were 77 years old, mostly frail and White, and caregivers were predominantly female. Average days of use among patients was 42.4 days and < 1 day among their caregivers. Number of days used significantly increased by 0.7% per month from twelve months to one month prior to death (95% CI: 0.4%-1.0%; p -value $< .0001$) and peaked 3 months prior to the patient's death. Average use was high in comparison to previous portal research and suggests that as the patient approaches death portal use increases. Future research should explore how portals may serve as indicators for identifying and addressing end-of-life care needs.

PREDICTORS OF ACP COMPETENCY AMONG CHAPLAINS BY SERVICE LINE

Soyeon Cho,¹ Jung Kwak,² Brian Hughes,³ George Hands,⁴ and Moon Lee,⁵ 1. *City University of New York/CityTech, Brooklyn, New York, United States*, 2. *The University of Texas at Austin, Austin, Texas, United States*, 3. *health Care Chaplaincy Network, health Care Chaplaincy Network, New York, United States*, 4. *HealthCare Chaplaincy Network, New York, New York, United States*, 5. *University of Texas, Austin, Texas, United States*

Healthcare chaplains have key roles in palliative care including facilitating advance care planning (ACP). However, little is known about chaplains' competency in ACP. We conducted an online survey with board-certified healthcare chaplains recruited from three major professional chaplains' organizations. We explored correlates of chaplains' competency in ACP facilitation among two groups of chaplains, general and special care (SC) chaplains (chaplains in oncology, intensive care, or palliative units) because SC chaplains are generally more involved in palliative care. The final sample included 481 chaplains with 89.8% reporting ACP as an important part of their work and 71.3% reporting to help patients complete advance directives. There was no significant difference in ACP competency between general chaplain group (n=240; M=39.61, SD=7.0) and SC chaplain group (n=241; M=40.65, SD=5.87). Hierarchical regression analyses revealed differences between the groups. General chaplains who practiced longer as a chaplain (b=1.02, p<.000), were more engaged in ACP facilitation (b=1.06, p<.05), had more positive attitude toward ACP (b=4.04, p<.000), and reported a higher level of participation in shared decision-making with other team members (b=.75, p<.000) were more competent in ACP facilitation. In the SC chaplain group, higher competency was associated with more positive attitude towards ACP (b=2.58, p <.05), and a higher level of participation in shared decision-making (b=1.05, p <.000). Overall, these findings suggest that healthcare chaplains, both general and special care, are competent and actively involved in ACP facilitation. Further systematic studies are warranted to examine the effects of chaplains facilitating ACP on patient and healthcare system outcomes.

TILL DEATH DO US PART?: EXPLORING THE INFLUENCE OF DECEASED ROMANTIC PARTNERS ON THE LIVES OF OLDER WOMEN

Sara Hackett, *University of South Florida, Wesley Chapel, Florida, United States*

Recent research integrating the hierarchical mapping technique (HMT) and the continuing bonds framework has suggested that deceased individuals may be influential social convoy members. Building off this pilot work, the current qualitative descriptive study focused on how older women viewed the role of a longstanding deceased romantic partner in their current social network. Twenty women (Mean age = 78 years), recruited via social media and snowball sampling, participated in one 90-minute semi-structured interview. Each discussed their bereavement journey and completed a HMT diagram to comment on their social network and the presence or absence of the deceased within it. Nineteen participants described the deceased as being an active member of their convoy. Interestingly, 15 women placed

them within the innermost circle of the diagram, separate from their other network members. Thematic analysis of interview transcripts expanded upon the HMT diagram exercise to reveal five major themes: "We're part of each other," "I think he supports me," "He would want me to be happy," "I just feel so grateful," and "I think about him every day but I don't talk about him every day". Perceptions that deceased romantic partners continue to play a key role in participants' lives offers researchers and practitioners with a unique opportunity to examine how losses are experienced and carried into old age. Further, this study may assist with the development of interventions that help support bereaved individuals, specifically, interventions that focus on destigmatizing continuing bond expressions and provide assistance with communicating memorialization preferences.

Session 9245 (Poster)

Environment and Aging, Housing

AESTHETICS AND ENVIRONMENT: WHAT IS THE ROLE OF BEAUTY IN SUPPORTING AGEING WELL?

Holly Nelson-Becker,¹ and Eleanor van den Heuvel,² 1. *Brunel University London, Uxbridge, England, United Kingdom*, 2. *Brunel University London, Brunel University London, England, United Kingdom*

Access to beauty is intrinsic to psychological, social, and spiritual health. Aesthetic sensibility includes awareness initiated in both mind and emotion accessed through nurturing environments (Caspari, Eriksson, & Naden, 2011). While individual tastes vary and aesthetic preferences are culturally conditioned, an appreciation of natural and constructed beauty is fundamental to human meaning-making, creativity, and innovation (Hillman 1998). Beauty is thus an instrumental tool that may support ageing well. We investigated the question of what aesthetics/beauty meant to older adults in England, how they experienced it, and whether experiencing beauty sustained them. Three focus groups were conducted with community dwelling participants aged between 60 and 93 (median age 75) for a total N of 14. Five themes emerged related to experience: an unexpected recognition; an evolving openness to experience; a universal perception available in micro and macro environments; a force that can alleviate depression; and a relational quality of some interactions. The value of beauty was identified through all groups: participants found it difficult to imagine a world with no beauty in it. They wondered if age made discernment capacity greater. Appreciation of beauty in unexpected places like a cracked pot led participants to identify happiness and wellbeing as outcomes of perception. This study suggests that beauty is essential for wellbeing and human flourishing and can emerge in unlikely ways. Implications are that professionals should assist older people to consider the role of beauty in life and develop interventions to consciously keep beauty awakened in normal and aesthetically-deprived environments.

DECREASING BARRIERS TO CARE: VOICES OF RIDERS, DRIVERS, AND STAFF OF A RURAL TRANSPORTATION PROGRAM

Abby Schwartz,¹ Alice Richman,² Mallary Scott,³ Haiyong Liu,³ Weyling White,⁴ and Caroline Doherty,⁴

1. *East Carolina University, School of Social Work, Greenville, North Carolina, United States*, 2. *East Carolina University, East Carolina University, North Carolina, United States*, 3. *East Carolina University, Greenville, North Carolina, United States*, 4. *Roanoke Chowan Community Health Center, Ahoskie, North Carolina, United States*

Eastern North Carolina (eNC) is a rural, poor, and underserved region of the state with 1 in 5 adults living below the poverty level. Residents experience health disparities driven by limited access to healthcare and inequitable distribution of social determinants of health. Project TRIP (Transporting Residents with Innovative Practices) is a potential solution to barriers in accessing care in eNC. Results presented include the first phase of a multi-phase study evaluating and replicating TRIP's effectiveness. Data from qualitative interviews with TRIP riders, drivers, and staff (e.g., case managers) will be presented (n= 20). As a result of the COVID-19 pandemic, interviews were conducted by telephone with the goal of understanding both strengths and weaknesses of the transportation program from riders, drivers, and staff to gain a holistic understanding of TRIP. Of the riders interviewed, the majority (91%) were age 50 and over and African American. Themes that emerged from the data that highlighted strengths of the program included: improved health outcomes, no wait times for pick up or drop offs, cost free, and accommodating service. Themes related to areas of weaknesses or improvement included: needing more transportation vendors and a dedicated TRIP case manager and scheduling concerns. The presentation will conclude with considerations in translating the findings into a pilot and expansion of TRIP in another eNC county (study phases 2 & 3), and how the data can inform the development of transportation interventions in other states, with the goal of increasing access to healthcare for vulnerable rural populations.

DISASTER PREPAREDNESS AMONG MIDDLE-AGED AND OLDER ADULTS: WHO IS THE LEAST PREPARED?

Caitlin Connelly,¹ Kathrin Boerner,² Natasha Bryant,³ and Robyn Stone,⁴ 1. *University of Massachusetts Boston, Somerville, Massachusetts, United States*, 2. *University of Massachusetts Boston, Boston, Massachusetts, United States*, 3. *LeadingAge LTSS Center @UMass Boston, Washington, District of Columbia, United States*, 4. *LeadingAge, Washington, District of Columbia, United States*

Adverse impacts of natural disasters are viewed as particularly concerning for older adults. Disaster preparedness is an important step towards offsetting potential harm. Research comparing different age groups with respect to their disaster preparedness has produced inconclusive evidence. Some studies found older adults more prepared than younger age groups, whereas others found them to be equally or less prepared. To shed light on this issue, we examined disaster preparedness among N = 16,409 adults age 40 and older from the American Housing Survey. Using logistic regression analyses, we compared preparedness levels of four groups – households of middle-aged adults (age 40-64), older adults (age 65-84), oldest old adults (age 85+), and mixed households comprised of both middle-aged and older adults. Findings showed that households of older

adults and the oldest old had significantly higher preparedness levels compared to middle-aged and mixed households, accounting for demographics, living alone, and disability. However, the oldest old group appeared less prepared compared to the older adult group. Thus, while our findings suggest that older adults aged 65-84 may be better prepared for disasters than middle-aged adults, the oldest old group, who are likely at a higher risk of adverse impacts from natural disasters, may be less prepared than their relatively younger counterparts. Therefore, older adults should not be treated as a homogenous group when considering disaster preparedness. Rather, policies and interventions to improve disaster preparedness may benefit from focusing on specific high vulnerability groups.

HIGHER CHILDHOOD ADVERSITY REDUCES ENVIRONMENTAL SATISFACTION AMONG OLDER ADULTS

Ramona Danielson, and Susan Ray-Degges, *North Dakota State University, Fargo, North Dakota, United States*

Background: Childhood adversity (CA) is associated with increased physiological and psychological challenges in adulthood. Normal aging comes with changes that may put adults with a history of CA at increased risk of a poor quality aging experience. Because suitable person-environment fit is an important component of well-being, the present study explored two hypotheses: 1) Higher CA is associated with lower perceived neighborhood quality, and 2) Higher CA is associated with higher perceived inequality in home. Methods: Using MIDUS 2011-2014 Refresher Survey (for this study, N=1,017 adults ages 55-76), Spearman's rho correlation coefficients were run to explore the associations between a previously validated CA score and two environmental satisfaction indices. Perceived inequality in home comprised ratings on six items and perceived neighborhood quality comprised ratings on four items. Results: Hypothesis 1: There was a significant positive association between the perceived inequality in home and cumulative CA, $rs(998) = .200, p < .001$. Hypothesis 2: There was a significant negative association between the perceived quality of neighborhood index and cumulative CA, $rs(998) = -.182, p < .001$. The strength of the associations were weak. Conclusions: Higher cumulative experiences of CA were associated with increased feelings of home environment inequality, and decreased feelings of neighborhood quality. Significant differences were evident after decades had elapsed, demonstrating the long-lasting reach of CA. Further research exploring policy and practice approaches to mitigating the effects of CA is needed to allow aging adults to achieve better person-environment fit and equitable access to successful aging.

MULTI-SECTOR COLLABORATION FOR IMPROVING HOME-BASED NUTRITION SUPPORTS: PROCESS FINDINGS FROM A CLINICAL TRIAL

David Wihry,¹ Jennifer Jain,¹ and Jennifer Crittenden,² 1. *University of Maine, Bangor, Maine, United States*, 2. *University of Maine, University of Maine, Maine, United States*

In-home supports and proper nutrition are critical to post-acute recovery and long-term health management for adults 60 and older. At the same time, such supports are often

difficult to deploy in rural settings. To address these challenges, a unique multi-sector consortia was formed between a local Area Agency on Aging, a healthcare system, a health technology company, and a university to conduct a clinical trial of a novel in-home health technology program coupled with customized chronic care nutrition support. Early stage clinical trial development required coordination across health and community-based organizations to develop a pathway for older adults to access the in-home project supports. At the conclusion of the year one, six project partners were interviewed using a semi-structured interview protocol examining the strengths of early project design and challenges inherent in the early phases of a community-based clinical trial. Thematic analysis uncovered six themes instructive in formulating efficacious clinical trial methodologies: 1) Logistical challenges related to the pandemic, including reduced patient numbers and the curtailing of in-hospital recruitment; 2) Partner collaboration as essential to designing preferred project modifications; 3) The challenge of converting project referrals into project enrollees; 4) A new appreciation among community partners regarding institutional review board requirements; 5) Recommendations for addressing emerging staffing challenges; and 6) The overriding importance of engaging older adults in their own care and health promotion post-discharge. Results will inform construction of a replicable model for establishing novel research partnerships that span healthcare, social services, the business sector, and higher education.

NATIONAL ESTIMATES OF CLIMATE-RELATED DISASTERS AMONG OLDER ADULTS WITH DEMENTIA

Katelyn Ferreira,¹ Katherine Ornstein,¹ Sue Anne Bell,² Mohammed Husain,³ Cynthia Yee,³ and Amy Kelley,¹
 1. *Icahn School of Medicine at Mount Sinai, New York, New York, United States*, 2. *University of Michigan, University of Michigan, Michigan, United States*, 3. *Icahn School of Medicine at Mount Sinai, Icahn School of Medicine at Mount Sinai, New York, United States*

Climate-related disasters can have devastating consequences, particularly for the growing population of older adults with dementia. Increasingly, older adults with dementia are aging in place at home, where they often receive assistance for mobility or self-care activities from family and/or paid caregivers. Understanding this population's experience with climate-related disasters is integral to mitigation, preparedness, and emergency response outside of institutional (e.g., nursing home) settings. We aimed to estimate the population of community-dwelling older adults—including those with dementia—who live in counties that experienced climate-related disasters. We used 2000-2016 data from the Health and Retirement Study (HRS), linked 2000-2018 with Federal Emergency Management Agency (FEMA) disaster data. We flagged each occurrence of climate-related disaster (e.g., hurricane, flood) and then identified HRS participants living in counties with a disaster declaration. Using survey weights, we obtained population-level estimates by disaster frequency and sample characteristics. In each two-year HRS period, we found that 14.26-20.50 million community-dwelling adults over age 65 in the contiguous US (32.2%-53.7%) resided in a county with at least one disaster. This includes 0.62 -1.12

million persons with dementia, 67.2%-76.8% of whom are reliant on caregivers. On average (per two-year period), more than one-third (36.3%) of community-dwelling older adults living with dementia lived in a county with a least one disaster. Policy makers and emergency planners should strongly consider the needs of older adults at the intersection of dementia and risk of climate-related disasters, with an eye towards ensuring access to mobility and self-care assistance.

NEW SOLUTIONS FOR "OLD" PROBLEMS: IMPLICATIONS AND OPPORTUNITIES OF INTERGENERATIONAL HOMESHARING

Raza Mirza,¹ Jacalyn Tanner,² James Hull,² Taylor Hocking,² Anna Liu,² Jessica Hsieh,¹ and Christopher Klinger,¹
 1. *University of Toronto, Toronto, Ontario, Canada*, 2. *National Initiative for the Care of the Elderly (NICE), Toronto, Ontario, Canada*

Across North America, many older adults have expressed their preference to live in their own homes and communities for as long as possible — and to 'age in place'. To address challenges faced by older adults living in the community, home-sharing - an exchange-based intergenerational housing approach, has empowered older adults to 'thrive in place' by providing additional income, companionship, and support with household tasks. In 2018, Toronto HomeShare was launched as an intergenerational home-sharing pilot program (n=22), matching older adults (55+) with postsecondary students intending to simultaneously address social isolation and the affordable housing crisis. In 2019, the pilot was adopted as a funded program in the City of Toronto with over 200 participants. Program results highlight unique benefits and challenges for older adults participating in home-sharing: (1) the capacity for intergenerational engagement to fulfill social needs, and (2) the importance of agency facilitation as a determinant of the experience for older adults. Survey findings indicate 88% of participants reported that participation in HomeShare positively impacted their general well-being, 88% reported improved financial security, 94% reported a delay in the need to move out of their community, and 72% felt that participation in HomeShare prevented the need for institutional care. These findings were used to transition Toronto HomeShare into a fully funded program as well as in the development of a national program. Beginning in January 2021 Toronto HomeShare transitioned to Canada HomeShare and will be scaling the program to Vancouver, Winnipeg, Halifax, Calgary, Montreal and other Canadian cities.

OLDER ADULT BEHAVIORAL HEALTH ISSUES IN NEW ENGLAND: FINDINGS FROM THE HEALTHY AGING DATA REPORTS

Taylor Jansen,¹ Chae Man Lee,¹ Shu Xu,² Maki Karakida,¹ Frank Porell,² Nina Silverstein,³ and Beth Dugan,²
 1. *UMass Boston, Boston, Massachusetts, United States*, 2. *University of Massachusetts Boston, University of Massachusetts Boston, Massachusetts, United States*, 3. *University of Massachusetts Boston, Boston, Massachusetts, United States*

Behavioral health issues in older adults are prevalent and have negative consequences on quality of life and overall health, yet are often untreated. The present study compares state and local community rates of behavioral health

indicators of older adults age 60+ in Massachusetts (MA), New Hampshire (NH), Rhode Island (RI), and Connecticut (CT). For this study rates were calculated from the following data sources: Medicare Current Beneficiary Summary File 2014-2018 (2014-2015 MA, NH, and 2016-2017 RI, CT) and the Behavioral Risk Factor Surveillance System (2013-2015 MA, 2014-2016 NH, 2015-2017 RI, CT). Small area estimation techniques were used to calculate age-sex adjusted community rates for more than 170 health indicators (<https://healthyagingdatareports.org/>). This research examines disparities in rates across the 4 states for 4 behavioral health indicators: substance use disorder (SUD), tobacco use disorder (TUD), opioid use disorder (OUD), and excessive drinking. Results varied across states with RI reporting the highest rates of substance (7.0%) and tobacco use (10.8%) disorders, CT had the highest rate of opioid use disorder (2.2%), and MA and RI reporting the highest rates of excessive drinking (9.3%). Overall, MA had the greatest disparities in rates for all indicators (SUD: 6.6% (5.35-15.99%); TUD: 10.2% (2.67-24.20%); excessive drinking: 9.3% (5.63-19.98%)), indicating behavioral health disparities by community are most pronounced in MA. This study found behavioral health issues are prevalent among New England older adults and should no longer be overlooked. Furthermore, visualizing the community rates makes disparities evident and may guide resources and services to areas of highest need.

POST-RECESSION HOUSING INSECURITY AND PHYSICAL AND MENTAL HEALTH OF MIDLIFE AND AGING ADULTS

Aarti Bhat,¹ David Almeida,² and Alexis Santos,² 1.

Pennsylvania State University, State College, Pennsylvania, United States, 2. Pennsylvania State University, University Park, Pennsylvania, United States

Housing insecurity, or limited/unreliable access to quality housing, is a powerful chronic stressor that can negatively affect individual health and well-being. This study extends prior research by examining the effect of multiple forms of housing insecurity on both the mental and physical health of aging adults using the Midlife in the United States study (MIDUS; N = 2532; M age = 63.42; 57% women; 16% black). Participants reported on experiences of anxiety/depression in the past year, number of chronic health conditions experienced in the last year, and experiences of housing insecurity since the 2008 recession (e.g., homelessness, threatened with foreclosure or eviction, missed rent or mortgage payment). 14% of participants reported experiencing one or more housing insecurity events in the aftermath of the recession. Higher levels of housing insecurity were experienced by midlife participants (ages 46-65) and black participants. Regression results showed that, even when controlling for prior health, housing insecurity was significantly associated with higher odds of experiencing anxiety/depression and additional chronic health conditions. These results suggest that housing insecurity experiences are fairly prevalent among midlife and aging adults, and that housing insecurity experiences leave these adults susceptible to compromised mental and physical health. This work has various implications for policy around addressing housing access and affordability issues for aging adults as a public health

concern. Subsequent analyses will examine age, gender, and race/ethnic differences in these associations between housing insecurity and health outcomes.

ROLE OF COMMUNITY CENTERS IN PROMOTING SUSTAINABLE REGIONAL LIFE OF COMMUNITY-DWELLING OLDER ADULTS WITH FRAILTY

Akiko Nishino,¹ Ryogo Ogino,² Takahiro Miura,³ Ken-ichiro YABU,⁴ Kanako TSUTSUMI,⁵ Junichiro OKATA,⁶ Kazuhiko Nishide,⁶ and Tohru IFUKUBE,⁶ 1. *Former The University of Tokyo, bunkyo-ku, Tokyo, Japan, 2. Saga University, Saga, Saga, Japan, 3. National Institute of Advanced Industrial Science and Technology (AIST), Kashiwa, Chiba, Japan, 4. the University of Tokyo, the University of Tokyo, Tokyo, Japan, 5. Former The University of Tokyo, Bunkyo - K u , Tokyo, Japan, 6. The University of Tokyo, bunkyo-ku, Tokyo, Japan*

Japan's long-term care insurance system, which is a formal service, focuses only on older adults requiring care and support. Therefore, to create supportive communities for frail older adults, appropriate measures have been taken to establish community centers within their walking distance. However, the specific functions of these centers largely remain unknown. Accordingly, this study is aimed at clarifying the role of community centers by analyzing their services and management systems. In February 2020, we conducted a questionnaire survey (36% response rate) and four semi-structured interviews in O city, which has 36 community centers (81.45km², 36.4% elderly population). Results from the questionnaires revealed that the most frequent users of the community center were in their 70s (61.5%); such centers tended to provide informal services, such as exercises and cafes. Meanwhile, 57.2% of community centers collaborate with formal service providers. Community centers tend to be operated together with parent facilities, such as hospitals and nursing homes(61.2%). The results of the onsite survey showed that, in three cases, the community centers were situated within 200 meters of the parent facility. The findings show that these community centers facilitated creation of a supportive community that provides informal services to the frail elderly. Furthermore, they are operated in cooperation with formal service providers, hospitals, and nursing care facilities and are located in close proximity to one another. To summarize, the community centers continue to play a role in providing seamless services to the frail elderly even as their physical functions evolve.

ROLE OF HOME-MODIFICATION TRAINING FOR CARE MANAGERS

Akiko Nishino,¹ Yoritaka Harazono,² Moeko Tanaka,² Kazunori Yoshida,² Toko Funaki,² Ryosuke Takada,² Takenori NASU,² and Taketo TOBIMATSU,² 1. *Former The University of Tokyo, bunkyo-ku, Tokyo, Japan, 2. The University of Tokyo, bunkyo-ku, Tokyo, Japan*

With the aging of society, the long-term care insurance system -which includes home modifications to continue living at home- was established in 2000. However, the quality of home modifications has been persistent issue, and effective training is expected to conclusively solve this problem. To this end, the purpose of this study is to clarify the rational for training care managers who plan home modifications.

A survey comprising two sets of questionnaires was conducted; one set encompassed all 62 municipalities in Tokyo, whereas the other involved care manager who participated in training program. The results of the first questionnaire showed that, out of 62 municipalities, 9 (14.5%) provided training on home modification, of which 8 (88.9%) provided training on administrative procedures. In one municipality that provided training on practical aspects of home modification, we provide questionnaires to 59 care managers participating in the training. Lectures on administrative procedures, physical conditions of invalids, and reading drawings were conducted by administrative staff, occupational therapists, and architects, respectively. Afterwards, the participants attended a planning workshop. According to the questionnaire conducted after the workshop, 80.4% of the participants could understand home modifications in the system, 85.5% understood how to modify homes based on the occupants' symptoms and physical conditions, 81.6% could interpret drawings, 90.2% could plan modifications, and 81.6% found the training useful. These findings indicate that the training of care managers has indeed been effective in actual practice. Improving the quality of home modifications through multidisciplinary cooperation is significant in maintaining home life.

WEATHER-RELATED DISASTER IN A DIVERSE COHORT OF AGING ADULTS

Yvonne Michael,¹ Lauren Clay,² Kevin Smiley,³ Rennie Joshi,¹ and Jana Hirsch,⁴ 1. *Drexel University, PHILADELPHIA, Pennsylvania, United States*, 2. *D'Youville College, Buffalo, New York, United States*, 3. *Louisiana State University, Baton Rouge, Louisiana, United States*, 4. *Drexel University, Philadelphia, Pennsylvania, United States*

As climate change contributes to increasing frequency and intensity of weather-related disasters, it is critical to define characteristics that increase risk of poor health outcomes during and after events. Given the aging of the United States (US) population and over-representation of older adults in disaster-prone areas, disaster-related impacts on older adults present a growing public health challenge. We linked data from the REGARDS study, a cohort of 30,107 Black and White adults (mean age 65 years at baseline, 2003-2007), with community data from the National Establishment Time Series database and longitudinal weather-related disaster data from the Spatial Hazard Events and Losses Database for the US. We calculated disaster exposure for each year for the county in which the respondents lived from 2003 – 2015: 84% of county-years showed at least some impacts, including 16% of counties experiencing medium impacts (\$10- \$50 property damage per capita or 2 fatalities) and 12% severe (greater than \$50 per capital or 3 fatalities); this mirrors that of the continental US (77% some impact, 15% medium, 13% severe). REGARDS participants exposed to moderate or severe disasters were more likely to be Black and low socioeconomic status compared to those who were not exposed. For community characteristics, higher disaster exposure was associated with a greater density of resources including ambulatory care, food stores, social services, and destinations for daily living. Our approach showcases how disaster preparedness systems need better data about specific

individual-and community-level factors that increase risk among older adults to better serve communities.

Exercise and Physical Activity

Session 9250 (Poster)

“ALL THEY DO IS WALK”: SUCCESSFUL AGING AND SYMBOLIC BOUNDARIES AMONG A SELF-ORGANIZED MALL WALKERS CLUB

Jason Pagaduan, *University of Toronto, Scarborough, Ontario, Canada*

Objectives: This study examines how successful aging discourse manifests through physical and social participation among members of a self-organized mall walkers club. There is a paucity of research investigating successful aging in situ and theorizing the relationship between successful aging discourse and community participation. I draw on symbolic boundaries—a concept from cultural sociology—as a way to make sense of what mall walkers say and do. **Methods:** I draw on data from 15 months of participant observations and interviews of mall walkers, all of whom are over 65 and predominantly Caribbean-Canadian women **Results:** I identify three common boundaries: personal, interpersonal, and community, that mall walkers draw on to challenge narratives of decline and internalize dimensions of successful aging. **Discussion:** These findings uncover the ways members in a self-organized community reinforce boundaries that highlight how certain dimensions of successful aging as something to be proud of and desirable. This article contributes to research on intersubjective experiences of aging by revealing how successful aging is rooted in community participation, rather than individual achievement.

ACTIGRAPHY-BASED ASSOCIATIONS BETWEEN CHRONOTYPE AND PHYSICAL ACTIVITY IN OLDER ADULTS

Hilary Hicks, Genna Losinski, Alexandra Laffer, and Amber Watts, *University of Kansas, Lawrence, Kansas, United States*

Chronotype is a measure of the time of day people prefer to be most active or to sleep. There is a known relationship between chronotype and engagement in physical activity in young and middle-aged adults, such that individuals with a morning chronotype engage in more physical activity compared to those with an evening chronotype. Our study aimed to replicate this finding in an older adult sample. Actigraphy can be used to measure both physical activity and sleep. Because of its ability to capture information about bedtime and arise time, actigraphy can serve as an objective measurement of chronotype. Participants were 159 older adults (ages 60-89, M = 74.73) who wore an ActiGraph GT9X on their non-dominant wrist for 7 days in a free-living environment. Chronotype was measured continuously using the midpoint of the ActiGraph-calculated sleep interval. We used multiple regression to determine the relationship between physical activity and chronotype adjusting for sex, age, and body mass index. Results suggest that while these variables explain a significant amount of variance in physical activity, $R^2 = 19.0\%$, $F(4, 152) = 8.921$, $p < .001$, there is no

significant relationship between chronotype and total physical activity in our sample, $\beta = -.117$, $p = .114$. These findings are inconsistent with what has been shown in younger samples and suggest that the relationship between chronotype and physical activity may change as one ages. Future research should consider whether particular physical activity intensities (vs. total activity) may have a relationship with chronotype in older adults.

ADAPTING AN EVIDENCE-BASED PHYSICAL ACTIVITY PROGRAM FOR THE REJOIN TRIAL FOR OLDER BREAST CANCER SURVIVORS

Shirley Bluethmann,¹ Eileen Flores,¹ Meghan Grotte,¹ Jared Heitezenrater,² Cristina Truica,³ and Kathryn Schmitz,¹
 1. Penn State College of Medicine, Hershey, Pennsylvania, United States, 2. Penn State College of Medicine, Penn State College of Medicine/ Hershey, Pennsylvania, United States, 3. Penn State College of Medicine, Penn State Cancer Institute, Pennsylvania, United States

Purpose: Physical activity (PA) is a recommended part of breast cancer survivorship. PA promotes survival and mitigates symptoms in older breast cancer survivors (BCS), especially in reducing joint pain associated with adjuvant hormonal treatment. The purpose of this report is to describe adaptations to Fit & Strong!, an evidence-based curriculum, to meet the needs of older BCS. **Methods:** First, we reviewed all educational materials with scientific experts, including specialists in breast and exercise oncology. Next, we conducted semi-structured phone interviews with 3 BCS for an in-depth review of educational materials for the trial. All interviews were recorded and transcribed. Constant comparative analysis was used to identify themes and specify required technical changes. Subsequently, we recruited 3 new BCS to pre-test adapted materials and exercise sessions, complete a follow-up interview to refine our final product and rate acceptability with older BCS. **Results:** Overall, BCS found the materials and experience very acceptable (mean score of 9.5/10). Content changes included simplifying exercise instructions, prioritizing trial-specific content and updating photographs to be more age-appropriate. Due to COVID, the pre-test activity was conducted by Zoom and participants were given additional time and coaching to participate using this technology. BCS said they would prefer to exercise in person but reported the remote experience as very satisfactory. **Conclusion:** Our multi-step adaptation process provided an acceptable intervention to meet the needs of older BCS. Lessons learned will be applied to the forthcoming clinical trial, which will also be conducted remotely to maximize safety and access.

ARE MACHINE LEARNING MODELS USED TO REPRESENT ACCELEROMETRY DATA ROBUST TO AGE DIFFERENCES?

Todd Manini,¹ Chen Bai,¹ Amal Wanigatunga,² Santiago Saldana,³ Ramon Casanova,⁴ and Mamoun Mardini,¹ 1. University of Florida, Gainesville, Florida, United States, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 3. Wake Forest University, Winston-Salem, North Carolina, United States, 4. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States

Regular and sufficient amounts of physical activity (PA) are significant in increasing health benefits and mitigating health risks. Given the growing popularity of wrist-worn devices across all age groups, a rigorous evaluation for recognizing hallmark measures of physical activities and estimating energy expenditure is needed to compare their accuracy across the lifespan. The goal of the study was to build machine learning models to recognizing the hallmark measures of PA and estimating energy expenditure (EE), and to test the hypothesis that model performance varies across age-group: young [20-50 years], middle (50-70 years), and old (70-89 years). Participants ($n = 253$, 62% women, aged 20-89 years old) performed a battery of 33 daily activities in a standardized laboratory setting while wearing a portable metabolic unit to measure EE that was used to gauge metabolic intensity. Participants also wore a Tri-axial accelerometer on the right wrist. Results from random forests algorithm were quite accurate at recognizing PA type; the F1-Score range across age groups was: sedentary [0.955 – 0.973], locomotion [0.942 – 0.964], and lifestyle [0.913 – 0.949]. Recognizing PA intensity resulted in lower performance; the F1-Score range across age groups was: sedentary [0.919 – 0.947], light [0.813 – 0.828], and moderate [0.846–0.875]. The root mean square error range was [0.835–1.009] for the estimation of EE. The F1-Score range for recognizing individual PAs was [0.263–0.784]. In conclusion, machine learning models used to represent accelerometry data are robust to age differences and a generalizable approach might be sufficient to utilize in accelerometer-based wearables.

BARRIERS AND FACILITATORS IMPACTING PHYSICAL ACTIVITY AMONG RURAL AMERICAN INDIAN OLDER ADULTS

Maja Pedersen,¹ Kari Harris,² Jordan Lewis,³ Mattea Grant,² Chelsea Kleinmeyer,⁴ Ashley Glass,⁴ Blakely Brown,² and Diane King,⁵ 1. Stanford University, Stanford, California, United States, 2. University of Montana, Missoula, Montana, United States, 3. Memory Keepers Medical Discovery Team/University of Minnesota Medical School, Duluth campus, Duluth, Minnesota, United States, 4. Confederated Salish and Kootenai Tribal Health Department, St Ignatius, Montana, United States, 5. University of Alaska Anchorage, Anchorage, Alaska, United States

Background. American Indian (AI) older adults experience pronounced health disparities and demonstrate among the lowest levels of physical activity (PA) of racial and ethnic groups. Nearly half of AI older adults live in rural areas, indicating distinct challenges to participation in PA. Research to identify factors influencing PA among this population is missing from the literature, yet is critical to inform culturally relevant PA intervention development and implementation. **Purpose.** To identify barriers and facilitators to PA among rural AI older adults using the ecological model and qualitative methods. **Methods.** A community-based approach was used to conduct semi-structured interviews with rural AI older adults. Interview questions were based on a multi-level ecological model. Content analysis was performed, using an iterative coding process to identify findings. **Results.** Participants' ($n=21$) mean age was 66 years. Barriers and facilitators to PA were

identified across ecological model levels. Barriers included factors such as caregiving and community responsibilities, lack of acceptable areas for walking, and overall lack of community-level support for older adult health. Facilitators included a personal connection to the land and ancestors through PA, multigenerational participation, and supportive tribal policies. Conclusion. This study addressed a critical gap in the literature by identifying barriers and facilitators among rural AI older adults, which can inform PA intervention development. In this way, their voices are uplifted to shape efforts addressing longstanding health disparities through relevant public health interventions.

CARDIO-DANCE EXERCISE TO IMPROVE COGNITION AND MOOD IN OLDER AFRICAN AMERICANS: A PROPENSITY-MATCHED COHORT STUDY

Bernadette Fausto, *Rutgers University-Newark, Newark, New Jersey, United States*

The current study sought to determine the influence of initial sleep quality and body mass index on the cognitive and mood outcomes of a community-based cardio-dance exercise program. Thirty-two older African Americans who participated in a five-month cardio-dance exercise program were propensity-matched to 32 no-contact controls (ages 60 to 88). Participants completed neuropsychological tests of attention, executive function, and memory and a self-reported depression measure at baseline and post-test. Among exercise participants, we observed significant improvements in depression ($\eta^2=.12$, $p=.009$) and attention ($\eta^2=.12$, $p=.009$) relative to controls. Improvements in executive function and attention were most pronounced among exercise participants with poor sleep quality ($\eta^2=.41$, $p=.04$) and with obesity ($\eta^2 = .30$, $p=.001$), respectively. This study provides novel evidence that cardio-dance exercise has the potential to improve depression in older African Americans. For those with poor sleep quality or obesity, exercise can also improve some cognitive outcomes.

COGNITION AND SUBJECTIVE AGE PREDICT PHYSICAL ACTIVITY ENGAGEMENT: A LONGITUDINAL STUDY OF IMPAIRED OLDER ADULTS

Claire Growney,¹ Xianghe Zhu,² and Shevaun Neupert,³
 1. *Washington University in St. Louis, Saint Louis, Missouri, United States*, 2. *North Carolina State University, North Carolina State University, North Carolina, United States*, 3. *North Carolina State University, Raleigh, North Carolina, United States*

Physical activity is an important factor in preventing or slowing cognitive decline. However, the predictors of fluctuations in physical activity in a population that is already experiencing cognitive impairment is not well understood. Subjective age, such as how old one feels, has been tied to many health indicators in cognitively intact populations. Thus, we focused on the within-person associations between subjective age and physical activity as they unfold over time within a sample of cognitively impaired participants. The current study examined 400 reports from measurement burst data consisting of 5 weekly surveys conducted twice

across 6 months from 68 cognitively impaired participants (M age = 70.14 (6.63), range = 60-92). Participants completed a battery of cognitive tests at baseline. At each weekly assessment, participants reported on their physical activity (e.g., exercise, outdoor, flexibility, and strength activities; Yes/No) and subjective age with respect to how old they feel overall and how old they feel mentally. There were longitudinal decreases in physical activity across the bursts, but on occasions when participants felt younger overall or younger mentally there were increases in physical activity. In addition, the effects of mental subjective age depended on cognitive ability, with those scoring lower in cognitive ability appearing to benefit the most from decreases (feeling younger) in mental subjective age. These findings suggest that perceptions of aging, especially within the domain of mental age, are tied to physical activity engagement for older adults with cognitive impairment.

FACTORS ASSOCIATED WITH LATENT CLASSES OF EXERCISE MOTIVATION AMONG PHYSICALLY ACTIVE OLDER ADULTS

Choi Bomi,¹ Susanna Joo,² Changmin Lee,¹ Kwang Joon Kim,³ DaeEun Kim,¹ YoonMyung Kim,¹ and Hey Jung Jun,¹ 1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea*, 3. *Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The objective of this study was to estimate the latent classes of exercise motivation and to find relevant factors in older adults. The sample comprises 179 people who reported practicing physical exercise regularly. We performed Latent Class Analysis (LCA) and multinomial logistic regression. Exercise motivation was observed with six indicators: medical advice, fun, weight loss, leisure, fitness, and socializing. Independent variables of regression analysis included sociodemographic characteristics (age, gender, marital status, education, and household income), health and well-being (subjective health, and life satisfaction), and satisfaction on neighborhood environment (physical, service, and sociocultural aspects respectively). Results of LCA indicated that the three-class model yielded optimal fit indices. Class 1 (7.5%) was labeled as 'mainly for medical advice and socializing'. Class 2 (46.5%) was labeled as 'mainly for fun', while class 3 (46.0%) was labeled as 'only fitness'. Results of multinomial logistic regression showed that males, people with lower education, and higher satisfaction with their sociocultural neighborhood were more likely to be categorized as 'mainly for fun' group compared to the reference group ('only for fitness'). Subjective health was marginally significant ($p<.10$): People with positive subjective health tend to be categorized as 'mainly for fun' than 'only for fitness' group. Satisfaction with their sociocultural neighborhood was marginally significant ($p<.10$) in distinguishing 'only for fitness' and 'mainly for medical advice and socializing' group. The results of this study emphasized the heterogeneity in exercise motivation. Significant factors of exercise motivation in this study implied the importance of individualized interventions to promote exercise participation.

GET MOVING! YOUR BRAIN WILL THANK YOU.

Christina Nunez, Alexandria Nuccio, and Charles Golden, *Nova Southeastern University, Fort Lauderdale, Florida, United States*

Exercise and cardiovascular fitness are important for physical health and well-being. Recent studies show that exercise is associated with cognitive performance across multiple domains including memory, a common complaint for older adults. Data included a ten-word list of delayed recall, a clock drawing activity, and a three-meter walking course derived from the National Health & Aging Trends Study Database (NHATS Round 9). A total of 4977 participants were included in the analysis which was predominantly white (69.7%), non-Hispanic (94.5%), female (59.2%), and between the ages of 70-84 (62.7%). A hierarchical linear regression revealed that performance on the three-meter walking course positively predicted performance on delayed recall, $F(4,3999)=300.257$, $p<.001$, and on the clock drawing activity, which is a common screening task for cognitive decline, $F(4,3978)=156.433$, $p<.001$; accounting for 23.1% and 13.6% of the variability, respectively, over and above known demographic variables. Findings suggest that fitness may be one of many factors that is associated with memory and overall cognitive decline. These findings are timely as many individuals slowed down as a result of the COVID-19 pandemic, resulting in decreases in exercise and physical activity. Not being physically active or exercising may be related to poorer physical and cognitive health, with specific concerns regarding memory. Taking into consideration the fear and anxiety associated with declining memory in late life, it is crucial to explore this area further along with other factors that may contribute to the association and develop new ways for older adults to exercise safely during the COVID-19 pandemic.

GET UP AND GO! AN EVALUATION OF FITNESS AND MEMORY.

Christina Nunez, Alexandria Nuccio, Sophia Perez, and Charles Golden, *Nova Southeastern University, Fort Lauderdale, Florida, United States*

As we age, exercise is increasingly important for physical health and well-being. Recent studies have shown that exercise is associated with cognitive performance across multiple domains, specifically memory, a common complaint for older adults. Data included a ten-word list of delayed recall, a clock drawing activity, and a sit-to-stand task (i.e., a low impact sub-maximal test of functional fitness) derived from the National Health & Aging Trends Study Database (NHATS Round 9). A total of 4977 participants were included in the analysis which was predominantly white (69.7%), non-Hispanic (94.5%), female (59.2%), and between the ages of 70-84 (62.7%). A hierarchical linear regression revealed that performance on the sit-to-stand task positively predicted performance on delayed recall, $F(4,3914)=245.141$, $p<.001$, and on the clock drawing activity, a common screening task for cognitive decline, $F(4,2893)=115.470$, $p<.001$; accounting for 20.1% and 10.6% of the variability, respectively, over and above known demographic variables. These findings indicate that exercise may be one of many factors that is associated with memory and cognitive decline. Given the continuation of quarantine procedures, these findings come at a time of

significant clinical relevance. Research shows that many individuals slowed down because of the COVID-19 pandemic, and current findings suggest that not being physically active may be related to poorer physical and cognitive health, with specific concerns surrounding memory. Future research is essential in this area to tease out of other factor that may be contributing to this relationship and to develop new and innovated modalities for older adults to safely exercise.

IS A LOW INTENSITY WALKING INTERVENTION SUCCESSFUL IN REDUCING DEPRESSION SYMPTOMS IN MIDDLE TO OLDER AGE WOMEN?

Jingchuan Wu, *Pennsylvania State University, State College, Pennsylvania, United States*

Depression is a common syndrome that has a strong negative impact on people's quality of life. Women, especially in middle age, are facing a greater risk for depressive disorders. Increasing one's physical activity level has shown great effects on reducing depression symptoms. The study evaluated the effect of a 12-week goal-directed walking intervention on walking engagement and depression symptoms among middle-aged women. A total of 55 middle to older age female participants (age range: 50-74) were included in the analysis. The 12-week intervention instructed participants to increase 15% of baseline steps every other week. Depression levels were measured pre-and post-intervention by the Center for Epidemiologic Studies Depression Revised Scale (CESD-R). A baseline measure-time structure- was considered as a possible mediator of association between walking and depression. Although no intervention effects were found in steps promotion and depression reduction in this walking program, we found that more depressed or younger participants had lower walking consistency. It suggested that people with higher depression level or younger age require more instruction over time when engaging in physical activity interventions. Additionally, adherence of participants showed a over-time decreasing trend in this self-paced walking program. This inspired us to give timelier adjusts goals and exercise performance feedback to bolster participants' adherence in the future.

PHYSICAL ACTIVITY AND AGING: EXPLORING MOTIVATIONS OF MASTERS SWIMMERS

Susan Brilliant,¹ Maria Claver,² Patti LaPlace,³ and Cynthia Schlesinger,³ 1. *California State University, Long Beach, Redondo Beach, California, United States*, 2. *California State University, Long Beach, Whittier, California, United States*, 3. *California State University, Long Beach, Long Beach, California, United States*

Physical activity has many benefits for the optimal health of older adults (e.g., lowering risk of cardiovascular disease, depression, dementia and falls). However, less than one in four Americans meets guidelines for physical activity and evidence suggests inactivity increases with age. A growing number of unhealthy older adults will strain resources. Masters athletes are one segment of the population that some promote as exemplary because of their remarkable physical functioning. Swimming is a global, fast-growing sport in Masters athletics. This qualitative study explored the motivations and barriers of older adult (60+ years of age) members of a Masters swim club in

Southern California. The researcher used purposive sampling to diversify the sample by selecting male and female participants (N=18) from multiple geographical areas. Guided by a primary research question: Why do Masters swimmers choose swim late in life, when most of their age cohort are becoming less physically active, the researcher conducted semi-structured interviews to delve into the lived experiences of the participants, solicited peer feedback and employed Interpretive Phenomenological Analysis. Four main themes emerged: Masters swimming provided an enjoyable way to slow physical decline; participants felt camaraderie; working out with a group provided challenge and achievement that reinforced their identity as swimmers; and their practice greatly reduced stress. A formidable barrier was revealed when most of the participants expressed longing and regret that they could not swim due to COVID risk and safety guidelines. These findings can be used to design community programs to promote lifelong physical activity participation.

PILOTING THE EFFECTIVENESS OF A TEXT MESSAGING AND FITNESS TRACKING INTERVENTION WITHIN OLDER BLACK WOMEN

Olivio Clay,¹ Veronica Mixon,² William Opoku-Agyeman,³ Meneka Johnson Nicholson,⁴ and Pamela Bowen,⁵
 1. *University of Alabama at Birmingham, Birmingham, Alabama, United States*, 2. *UAB, Birmingham, Alabama, United States*, 3. *Healthcare Management, University of North Carolina at Wilmington, North Carolina, United States*, 4. *Rural Health Medical Program, Inc., Selma, Alabama, United States*, 5. *The University of Alabama at Birmingham, Birmingham, Alabama, United States*

Physical activity (PA) can help lower risk of obesity and type 2 diabetes, reduce anxiety, and reduce risk of Alzheimer's and other related dementias. Despite these benefits, older, obese Black women are not meeting CDC recommended PA guidelines at disproportionate rates. This study aims to identify whether a targeted intervention, Texting Older Sisters to Step (T.O.S.S.), can improve health-related outcomes within older Black women. A sample of 24 Black women (12 per group) age 60 and older who had a BMI > 30 were recruited. The treatment group received text messages previously validated to promote physical activity every day for 12-weeks and were placed in Fitbit communities. The control group received a general health or nutrition-related text message every Sunday. Participants ranged from 60 to 70 years of age with a mean of 64 and 90% had at least some college education. Overall, there was a significant reduction of 1.53 inches in waist circumference, $p < .01$. When the groups were compared, the treatment group showed a 2.16 inch reduction compared to a 0.91 inch reduction in the control group (Cohen's $d=0.54$, a medium effect size). Similarly, the treatment group lost 2.50 pounds on average compared to 1.33 in the control group ($d=0.23$). When the groups were compared on HgA1c, the treatment group was stable with a reduction of 0.01 unit whereas the control group reduction was 0.15 unit ($d=0.23$). Findings provide initial support for the T.O.S.S. intervention and suggest a modification of including nutrition information among the intervention messages.

SILVER SNEAKERS IN CENTRAL PA: ASSESSMENT OF A COMMUNITY BASED EXERCISE PROGRAM IN A MIXED RURAL/URBAN CATCHMENT AREA

Eileen Flores,¹ Sage Nakagawa,² Robinn Moyer,¹ and Shirley Bluethmann,¹
 1. *Penn State College of Medicine, Hershey, Pennsylvania, United States*, 2. *Queen's University, Ontario, Ontario, Canada*

Older cancer survivors present with unique challenges that may impact quality of life and increase physical dysfunction if not properly managed. Regular physical activity (PA) can help mitigate these effects. Silver Sneakers (SS), a free exercise program available to Medicare beneficiaries, has more than 16,000 US locations. To understand capacity of SS to serve older adults in our mixed rural/urban catchment area of Central Pennsylvania, we 1) identified all registered SS program locations in our 28-county catchment area and; 2) conducted phone questionnaires with SS program staff. Approximately 18 gyms closed during the pandemic, leaving a sample of 121 participating gyms. We talked to 80 gyms (66% response rate) to understand member and programming characteristics, training of staff and program marketing. Geographic locations of SS were mixed – 39% in rural and 61% in urban counties; the majority (43%) were located in private gyms or YMCAs. The majority of gyms reported membership was equally mixed by gender and described ages of members as 65-80 years (94%). Program staff said that many members exercised several times per week with friends/family. Program staff also reported that social opportunities (35%) were a primary reason participants remained active in SS. Most (89%) of the facilities were still able to offer SS during the pandemic, with the majority (60%) adapting format to Zoom and other video platforms to conduct classes. Overall, SS programs offer a sustainable option to facilitate access to exercise programs and reduce barriers to PA among older adults in our catchment area.

THE ASSOCIATION BETWEEN LEISURE AND PHYSICAL ACTIVITY LEVEL WITH DEPRESSIVE SYMPTOMS AFTER 5-YEARS OF FOLLOW-UP

Milan Chang,¹ Hrafnhildur Eymundsdottir,² Alfons Ramel,³ Sigurveig Sigurdardottir,³ Vilmundur Gudnasson,³ Lenore Launer,⁴ and Palmi Jonsson,⁵
 1. *The Icelandic Gerontological Research Institute, Reykjavik, Hofuoborgarsvaio, Iceland*, 2. *Landspítali University Hospital, Landspítali University Hospital, Hofuoborgarsvaio, Iceland*, 3. *University of Iceland, Reykjavik, Hofuoborgarsvaio, Iceland*, 4. *National Institute on Aging, Bethesda, Maryland, United States*, 5. *University hospital Landspítali, Reykjavik, Hofuoborgarsvaio, Iceland*

BACKGROUND: Depressive symptoms in older adults are associated with socioeconomic status (SES), medical care, and physical activity. However, there is little evidence on the longitudinal association between level of leisure activity (LA) and physical activity (PA) with depressive symptoms among community-dwelling older adults in Iceland. The study examined an association of LA and PA at baseline with high depressive symptoms (HGDS) assessed after 5 years of follow-up among community-dwelling older adults. **METHODS:** A large community-based population residing in Reykjavik, Iceland participated in a longitudinal study with

5 years of follow-up (n=2957, 58% women, 74.9±4.8 yrs). Those with HGDS or dementia at baseline were excluded from the analysis. The reported activity was categorized into 2 groups as no-activity versus any-activity. Depressive symptoms were assessed by the 15-item Geriatric Depression Scale (GDS) on average 5 years later. RESULTS: After adjusting for demographic and health-related risk factors, those who reported having any LA had significantly fewer HGDS after the follow-up of 5 years (6 or higher GDS scores, Odds Ratio (OR) = 0.46, 95% Confidence Interval (CI): 0.27 ~ 0.76, P = 0.003). However, reporting any PA at baseline was not significantly associated with HGDS (OR = 0.71, 95% CI: 0.51 ~ 1.00, P = 0.053). CONCLUSION: Our study shows that any LA among older adults is associated with having less depressive symptoms 5 years later among community-dwelling older adults while having any PA was not associated with depressive symptoms after 5 years of follow-up.

THE EFFECT OF LOW-INTENSITY DAILY WALKING ACTIVITY ON COGNITIVE AND BRAIN FUNCTION IN OLDER ADULTS

Dana Eldreth,¹ Vijay Varma,² Yi-Fang Chuang,³ and Michelle Carlson,⁴ 1. *Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*, 2. *National Institute on Aging, Baltimore, Maryland, United States*, 3. *National Yang Ming Chiao Tung University, Taipei, Taipei, Taiwan (Republic of China)*, 4. *Johns Hopkins University, Baltimore, Maryland, United States*

Physical activity is an effective intervention to prevent or delay cognitive decline and dementia in older adults; however, many have difficulty achieving recommended moderate- to vigorous-intensity guidelines. This study examined the impact of low-intensity daily walking activity on executive cognitive and brain function in 66 older adults (mean age=67.26 ; SD=6.04). Daily walking activity was measured using a step activity monitor and brain function was assessed using functional magnetic resonance imaging during the Flanker task. Analyses included whole and region of interest (ROI) in the right middle frontal gyrus (RMFG), occipital cortex (OCC) and anterior cingulate (ACC). Partial correlations were performed between step activity, behavioral performance, and ROI activation, adjusting for age and education. Most of the step activity was in the low-intensity range. No associations were observed between step activity and task performance (p>.05). Task-related activation occurred in the RMFG, lateral OCC and paracingulate (p<.01). Increased activation in the RMFG was associated with greater amount $r(62)=.390$, $p=.001$, duration $r(62)=.309$, $p=.013$ and frequency $r(62)=.327$, $p=.007$ of step activity. Stratification by sex revealed a positive association between amount of step activity and RMFG activation in women $r(44)=.360$, $p=.014$, but not men. Whole brain correlation revealed that amount of step activity was positively associated with precuneus activation (p<.01), an area impacted early in Alzheimer's disease. These results support the benefits of low intensity daily walking activity on prefrontal function in older adults and suggest the importance of designing attainable and sustainable physical activity interventions to promote brain health in older adults.

THE EFFECTS OF EXERCISE ON COGNITIVE FUNCTION IN OLDER ADULTS WITH DIFFERENT TYPES OF DEMENTIA: A META-ANALYSIS

Guilherme Balbim,¹ Ryan Falck,¹ Cindy Barha,¹ Jennifer Davis,² Samantha Starkey,¹ Alexis Bullock,³ and Teresa Liu-Ambrose,¹ 1. *University of British Columbia, Vancouver, British Columbia, Canada*, 2. *University of British Columbia-Okanagan, Kelowna, British Columbia, Canada*, 3. *the University of British Columbia, Vancouver, British Columbia, Canada*

Combating dementia is a public health priority, and exercise training is one promising strategy for dementia prevention. However, its efficacy in promoting cognitive outcomes in different types of dementia remains unknown. We conducted a systematic review (N = 27) and meta-analysis (N = 24) of randomized controlled trials with cognitive function as a primary or secondary outcome. We aimed to assess the effect of exercise interventions on the cognitive function of older adults (>60 years) diagnosed with different types of dementia. We synthesized data from 2,441 older adults with dementia. Eleven trials included older adults with multiple types of dementia, eight with Alzheimer's disease, six with unspecified types of dementia, and two with vascular cognitive impairment. We performed random-effects models using robust variance estimation (RVE) and tested potential moderators using the approximate Hotelling-Zhang test (HTZ). Results suggest a small effect of exercise on cognitive function for all-cause dementia (g = 0.18; 95% CI: 0.04, 0.33; p = 0.016); however, the effects did not differ by type of dementia. Moderation analyses showed that trials that did not specify participants' severity of dementia, applied individual-level randomization, and had higher intervention adherence demonstrated larger exercise effects on cognitive function for all-cause dementia. We conclude that exercise promotes small improvements in the cognitive function of older adults with all-cause dementia. More research including different types of dementia is needed if we hope to determine the precise effects of exercise for each type of dementia.

THE INVENTORY OF PHYSICAL ACTIVITY BARRIERS FOR ADULTS 50 YEARS AND OLDER: REFINEMENT AND VALIDATION

Mariana Wingood,¹ Salene Jones,² Nancy Gell,³ Denise Peters,³ and Jennifer Brach,⁴ 1. *University of Vermont, University of Vermont, Vermont, United States*, 2. *Fred Hutchinson Cancer Research Center, Seattle, Washington, United States*, 3. *University of Vermont, Burlington, Vermont, United States*, 4. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Addressing physical activity (PA) barriers is an essential component of increasing PA among the 56-73% of community-dwelling adults 50 years and older who are not performing the recommended 150 minutes of moderate-to-vigorous PA. As there is no feasible, multi-factorial tool to assess PA barriers among this population, we developed and validated a PA barrier assessment tool called the Inventory of Physical Activity Barriers (IPAB). We collected cross-sectional data on 503 adults (mean age 70.1), with 79 participants completing the scale twice for test-retest reliability and 64 completing a cross-over design examining the ability to use two administration formats interchangeably. Our analyses

consisted of exploratory and confirmatory factor analysis, Cronbach alpha, intraclass correlation coefficient, Bland-Altman Plot, and t-tests. Using factor analysis, we identified and confirmed an eight-factor solution consisting of 27 items. The 27-item IPAB is internally consistent ($\alpha = 0.91$), has a high test-retest reliability (intraclass correlation coefficient = 0.99), and can differentiate between individuals who meet the recommended levels of PA and those who do not ($p < 0.001$). The IPAB scores ranged between 1.00-3.11 for the paper format (mean = 1.78) and 1.07-3.48 for the electronic format (mean = 1.78), with no statistical difference between the paper and electronic administration formats ($p = 0.94$), resulting in the conclusion that the two administration formats can be used interchangeably. Participant feedback illustrates that the IPAB is easy to use, has clear instruction, and is an appropriate length. The newly validated IPAB scale can be used to develop individualized PA interventions that address PA barriers among patients 50 years and older.

Session 9255 (Poster)

Falls: Screening, Risks, and Prevalence

CAPTURING CHANGE IN BALANCE CONFIDENCE OVER 30 DAYS: INSIGHTS GAINED FROM A MICRO-LONGITUDINAL STUDY

Tai-Te Su,¹ Aileen Griffin,² Faith-Christina Washington,³ Jacob Sosnoff,⁴ and Shannon Meija,⁵ 1. *University of Illinois at Urbana-Champaign, United States*, 2. *University of Illinois at Urbana-Champaign, Aurora, Illinois, United States*, 3. *University of Illinois at Urbana-Champaign, Champaign, Illinois, United States*, 4. *School of Health Professions, University of Kansas Medical Center, Kansas City, Kansas, United States*, 5. *University of Illinois, Champaign, Illinois, United States*

Balance confidence reflects one's estimate of their ability to maintain balance and avoid falls. Extensive literature has shown the relationships between balance confidence, functional limitations, and falls in later life. However, change in balance confidence, especially within short timescale, remains largely unknown and deserves further research. In this study, we aimed to investigate how older adults' balance confidence would change over 30 days and explore whether baseline characteristics would explain the individual differences in change. We used data from the Daily Balance Project that employed intensive-repeated measurements to examine the dynamics of subjective and objective fall risk across a month. Twenty-one participants (age = 78.6 ± 5.8, 48% female) were enrolled, and individual characteristics were measured upon recruitment. Throughout the study, participants self-reported their daily balance confidence using the Activity-Specific Balance Confidence (ABC) Scale. We performed growth modeling techniques to examine change within a multilevel framework. Our results showed that overall, ABC scores were high (79.9 ± 17.4) at first, but the linear change was non-significant ($b = 0.03$, $SE = 0.21$, $p = .89$) on average. However, we found that balance confidence increased in individuals with higher educational attainment ($b = 0.37$, $SE = 0.13$, $p < .01$) and decreased among those with greater physical fall risk ($b = -0.18$, $SE = 0.07$, $p < .01$) and accurate understanding of fall

risk at baseline ($b = -0.24$, $SE = 0.12$, $p = .04$). Although ABC scores were stable within the period of one month, our study highlights the distinction of individual characteristics in the process of balance confidence appraisal. We suggest that these nuances should be taken into account when developing more fine-grained fall risk assessments and interventions.

COMPARING THE SHORT AND ORIGINAL VERSIONS OF THE ACTIVITIES-SPECIFIC BALANCE CONFIDENCE (ABC) SCALE IN OLDER ADULTS

Chad Tiernan,¹ and Allon Goldberg,² 1. *University of Michigan-Flint, grand blanc, Michigan, United States*, 2. *University of Michigan-Flint, Flint, Michigan, United States*

Balance confidence assessment in older adults has implications for falls and quality of life. It remains unclear whether the original Activities-specific Balance Confidence (ABC-16) scale or the shortened 6-item (ABC-6) scale is recommended. To further inform the decision-making process of balance confidence tool selection, a secondary analysis of an existing dataset consisting of 77 community-dwelling older adults was performed. ABC-16 and ABC-6 association and agreement, internal consistencies, and relationships with self-rated health (SRH) were assessed. Participants were primarily female (80.5%) between the ages of 60 and 87 years. Results indicated a strong association between the scales [$r = .97$, $p < .001$]; $ICC(2,1) = .80$] but limited agreement (95% Limits of Agreement range = 22.1; mean difference of 7.2 points in the direction of the ABC-16). Cronbach's alphas were .95 (ABC-16) and .89 (ABC-6), suggesting high internal consistency for both scales but possible item redundancy with the ABC-16. Regression model 1 (ABC-6 = primary predictor) explained more of the variance ($R^2 = .36$) in SRH compared to model 2 (ABC-16 = primary predictor; $R^2 = .29$). Hotelling's t-test [$t(74) = 2.4$, $p = .008$] indicated that the correlation coefficient (Multiple R) from the ABC-6 model was significantly higher than the correlation coefficient from the ABC-16 model. In conclusion, despite a high correlation, the two scales did not agree strongly and should not be considered interchangeable. Given that the ABC-16 takes longer to administer, does not relate to SRH as strongly, and could have redundant items, the ABC-6 should be considered for balance confidence assessment in older adults.

DESCRIPTIVE EPIDEMIOLOGY OF FALL-RELATED INJURIES AMONG OLDER ADULTS IN ONTARIO, CANADA

Nicolette Lappan,¹ Aleksandra Zecevic,² Yu Ming,¹ Susan Hunter,² and Andrew Johnson,² 1. *University of Western Ontario, University of Western Ontario, Ontario, Canada*, 2. *Western University, London, Ontario, Canada*

The number of older adults is growing rapidly in the province of Ontario meaning there will be more fall-related injuries (FRIs) in coming decades. Falls are the leading cause of injury-related hospitalizations in Canada. The purpose of this study was to describe the prevalence, circumstances, types, and locations of FRIs among older adults in Ontario. Using a population-based retrospective design, we analyzed secondary data from three health administrative databases (NACRS, DAD, RPDB) for 2010-2014. Older adults (≥ 65 years) admitted to an emergency department (ED) with a combined diagnosis of ICD-10-CA

codes for a fall (W00-W19) and injury (S00-S99 or T00-T14) were selected. Descriptive statistics were performed in R and rates were reported per 100,000 population. There were 304,610 FRI ED admissions (3,089/100,000) and 143,210 patients (47.0%) were subsequently hospitalized (1,452/100,000). Females accounted for 63.0% ED and 61.2% hospital admissions. Age-specific rates increased with age at both ED (2,208/100,000 in 65-69 group, 6,552/100,000 in 90+ years old) and hospital (698/100,000 in 65-69 group, 4,364/100,000 in 90+ years old). Females had higher rates of ED (3,503 vs. 2,572/100,000) and hospital (1,598 vs. 1,270/100,000) admissions than males. The most common injury types at the ED were fractures (1,234/100,000), superficial injuries (719/100,000), other or unspecified injuries (572/100,000), open wounds (498/100,000), and sprains, strains, and tears (162/100,000). FRIs are a considerable problem for older adults and better injury prevention strategies are needed for all female age groups, the 90+ year age group of both genders, and fractures.

DEVELOPMENT OF A SCREENING TOOL FOR FEET/FOOTWEAR-RELATED INFLUENCES ON FALL RISK

Mariana Wingood,¹ Jennifer Vincenzo,² Elizabeth Peterson,³ and Christopher Neville,⁴ 1. *University of Vermont, University of Vermont, Vermont, United States*, 2. *University of Arkansas for Medical Science, Fayetteville, Arkansas, United States*, 3. *University of Illinois Chicago, Champaign, Illinois, United States*, 4. *Upstate Medical University, Syracuse, New York, United States*

The effectiveness of multifactorial fall risk assessment and intervention strategies is well documented. Although identifying feet/footwear-related influences on fall risk is a vital fall risk assessment component, few evidence-based resources or screening tools are available. To address this need, we developed the Screening Tool for Feet/Footwear-Related Influences on Fall Risk. Our tool is designed for older adults who are identified as at risk for falling, based on the CDC's Stopping Elderly Accidents, Deaths, and Injuries (STADI) Algorithm for Fall Risk Screening, Assessment, and Intervention. Tool development was informed by results of our systematic review of lower-limb factors associated with balance and falls. Our initial tool was evaluated by an external group of 9 interprofessional content experts. Those experts recommended modification of 8 items and rated the tool's clarity as 81.2/100, appeal as 79.1/100, and clinical feasibility as 76.1/100. After incorporating recommended changes, we completed a modified Delphi study using 8 new interprofessional experts (average years of experience: 19.3). During Phase 1, Delphi participants recommended we combine items with similar treatment recommendations, add a question about orthoses, and increase the specificity of 9 items. This refinement resulted in a 20-item screening tool, which met approval after two rounds of consensus voting. Approval was defined based on the Item Content Validation Index, percentage of agreement > 80% on each item. The high level of agreement illustrates the tool's content validity. Using our tool, an older adult's feet/footwear-related risk factors can be identified and incorporated into an effective multifactorial fall prevention intervention.

FALL-RELATED INJURIES IN OLDER ADULTS AND MEDICATIONS PRESCRIBED WITHIN 30 DAYS PRIOR TO THE INJURY

Yu Ming,¹ Aleksandra Zecevic,² Richard Booth,² Susan Hunter,² Andrew Johnson,² and Rommel Tirona,² 1. *St. Michael's Hospital, London, Ontario, Canada*, 2. *Western University, London, Ontario, Canada*

Fall-related injuries in older adults have serious consequences both for individuals and the public health care system. The purpose of this study was to identify medication classes prescribed within 30 days prior to the injury that were associated with fall-related injuries in older adults. This population-based, case-control study used secondary administrative health care data in Ontario, Canada. The cases were older adults, aged 66 years and older, who visited an emergency department for a fall-related injury. Controls were extracted from the Registered Person Database, and matched by same age, sex and residence area. Medication classes prescribed to both groups were recorded and logistic regression was conducted to examine the association between medications and fall-related injury. The case group included 255,270 older adults who experienced a fall-related injury over the five-year period (2010-2014). After adjustment for sex, age group, residence area, income level and number of medications prescribed, psychotropic medications (i.e., opioids, anti-epileptics, anti-Parkinson's drugs, and antidepressants), drugs for treatment of constipation, infection and benign prostatic hyperplasia, antithrombotic agents, statins and bronchodilators were identified to be related to increased risk of fall-related injuries. In addition to medications already on the list of fall-risk increasing drugs or FRIDs, this study uncovered that drugs for benign prostatic hyperplasia, cephalosporins, biphosphates and bronchodilators increased the risk of fall-related injury in older adults. Well-designed prospective cohort studies considering prescription indication and drug-drug interactions are needed to provide more convincing evidence on medications that may be associated with increased risks of fall-related injury in older adults.

FALL-RELATED INJURY IN OLDER ADULT HOME CARE RECIPIENTS: A DESCRIPTIVE POPULATION STUDY

Danilla Xing,¹ Aleksandra Zecevic,¹ Nicolette Lappan,² and Yu Ming,² 1. *Western University, London, Ontario, Canada*, 2. *University of Western Ontario, University of Western Ontario, Ontario, Canada*

Canada is experiencing a growing aging population leading to an increase in the number of individuals receiving home care. More needs to be known about home care clients who experience fall-related injuries. The purpose of this study was to describe the characteristics of Ontario home care recipients (65 and older) who experienced fall-related injury, and the characteristics of those injuries. We conducted a population-based descriptive study using secondary data from the IC/ES data repository for the period of 2010-2014. Person-level characteristics were extracted from the Resident Assessment Instrument - Home Care and injury characteristics from ICD-10 CA codes for falls (W00-W19) in combination with injuries (S00-S99 or T00-T14), available from the NACRS database. Descriptive statistics and

rates were calculated using R. Results show the population (N= 88,731) was primarily female (67.0%), the largest age group was 85-89 years old (25.5%) and hypertension was the most prevalent (83.0%) chronic condition. Clinical Assessment Protocols (CAPs) indicated need for support in management of IADLs (75.4%), falls (72.3%) and pain (70.3%). Most patients (55.8%) used nine or more medications. In 90 days prior to home care assessment, 39.6% experienced no falls, 32.4% fell once, and 26.1% fell two or more times. Injuries primarily took place within the home (38.2%). Fractures were the predominant injury type (40.8%), followed by superficial injuries (19.7%). These findings create a foundation for fall-related injury prevention in home care and further research on risk identification, the efficacy of CAPs, and home environment adjustments.

SENSORY IMPAIRMENT IS ASSOCIATED WITH RECURRENT FALLS: STUDY OF WOMEN'S HEALTH ACROSS THE NATION

Carrie Karvonen-Gutierrez,¹ Michelle Hood,² Joshua Ehrlich,³ Richard Neitzel,⁴ and Kelly Ylitalo,⁵
 1. *University of Michigan, School of Public Health, Ann Arbor, Michigan, United States*, 2. *University of Michigan, Ann Arbor, Michigan, United States*, 3. *University of Michigan, University of Michigan, Michigan, United States*, 4. *University of Michigan School of Public Health, Ann Arbor, Michigan, United States*, 5. *Baylor University, Waco, Texas, United States*

This study evaluated the relationship between individual and combined sensory impairments (vision, hearing, peripheral nerve (PN)) with recurrent falls in the past year among 1951 women (mean age 65.6 years) from the Study of Women's Health Across the Nation. Sensory impairments were defined as self-reported vision difficulty, hearing loss, or ≥ 4 on the Michigan Neuropathy Screening Instrument. Recurrent falls were defined as ≥ 2 self-reported falls. Hearing was the most commonly reported impairment (39.2%), followed by vision (22.1%) and PN (16.0%). Among those with any impairments, 7.0% of women reported impairments in all domains. Recurrent falls were more common among women with vision (19.4%), hearing (17.3%), or PN impairments (24.7%) as compared to women without sensory impairments (7.0%). The greatest burden of recurrent falls was among women with all three sensory impairments; one-third (34.6%) of women with vision, hearing and PN impairment were recurrent fallers. In an adjusted logistic regression model, vision, hearing, and PN impairments were associated with statistically significantly higher odds of recurrent falls in the past year (odds ratio (OR) = 1.58, 1.76, 2.11, respectively; all $p < 0.01$), after adjustment for age, race/ethnicity, economic strain, and depressive symptoms. The presence of all three sensory impairments was associated with nearly 6-fold increased odds of recurrent falls (OR=5.65, 95% CI 3.25, 9.82) compared to women with no impairments. Sensory impairments often onset during mid-life and early late adulthood. This work demonstrates that these impairments are associated with falls and that women with impairments across multiple sensory domains are at greatest risk.

Family and Intergenerational Relationships

ADULT CHILDREN'S MONITORING, KNOWLEDGE, AND INTERGENERATIONAL AMBIVALENCE

Noriko Toyokawa,¹ Nancy Darling,² and Teru Toyokawa,³
 1. *Southern Oregon University, Ashland, Oregon, United States*, 2. *Oberlin College and Conservatory, Oberlin, Ohio, United States*, 3. *California State University San Marcos, San Marcos, California, United States*

Monitoring aging parents' daily life is an essential task for adult children to ensure their parents' health and safety. The current study examined domains of parents' lives that adult children monitored as caregivers. Based on social domain theory (Smetana, 1999), we hypothesized that adult children would monitor parents' health and safety issues as respecting parents' autonomy in other issues. The study also examined how adult children's belief in need for monitoring and their perception of having actual knowledge of their parents' behaviors and thoughts would relate to the intensity of their intergenerational ambivalence. Adults who had at least one living parent (N=398, Mage=60, SD=7.7, range 45-77) participated in online surveys. Issues of parents' lives that adult children monitored were categorized into four domains by factor analysis: parents' financial safety, health and physical safety, substance use, and plans with other adult children. A series of regression analyses revealed that adult children's sense of need to know about parents' financial safety was associated with lower ambivalence, $B = -.60$, $SE = .18$, $\beta = -.23$, $p = .001$, whereas parents' physical safety was associated with greater ambivalence, $B = .42$, $SE = .19$, $\beta = .17$, $p = .03$. Adult children's perception of their knowledge about parents' financial safety was positively associated with their ambivalence, $B = .58$, $SE = .20$, $\beta = .22$, $p = .004$, whereas adult children's perception of parents' physical safety was negatively associated with their ambivalence, $B = -.42$, $SE = .21$, $\beta = -.14$, $p = .05$. Different meanings of different types of parents' safety issues for adult children as their caregivers and suggestions for future research will be discussed.

AGREE TO DISAGREE: GENERATIONAL DIFFERENCES IN IDEOLOGICAL VALUES AND THE IMPACT ON DEPRESSIVE SYMPTOMS

Rachel Scott,¹ Acacia Lopez,² and Danielle Nadorff,³
 1. *Mississippi State University, Starkville, Mississippi, United States*, 2. *Mississippi State University, Starkville, Mississippi, United States*, 3. *Mississippi State University, Mississippi State, Mississippi, United States*

Family Systems Theory states that values are transmitted between generations within families and, while many of these values are similar between immediate generations, there may be more differentiation in values between generation gaps. Ideological differences between generations may potentially cause subsequent tension and fluctuations in well-being. The current study sought to examine the moderating effect of generation on the relation between ideological values (political and religious) and depressive symptoms. Participants included 419 grandparents (age: $M = 76$, $SD = 5.18$) and

638 adult grandchildren (age: $M = 29$, $SD = 5.57$) from the 8th wave of the Longitudinal Study of Generations (LSOG) data set, collected in 2005. While violations in assumptions for the testing of religious ideology prevented additional analyses with that variable, significant mean differences were found between grandparents and grandchildren in political ideology scores, with grandparents expressing more conservative views. Generation also moderated the relation between political ideation levels and depressive symptoms. These relations trended in opposite directions for each generation (with non-significant conditional effects), such that when grandparents endorsed more conservative values, depressive symptoms decreased. Conversely, when grandchildren endorsed more conservative values, depressive symptoms increased. These findings indicate that while the older generation found a conservative viewpoint to be a protective factor for mental health, this was not true of younger generations, and indicates a need for age-specific cultural factors to be included in clinical intervention plans. Further implications for these findings will be discussed.

AMBIVALENCE AMONG INTERGENERATIONAL RELATIONSHIPS IN OLD AGE

Sofia von Humboldt, Andrea Costa, Sara Silva, and Isabel Leal, *Instituto Superior de Psicologia Aplicada (ISPA), Lisboa, Portugal*

Objective: This study aims to analyze the perspectives of intergenerational relationships between older adults and adult children. For this purpose, a qualitative research was carried out, which analyzes these relations at a cross-national level. **Methods:** Four hundred and twenty four older participants aged 65-97 years, were interviewed. Participants were of three different nationalities and lived in the community. All the interviews went through the process of verbatim transcription and subsequent content analysis. **Results:** Two dimensions of generational ambivalence were revealed from the study; support and the conflict dimensions. Findings of content analysis produced six themes, which represent intergenerational relations between older adults and adult children: older adults-adult children interaction quality; family integration; care and support; definition of limits; distance and alienation; and communication difficulties. **Conclusions:** This study highlighted the diversity of experiences in old age, in relation to intergenerational relationships and underlined the conflicting expectations from older adults in relation to their adult children. **Keywords:** Adult children, ambivalence; conflict; intergenerational relationships; older adults; support.

DEPRESSIVE COGNITIONS IMPACT ON A LATENT GROWTH CURVE MODEL OF DEPRESSIVE SYMPTOMS IN CAREGIVING GRANDMOTHERS

Christopher Burant, Carol Musil, Jaclene Zauszniewski, and Alexandra Jeanblanc, *Case Western Reserve University, Cleveland, Ohio, United States*

Grandmothers caring for grandchildren have elevated levels of depressive symptoms compared to grandmothers who do not provide care. While the CES-D measures the somatic, positive and negative affect, and interpersonal strain symptoms experienced with depression, the Depressive CognitionScale © captures the change in cognitive thinking

that often precedes depression. Depressive symptoms, on the other hand, are state like in nature and describe depressive symptoms that have happened recently. While depressive cognitions, according to Beck's theory of depression, are the first negative thought processes to appear, these typically lead to other, more serious symptoms of depression. Specifically, depressive cognitions reflect negative thinking patterns and not depression. Data were collected on 343 participants in a longitudinal nationwide online research study of caregiving grandmothers. A latent growth curve model was used to track the trajectory of depressive symptoms at four time points (baseline, 2 weeks, 12 weeks, and 24 weeks). As depressive cognitions are the precursor to the development of depressive symptoms, a latent growth curve model was tested to gain an understanding of how depressive cognitions impacts the trajectory of depressive symptoms over time. The model fit the data well ($\chi^2 = 21.025$; $df = 9$; $p = .013$; $TLI = .976$; $CFI = .985$; $RMSEA = .063$). Baseline depressive cognitions had a strong impact on the intercept (Standardized Beta = .76, $p < .001$) and the slope of depressive symptoms (Standardized Beta = -.67, $p < .001$). The continued impact of depressive cognitions over 24 weeks indicates the need for potential interventions to further address depressive cognitions as a way to decrease depressive symptoms in grandmother caregivers.

DEVELOPMENT OF A NEW MEASURE OF INTERGENERATIONAL CONTACT

Karen Hooker,¹ Shelbie Turner,² Shannon Jarrott,³ and John Geldhof,² 1. *Oregon State University, Corvallis, Oregon, United States*, 2. *Oregon State University, Oregon State University, Oregon, United States*, 3. *The Ohio State University, Columbus, Ohio, United States*

Intergenerational relationships are a predictor of greater physical, mental, and emotional well-being; they can reduce ageism and facilitate feelings of purpose and meaning, shown to be important for health and mortality. Surprisingly there are no measures of intergenerational contact (IGC) shown to be reliable and valid across age groups. Therefore, we aimed to develop a psychometrically sound survey measure of IGC. We utilized a three-phase development process, which included a Delphi-style expert panel review of items, focus groups, and validation of the survey via Amazon MTurk. The resulting 18-item survey captures details on and comparisons between both familial and non-familial contact and is appropriate for adults of all ages. We conducted confirmatory factor analyses with the 9-item family and 9-item non-family subscales for 380 young and 256 middle-aged adults reporting on contact with older adults, and 348 older adults reporting on contact with younger adults. The family scale had good model fit across all three groups ($\chi^2(78) = 245.74$, $p < .0001$; $RMSEA = 0.08$, 90% CI = [0.07, 0.10]; $CFI = .94$; $TLI = .92$). After covarying for 2 pairs of items among the middle-age group, the non-family scale had good model fit across all groups ($\chi^2(75) = 217.21$, $p < .0001$; $RMSEA = 0.08$, 90% CI = [0.07, 0.09]; $CFI = .95$; $TLI = .93$), indicating construct equivalence across age groups. The new IGC measure can be used in all adult age groups, making it useful for scientific projects as well as program evaluations. Funded by the RRF Foundation on Aging

INTERGENERATIONAL CONFLICT AMONG ASIAN IMMIGRANT FAMILIES AND PSYCHOLOGICAL WELL-BEING: RESULTS FROM PIETY STUDY

Fatima Abdi,¹ Stephanie Bergren,¹ Lisa Lanza,² and XinQi Dong,² 1. *Rutgers University, New Brunswick, New Jersey, United States*, 2. *Rutgers University, Rutgers Institute for Health, New Jersey, United States*

Research suggests that stress from migration and cultural adjustment may lead to intergenerational conflict (IC) within Asian immigrant families. Current research reports management of IC but fails to acknowledge the consequences it may have on offspring. The PIETY study, a longitudinal study of Chinese adult children (n = 547) in the greater Chicago area, aims to examine the relationship between IC and psychological wellbeing in children of Asian immigrant families. IC is assessed by the sum of items on conflicting opinions with parents based on finances, health, parenting, and lifestyle. Psychological wellbeing was measured by the Perceived Stress Scale with a cutoff value greater than or equal to 14, R-UCLA Loneliness Instrument scored on a binary scale, and Hospital Anxiety and Depression Scale (HADS) Anxiety Subscale with a cutoff value greater than or equal to 8. Logistic regression was conducted and controlled for age, gender, education, income, marital status, and household composition. Every one-point higher conflict with parents was associated with being 2.31 times more likely to experience stress for the adult child (OR: 2.31, 95% CI: 1.49-3.57, p<.001) and being 4.56 times more likely to experience loneliness (OR: 4.56, 95% CI: 2.79-7.43, p<.001). IC, however, had a nonsignificant positive association with anxiety in adult children. The association between IC and psychological wellbeing suggests that conflict is a result of complex factors, for which interventions could be developed to improve psychological wellbeing and resiliency in families who continue to navigate cultural changes in a foreign land.

INTERGENERATIONAL FAMILY LEISURE IN THE COVID-19 PANDEMIC: SOME POTENTIALS, PITFALLS, AND PARADOXES

Tia Rogers-Jarrell,¹ Deanna Vervaecke,² and Brad Meisner,² 1. *York University, Hamilton, Ontario, Canada*, 2. *York University, Toronto, Ontario, Canada*

COVID-19 has significantly changed the way we engage in leisure. The influence of public health measures and messaging on leisure put older and younger people alike at increased risk of stress, anxiety, loneliness, and isolation. Despite these similar experiences, ageism and tensions between generations intensified during the pandemic. Thus, it is imperative to encourage strategies that foster connections and solidarity between generations, such as participating in intergenerational family leisure. Intergenerational family leisure can both attenuate negative outcomes heightened or created by the pandemic (i.e., risk reduction) and increase positive experiences (i.e., wellness promotion). However, it is important to recognize that intergenerational family leisure may not be available, or ideal, for everyone, especially during the pandemic. There are longstanding and pandemic-specific pitfalls to engaging in intergenerational family leisure that need to be considered. Further, the conditions and handling of the COVID-19 pandemic have complicated family leisure in paradoxical ways. Many contradictions emerge as we

navigate social systems and personal experiences when engaging in intergenerational family leisure during the pandemic. This paper critically presents some of the potentials, pitfalls, and paradoxes associated with connecting multiple generations in and through family leisure during the pandemic.

INTERGENERATIONAL STRAIN AND SUBJECTIVE WELL-BEING: THE ROLE OF LEISURE ACTIVITY ENGAGEMENT

Amanda Collins,¹ Jeffrey Stokes,¹ and Elizabeth Dugan,² 1. *University of Massachusetts Boston, Boston, Massachusetts, United States*, 2. *UMass Boston, Boston, Massachusetts, United States*

Family strain is associated with higher numbers of depressive symptoms and lower levels of life satisfaction. Leisure activities are observed to buffer the negative effects of family strain among younger adults, however, this phenomenon is understudied among older adults. This study examines the relationship between intergenerational strain and depressive symptoms and life satisfaction among persons aged 50 and older. The study also examines the moderating effects of gender and leisure activities. The analysis uses the Health and Retirement Study to address these questions. The results suggest that intergenerational strain (p=.000) and being female (p=.000), are associated with more depressive symptoms, while engagement in social leisure activities (p=.04) is associated with fewer. Intergenerational strain (p=.000) and being female (p=.03) are associated with lower levels of life satisfaction, while engagement in solitary (p=.000) and social leisure activities (p=.000) are associated with higher levels. Results from moderation models suggest that as intergenerational strain increases, women have lower life satisfaction and more depressive symptoms as compared to men (p=.000). Also, the association between intergenerational strain and life satisfaction is reduced among respondents who engaged in leisure activities (p=.002-social and p=.000-solitary). Further, the positive relationship between intergenerational strain and depressive symptoms is lower for persons who engage in leisure activities (p=.027-solitary and p=.013-social). Finally, women who engage in social and solitary leisure activities have fewer depressive symptoms than men (p=.037). The study findings imply that the subjective well-being of older persons may be improved in terms of intergenerational strain if they engage in leisure activities.

PROGRAM PRACTICES PREDICT INTERGENERATIONAL INTERACTION AMONG YOUTH AND OLDER ADULTS

Shannon Jarrott,¹ Shelbie Turner,² Jill Juris Naar,³ Rachel Scrivano,¹ and Raven Weaver,⁴ 1. *The Ohio State University, Columbus, Ohio, United States*, 2. *Oregon State University, Oregon State University, Oregon, United States*, 3. *Appalachian State University, Boone, North Carolina, United States*, 4. *Washington State University, Pullman, Washington, United States*

Non-familial intergenerational programs engage younger and older people in shared programming for mutual benefit, frequently involving senior centers or adult day programs and preschools. With growing interest in the potential benefits of intergenerational strategies, it is imperative to know their

effects on participant interaction during intergenerational programming. To address this knowledge gap, activity leaders at five sites serving older adults and/or preschoolers received training to implement 14 evidence-based practices during intergenerational activities involving 109 older adult and 105 preschool participants over four years. We utilized multi-level modeling to test whether variations in implementation of practices were associated with variations in participants' responses to programming on a session-by-session basis. For both preschool and older adult participants, analyses revealed that the implementation of certain practices was associated with significantly more intergenerational interaction. Specifically, when person-centered best practices (e.g., leading activities that are age- and role-appropriate for older adults) were implemented, preschoolers (estimate=5.83, SD=2.11, $p=0.01$) and older adults (estimate=5.11, SD=.10, $p=0.02$) had more intergenerational interaction. Likewise, when environmental-centered best practices were implemented, such as pairing materials between intergenerational partners, preschoolers (estimate=6.05, SD=1.57, $p=0.002$) and older adults (estimate=6.50, SD=1.85, $p=0.001$) had more intergenerational interaction. Our findings reveal session-by-session variation in intergenerational interaction that can be impacted by implementation practices, which highlights the importance of training activity leaders to implement evidence-based practices. Researchers and practitioners should consider how session-by-session variation in program implementation affects participant response.

SUBJECTIVE WELL-BEING, STATUS IDENTITY, AND INTERGENERATIONAL RELATIONS AMONG THE ELDERLY

Jieming Chen, *Texas A&M University - Kingsville, Kingsville, Texas, United States*

This study investigates the influences of intergenerational relations on the subjective wellbeing and status identity of the elderly population in China. The project draws insights from the studies of social mobility and stratification, and that of family relations and old age support. Because of widespread exchange of economic resources across generations and strong sense of connectedness among parent and adult children families that continue to exist in Chinese society today, we hypothesize that older parents' subjective sense of well-being and evaluation of their socioeconomic statuses are positively related with the socioeconomic conditions of their grown children, and the strength of the such relations with them. The study used the data from the 2013 China General Social Survey (CGSS), and the results provide fairly strong support to the hypotheses. The implications of the results on age-based stratification are discussed.

SUPPORT EXCHANGES AMONG VERY OLD PARENTS AND THEIR CHILDREN: FINDINGS FROM THE BOSTON AGING TOGETHER STUDY

Kyungmin Kim,¹ Kathrin Boerner,² Yijung Kim,³ and Daniela Jopp,⁴ 1. *Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *University of Massachusetts Boston, Boston, Massachusetts, United States*, 3. *The University of Texas at Austin, Austin, Texas, United States*, 4. *University of Lausanne, Lausanne, Vaud, Switzerland*

Very old parents and their "old" children are a growing group in industrialized countries worldwide. Care needs of very old parents can be substantial, while children may also face their own age-related issues. However, little is known about support exchanges within very-old parent-child dyads. This study aimed to identify patterns of support exchanges occurring in these dyads, as well as to ascertain individual and relationship factors associated with these patterns. Participants were 114 very old parents (age ≥ 90) and their children (age ≥ 65) from the Boston Aging Together Study. Data were collected using comprehensive, semistructured in-person interviews with both dyad members, including standardized assessments of support exchanges, relationship quality, health, and perceptions of family norms. Actor-Partner Interdependence Models (APIM) were used to predict upward and downward support reported by children and parents. Both dyad members not only reported substantial upward support (given to parents by children) in all domains but also notable amounts of downward support (given to children by parents) in the domains of emotional support, listening, and socializing. Findings showed significant associations of parent functional impairment, parent and child relationship quality, and child perceptions of family obligation with upward support, and of relationship quality with downward support. Continued support exchanges among very old parents and their children indicated that intergenerational theories still hold up in very late life relationships. Healthcare professionals should be aware that attention to relationship quality and family norms might be vital to ensure that support needs are met.

THE CONNECTION BETWEEN SOCIAL INEQUALITY AND INTERGENERATIONAL TRANSFERS BETWEEN THREE GENERATIONS IN EUROPE

Christian Deindl, *TU Dortmund University, Dortmund, Nordrhein-Westfalen, Germany*

Family members support each other across the entire family cycle. Parents help their adult children with financial transfers and hands-on-support and childcare, while children in mid-life often support their older parents with help and care. However, there is profound social inequalities linked to intergenerational transfers. While there is some research on inequality for some types of intergenerational transfers and some transfer directions, there is still no conclusive study bringing together all different support types between multiple generations from different social backgrounds over time. In our view, taking a longitudinal multi-generational perspective is essential to capture dependencies and negotiations within families from different socio-economic backgrounds within different regional contexts. If middle-aged parents have to take care of their own older parents, they have fewer resources for their(grand-)children, who might then receive less attention and support from them. This may differ according to access to support from public or private institutions. Here, country and regional specifics have a huge impact on support patterns within the family, which can only be captured when looking into developments and change. Using six waves of the Survey of Health, Ageing and Retirement in Europe (SHARE), we look at intergenerational transfers between multiple generations over time across European regions, considering mid-aged Europeans in the

“sandwich” position between older parents and children and include multiple transfer directions and types over time to assess the links between social inequality and intergenerational solidarity in Europe’s ageing societies. The impact of Covid 19 on this issue will also be considered.

THE COSTS OF CONCERN: HEALTH IMPLICATIONS OF WORRIES ABOUT AGING PARENTS AND ADULT CHILDREN

Kelly Cichy,¹ and Athena Koumoutzis,² 1. *Kent State University, Kent, Ohio, United States*, 2. *Miami University, Oxford, Ohio, United States*

As their parents age and their children enter adulthood, midlife adults need to manage their worries and concerns about both generations. In midlife, worries about aging parents’ health and emerging needs for support co-occur alongside worries about adult children’s relationships and prolonged need for support. Research reveals links between midlife adults’ worry and sleep quality, underscoring how worries compromise health and well-being. In addition to compromising sleep, worries may also contribute to poor health behaviors, such as emotional eating. Emotional eating, where individuals eat in response to stressors and negative emotions, is a significant risk factor for overeating and obesity. Less is known; however, about how midlife adults’ worries contribute to poor health behaviors. To address this gap, the current study considers how midlife adults’ concurrent and previous day’s daily worries about aging parents and adult children are associated with daily well-being and health behaviors. Respondents are midlife adults (40-60 years) from Wave II of the Family Exchanges Study (Fingerman et al., 2009). During 7 days of daily telephone interviews, respondents indicated if they worried about their adult children and their aging parent(s), if they ate food for comfort, and their daily negative mood. Controlling for demographics, on days when midlife adults worried about their adult child(ren), they reported more negative emotions than on days without these worries ($p < .05$). Respondents engaged in more eating for comfort the day after they reported worrying about their mother ($p < .05$). Implications for aging families will be discussed.

THE EFFECTS OF SOCIAL SUPPORT ON THE PSYCHOLOGICAL WELL-BEING OF OLDER PARENTS: A LONGITUDINAL STUDY

Erik Blanco, *University of Southern California, Leonard Davis School of Gerontology, Los Angeles, California, United States*

This study examines whether parental support (the provision of social support by older parents to adult children) and filial support (older parents’ receipt of social support from adult children) influence two orthogonal dimensions of older adults’ psychological wellbeing: positive feelings and negative feelings. This study also highlights the importance of accounting for parental need as a mediator of social support. A longitudinal design is used to examine the effects of social support on the psychological wellbeing of older adults at Wave 6 (1998) and Wave 8 (2004) of the Longitudinal Study of Generations. Parental support significantly increases parents’ positive feelings, which suggests that, when it comes to positive feelings, it is better to give support than to receive it. Filial support findings indicate that older adults

with greater level of disability demonstrate a decrease in negative feelings when they received filial support. However, this effect does not hold for older adults with lesser levels of disability, suggesting that, when it comes to older adults’ negative feelings, it is better to receive support (rather than to give it) when parents are in need. Although parental and filial support have the potential to buffer stressful life transitions in old age, most parents wish to remain independent, even in later life, making them reluctant to accept filial support. The parent-adult child relationship is crucial for psychological wellbeing, especially because of increased life expectancy.

THE IMPACT OF LIVING ARRANGEMENTS AND INTERGENERATIONAL SUPPORT ON THE HEALTH STATUS OF OLDER PEOPLE IN CHINA

Yazhen Yang, Maria Evandrou, and Athina Vlachantoni, *University of Southampton, Southampton, England, United Kingdom*

Research to-date has examined the impact of intergenerational support in terms of isolated types of support, or at one point in time, failing to provide strong evidence of the complex effect of support on older persons’ wellbeing. Using the Harmonised China Health and Retirement Longitudinal Study (2011, 2013 and 2015), this paper investigates the impact of older people’s living arrangements and intergenerational support provision/ receipt on their physical and psychological wellbeing, focusing on rural/ urban differences. The results show that receiving economic support from one’s adult children was a stronger predictor for higher life satisfaction among older rural residents compared to those in urban areas, while grandchild care provision was an important determinant for poor life satisfaction only for older urban residents. Receiving informal care from one’s adult children was associated with a poor (I) ADL functional status and with depressive symptoms among older rural people. Meanwhile, having weekly in-person and distant contact reduced the risk of depression among older people in both rural and urban areas. The paper shows that it is important to improve the level of public economic transfers and public social care towards vulnerable older people in rural areas, and more emphasis should be placed on improving the psychological well-being of urban older residents, such as with the early diagnosis of depression.

Session 9265 (Poster)

Family Caregivers' Perceptions and Experiences

A QUALITATIVE ANALYSIS OF FAMILY CAREGIVER PERSPECTIVES FROM THE CAREGIVING TRANSITIONS STUDY

Marcela Blinka,¹ Chelsea Liu,² Orla Sheehan,³ J. David Rhodes,⁴ and David Roth,¹ 1. *Johns Hopkins University, Baltimore, Maryland, United States*, 2. *Harvard School of Public Health, Allston, Massachusetts, United States*, 3. *Johns Hopkins University School of Medicine, Johns Hopkins University, Maryland, United States*, 4. *University of Alabama at Birmingham, University of Alabama at Birmingham, Alabama, United States*

As people live longer, informal caregiving for family and friends is becoming increasingly common. Caregiver satisfaction with their role is now of greater importance to an increasing proportion of the U.S. population. Most research on caregivers has studied convenience samples, often restricted to caregivers of people with dementia. Various studies have examined the impact of caregiving on caregivers' health but to our knowledge there are no qualitative studies of caregiving experiences from caregivers in population-based samples. This study investigated the impact of caregiving on participants who transitioned into a caregiving role while participating in a national population-based study. Participants were from the Caregiving Transitions Study, which is ancillary to the Reasons for Geographic and Racial Differences in Stroke (REGARDS) Study. We thematically analyzed responses from 150 caregivers providing care for multiple different conditions to an open-ended question asked at the time of enrollment and designed to encourage caregivers to share additional details about their caregiving experience. Four major themes were identified: cultural/family expectations; growth opportunities and reciprocity; stressors and challenges; and recommendations. Participants shared both positive and challenging experiences in their role as a family caregiver as well as the impact that these experiences had on their lives. Caregivers shared that one of the most important motivations for taking on this role was their sense of duty toward family. Caregivers also highlighted the positive impact of caregiving on their lives such as opportunities for personal growth, acquisition of new skills, and finding a sense of fulfillment and gratitude.

AN INTEGRATIVE THEORETICAL MODEL TO PREDICT POSITIVE ASPECTS OF CAREGIVING IN DEMENTIA

Doris Yu,¹ Sheung-Tak Cheng,² and Timothy Kwok,³

1. *University of Hong Kong, Hong Kong, Hong Kong,*

2. *The Education University of Hong Kong, The Education University of Hong Kong, Hong Kong,* 3. *The Chinese University of Hong Kong, Shatin, N.T., Hong Kong, Hong Kong*

Family caregiving for dementia is the crucial informal care resource to buffer the associated disease burden. Whereas substantial research focused on ameliorating the caregiving burden through increasing their coping resources, least attention is placed on how to promote their positive aspects of caregiving (PAC). This longitudinal exploratory study aimed at testing Whereas the perceived self-efficacy was further enriched in the context of good social support an integrative theoretical model which attempts to explain the evolution of PAC from the paradigm of stress and coping and existentialism. From June 2017 to April 2020, we have recruited a total of 403 dementia caregivers from the a geriatric clinic in Hong Kong (mean age = 56.2, SD = 12.2; child-caregiver: 73.9%). About 61% of them were taking care of PwD of moderate to severe dementia. Validated instruments were used to measure the hypothesized model constructs. By using path analysis, it was found that PAC was evolved from two conditions, including i) perceived self-efficacy developed through active coping strategies for carers with good to moderate social support and ii) meaning-focused coping in

the context of high religiosity, better social support and active coping. Data-model fit was evident by RMSEA = 0.023, CFI = 0.994, NFI = 0.968 and AIC = 97.762. The findings suggested that PAC was evolved from the interaction of the stress-coping and meaning-making process. Empowering carers for successful caregiving experience, facilitating them to make meaning in the process, enhancing good dyadic relationship and social support are crucial to cultivate PAC.

CAREGIVING ACROSS THE LIFE COURSE: LIFE HISTORY FINDINGS FROM THE HEALTH AND RETIREMENT STUDY (HRS)

Marina Larkina,¹ and Jacqui Smith,² 1. *University of Michigan, Ann Arbor, Michigan, United States,* 2. *University of Michigan, University of Michigan, Michigan, United States*

Informal caregiving, defined as unpaid care provided to a relative or friend with some sort of special need, is a topic of research across different disciplines. Previous research highlights the prevalence and heterogeneity of caregivers in terms of their age, gender, relationship with the care recipient, and the duration of care provision. However, most research focuses on a specific episode of caregiving. Little is known about the people who provide care to multiple recipients throughout their own life. To fill this gap, we examined data from the HRS Spring 2017 Life History Mail Survey (N = 3520; age range 50-101 yrs). Participants reported their relationship with people to whom they had provided unpaid care for ≥ 6 months (max 5) and listed the start and end years of care. Compared with people who had not provided care, caregivers (N = 1000, 28%) were more likely to be women, white, and currently widowed. They cared for their parents (67%), spouses (22%), children (11%), or other relatives (16%) and 30% reported providing care two or more times (M = 1.44, SD = 0.81). Respondents, who reported multiple episodes of caregiving were more likely to be women, widowed, aged between 25 and 50 at the time of first providing care. People who first cared for their spouse were less likely to report multiple caregiving episodes comparing with those who cared for parents or children. Future research will examine the health and well-being consequences associated with caregivers' histories of providing unpaid care to others.

CAREGIVING BETWEEN SPOUSE AND ADULT CHILD CAREGIVERS OF OLDER ADULTS WITH COGNITIVE IMPAIRMENT

Nicole Garcia,¹ Anna Papazyan,² Sarah Choi,³ and Yeonsu Song,¹

1. *UCLA, Los Angeles, California, United States,* 2. *VA Greater Los Angeles Healthcare System,*

California, Los Angeles, California, United States, 3. *University of California, Los Angeles, Los Angeles, California, United States*

Prior studies of caregiving characteristics by type of caregivers are inconsistent, particularly those who are spouses and adult children. This study examined caregiving characteristics between spouses and adult children of cognitively impaired older adults. We analyzed phone-screening data from an ongoing trial of a dyadic sleep intervention program for persons with dementia and their caregivers. Data included spouse caregivers (n=52) and adult child caregivers (n=24). Nearly all participants (95%) lived with their care recipients

(91% with dementia). Types of caregiving activities were measured by activities of daily living [ADLs] and instrumental ADLs [IADLs] with their levels of intensity (0 [total independent] to 3 [total dependent]). Care recipients' sleep was measured by the Neuropsychiatric Inventory-Nighttime Behavioral Subscale (8 items). Analyses included Pearson correlations and t-tests. Adult child caregivers helped their care recipients at significantly higher levels as indicated by their measure of dependence in dressing (1.46 ± 1.22 vs. 0.87 ± 1.16 , $p = 0.044$), continence (1.22 ± 1.38 vs. 0.54 ± 1.04 , $p = 0.021$), laundry (2.87 ± 0.46 vs. 2.13 ± 1.24 , $p = 0.007$), and transportation (3.00 ± 0.00 vs. 2.63 ± 0.79 , respectively; $p = 0.031$) than spouse caregivers. Adult child caregivers also reported their care recipients having more difficulty falling asleep (56% vs. 19%, respectively; $p = 0.004$) and having more numbers of sleep problems than spouse caregivers (3.54 ± 2.08 vs. 2.48 ± 1.51 , respectively; $p = 0.014$). The findings suggest that adult child caregivers may involve higher levels of caregiving responsibilities during daytime and nighttime, compared to spouse caregivers. Further research needs to explore complementary ways to involve spouse and adult child caregivers in the care of this vulnerable population.

DIFFERENT EXPERIENCES OF ADULT CHILD AND SPOUSAL CAREGIVERS WITH FAMILY CONFLICT

Stacy Yun, Kendall Weber, Geffen Ferszt, JoAnna Dieker, and Sara Qualls, *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*,

Previous research indicates that different types of caregivers report distinct levels of family conflict (Dieker et al., 2019). However, as half (52%) of the participants in the previous study did not report family conflict, the purpose of this study was to examine the relationships among types of caregivers, family conflict, and caregiver burden in those who experience family conflict. Participants ($N = 277$; aged 19 to 87; $M = 52.96$) comprised of 197 adult child and 80 spousal caregivers. They completed the Caregiver Reaction Scale (O'Malley & Qualls, 2017) to assess different aspects of the caregiving experience. Hierarchical regressions (block 1: demographics, block 2: family conflict) were computed to predict caregiving burden. For spousal caregivers, the final model explained 2.2% of the variance in caregiving burden, $F(7, 69) = 0.22$, $p = .98$. None of the variables were significant. Additionally, family conflict did not uniquely influence caregiving burden beyond demographics, $F_{change}(2, 69) = 0.03$, $p = .97$. For adult child caregivers, the set of predictors accounted for 20.5% of the variance in caregiving burden, $F(7, 183) = 6.75$, $p < .001$. Having more family beliefs and support conflict predicted greater caregiving burden ($ps < .01$). Family conflict scores also significantly explicated caregiver burden beyond demographics, $F_{change}(2, 183) = 17.60$, $p < .001$. Results suggest that family conflict is a stronger driver of caregiver burden for adult child than spousal caregivers. Findings imply the need for clinicians to target appropriate interventions for adult child caregivers to reduce caregiver burden.

EXAMINING SUBJECTIVE AGING THROUGH THE LENS OF THE CAREGIVER EXPERIENCE

Kristen Hardin-Sigler, Kaitlin Grelle, and Rebecca Deason, *Texas State University, San Marcos, Texas, United States*

Caregivers of individuals with Alzheimer's disease and related dementia (ADRD) often experience burden that has been associated with poor physical and psychological health outcomes (Andren & Elmstahl, 2007; Zimmerman et al., 2018). However, very little research investigates how the caregiving experience may impact an individual's subjective aging experience. Various aspects of subjective aging have been implicated in health outcomes and memory function (Brothers et al., 2017; Stephan, Sutin, Caudroit, & Terracciano, 2016). The purpose of this study was to investigate the differences in perceptions of subjective aging between caregivers and non-caregivers. Participants ($N = 185$) completed a survey assessing several aspects of subjective aging, including subjective age, or how old an individual feels, memory function, well-being, attitudes towards aging, and aging stereotypes. A series of independent t-tests indicated that there were significant differences between groups on subjective age ($p = .013$), and subjective memory function ($p = .013$). Caregivers ($n = 93$) reported feeling significantly older than their chronological age, reported significantly more subjective memory complaints, and also reported poorer subjective memory function when compared to the non-caregiver ($n = 92$) control group. Previous literature does suggest that older subjective age ratings are associated with poor subjective memory function, so these results are not necessarily surprising. However, these results suggest that caregiving for individuals with ADRD may negatively impact caregivers' perceptions of their own aging experience, but not necessarily their perceptions about aging in general.

FAMILY CAREGIVING SUBTYPES IN THE CAREGIVING TRANSITIONS STUDY: A LATENT CLASS ANALYSIS

John Bentley,¹ Carly Lupton-Smith,² and David Roth,³
 1. *University of Mississippi, University of Mississippi, Mississippi, United States*, 2. *Johns Hopkins University, Johns Hopkins University, Maryland, United States*, 3. *Johns Hopkins University, Baltimore, Maryland, United States*

Family caregiving requires activities and experiences that have negative and positive features, producing stress but also providing benefits. The Caregiving Transitions Study (CTS) enrolled 283 caregivers from a national epidemiologic study, of which 32 were caregivers prior to enrollment in the parent study, and 251 became caregivers while participating in the parent study. Telephone interviews were conducted after caregivers provided care for a minimum of 1.6 years (mean = 7.7 years). Latent class analysis (LCA) was used to detect unobserved groups of caregivers. Number of problems (i.e., ADL, IADL, communication, emotional, disruptive behavior), average burden per problem, depressive symptoms, perceived stress, purpose in life, positive aspects of caregiving, hours of care, and duration providing care were used as indicators. Classes were subsequently compared on several external variables, including demographics, quality of life, leisure activities, and caregiving strain. The best-fitting model consisted of three classes (4.6% long-term, 27.6% high-distress, and 67.8% moderate-distress). Classes were similar with respect to sex, age, race, and primary caregiving status of the caregiver. Long-term caregivers had much longer caregiving durations and commonly provided care to a child. The high-distress class was noteworthy in terms of greater

number of experienced patient problems; greater likelihood of caring for a person with dementia; higher levels of caregiving strain, depressive symptoms, perceived stress, and perceived burden; and lower levels of quality of life, purpose in life, positive aspects of caregiving, and leisure activities. These findings suggest that caregivers can be classified into distinct subtypes, with one subtype characterized as experiencing high distress.

OLDER LATINOS' PERCEPTIONS OF THE CAREGIVING EXPERIENCE

Michelle Jaldin,¹ Guilherme Balbim,² Isabela Marques,³ and David Marquez,⁴ 1. *University of Illinois at Chicago, Chicago, Illinois, United States*, 2. *University of British Columbia, Vancouver, British Columbia, Canada*, 3. *Universidade de Sao Paulo, Sao Paulo, Sao Paulo, Brazil*, 4. *University of Illinois at Chicago & Rush University, University of Illinois at Chicago, Illinois, United States*

There has been a rapid growth of Latinos age 65 and older in the United States and the population is projected to grow to 21.5 million by 2060. Latinos with Alzheimer's disease is expected to increase 832% by 2060. Caregiving for adults with Alzheimer's Disease and Related Dementias (ADRD) is physically, emotionally, and financially demanding, and has significant implications for caregivers' health, personal and social life, and overall well-being. This study aimed to describe the perceived experiences of middle-aged and older Latino who were primary caregivers of relatives with ADRD. We conducted semi-structured interviews with Latino caregivers to examine their perceived experiences of providing care for a relative with ADRD. Interviews were conducted in English and Spanish and were transcribed, translated into English when needed, and coded. We conducted direct content analysis. Participants were aged 50 to 75 years ($n = 16$), the majority were female ($n = 12$), and majority were caring for either their parent or spouse. We identified six reoccurring themes in the Latino caregiving experiences: (1) caregiver burden; (2) dealing with care recipient; (3) coping strategies; (4) social support; (5) cultural values; and (6) knowledge about services. The identified themes showed that Latino caregivers need support from their family and friends for caregiving. Latino family's structure plays an important role in caregiving experience. These themes are important to consider in future interventions that aim to reduce caregiver burden in Latinos as they influence the overall well-being of the caregiver.

PERCEIVED APPRECIATION FOR CARE ASSOCIATES WITH HIGHER QUALITY CAREGIVING DAY-TO-DAY

Kylie Meyer,¹ Arielle Chinae,² Sara Masoud,² Kevin Hamilton,² Ashlie Glassner,² Jing Wang,³ and Carole White,² 1. *UT Health Sciences at San Antonio, San Antonio, Texas, United States*, 2. *UT Health San Antonio, San Antonio, Texas, United States*, 3. *University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States*

Family members are critical to dementia care and the U.S. long-term services system. Yet, little is known about how to support the quality of care provided by family members, who often receive little training. We hypothesize that on days when caregivers feel more appreciated, they report

providing a higher quality of care. To test this hypothesis, we asked spousal dementia caregivers ($N=21$) to complete 14 daily surveys that asked about their daily caregiving experiences. Our measure for "quality of care" was based on the Exemplary Caregiving Scale, and included 3-items pertaining to provision of care (e.g., "You considered your spouse's wishes and opinions when providing assistance"). Response options included "Most of the time," "Some of the time," and "Never"; scores were summed (range 0 to 6). Caregivers were also asked to what extent their spouse appreciated the care provided ("Not at all," "Some," or "A lot"). We applied multi-level mixed models to the data, and controlled for age, gender, Hispanic ethnicity, number of behavioral symptoms of dementia each day and months since diagnosis. In adjusted models, we found that on days when caregivers believed care recipients appreciated care provided "Some" or "A lot," they reported providing higher quality care ($B=0.52$, $p=0.010$ and $B=0.79$, $p<0.001$, respectively) compared with days when caregivers believed care recipients appreciated care provided "Not at all". Preliminary results may inform programs to support caregivers' ability to provide high quality care (e.g., by helping caregivers to perceive rewards) and to identify caregivers at risk of providing low-quality care.

RESEARCH PARTICIPATION AMONG COMMUNITY DWELLING DEMENTIA CAREGIVERS: REFLECTIONS AND SUGGESTIONS

Kiana Cruz,¹ Sama Joshi,² Taeyoung Park,² M. Carrington Reid,¹ Keela Herr,³ Karl Pillemer,² and Catherine Riffin,⁴ 1. *Weill Cornell Medical College, New York, New York, United States*, 2. *Cornell University, Ithaca, New York, United States*, 3. *University of Iowa, Iowa City, Iowa, United States*, 4. *Weill Cornell Medical College, London, England, United Kingdom*

Clinical trials for dementia caregivers have suffered from small sample sizes that lack adequate power to detect treatment benefits. Addressing these methodological shortcomings is contingent upon successful recruitment and enrollment of caregiver participants, but major barriers impede their participation in research. This presentation describes the lessons learned from recruiting and enrolling dementia caregivers into a pilot randomized controlled trial designed to help caregivers recognize and communicate about pain in dementia care recipients. Using Bronfenbrenner's ecological model, we organize our discussion of challenges and opportunities into three levels: community (ecosystem), institution (microsystem), and individual. A key challenge at the community level was gatekeeping by organization leaders, including those from support groups, senior centers, and congregate living facilities. At the institutional-level, challenges included an absence of administrative mechanisms for identifying caregivers and a lack of caregiver research expertise on the Institutional Review Board. At the individual-level, challenges included time constraints and varying motivations for participating in research. Strategies for overcoming these challenges spanned the three levels and included establishing trust and rapport with various constituencies; adapting our recruitment approaches to meet the specific motivations of prospective participants; and refining recruitment scripts to allow for greater personalization. Employing these strategies, which can be generalized to recruit other hard-to-reach

populations, helped to overcome recruitment challenges and expedite enrollment of caregivers from a diverse range of sociodemographic backgrounds. Further improvement will require coordinated changes at the institutional and community levels, including the development of central research registries and administrative mechanisms for identifying caregivers.

ROLE-REVERSALS IN CAREGIVING: CASE STUDIES OF TWO WOMEN LIVING WITH LATE STAGE CANCER

Candice Reel,¹ J. Hunter Williams,¹ Emma Brennan,¹ Jonna Williams,¹ Kristen Payne,² and Rebecca Allen,² 1. *The University of Alabama, Tuscaloosa, Alabama, United States*, 2. *University of Alabama, Tuscaloosa, Alabama, United States*

Many studies have examined the effects of caregiving burden and many others have focused on the effects of having a caregiver (Haynes-Lewis et al., 2018; Trevino, Prigerson, & Maciejewski, 2018; Semere et al., 2020). However, there is little data on the experience of role reversal, once responsible for caring for others and now being cared for while living with cancer. This project aims to identify ways in which women living with cancer cope with the internal struggles of receiving care. The current project is a case study of two females, one age 67, NHW, with a breast cancer diagnosis and one age 60, Black, with an ovarian cancer diagnosis, who once were caregivers and are now being cared for by family. Two semi-structured interviews were conducted that were approximately 60 minutes each. The study data are from a larger project focused on the self-perception of older women with late-stage cancer. Four independent researchers used thematic analysis to uncover common themes of coping between the two women receiving care. The themes uncovered were acceptance of the loss of autonomy, positive death attitudes, good relationships with their caregivers, and religiosity were identified and coded as coping strategies. The qualitative data showed that the use of these coping strategies helped the women be more accepting to care with less internal conflict. Future research should focus on generalizing these findings on a larger sample and use the data to help cancer patients better accept care from others.

THE LIFE SATISFACTION OF INFORMAL CAREGIVERS IN EUROPE: REGIME TYPE, INTERSECTIONALITY, AND STRESS PROCESS FACTORS

Sean Browning, *University of Victoria, Victoria, British Columbia, Canada*

This research assessed the role of welfare state/family care regimes, intersecting social locations and stress process factors in influencing the life satisfaction of informal caregivers of care recipients with age-related needs or disabilities within a European international context. Empirical analyses were conducted with a sample of informal caregivers residing in Denmark, Sweden, France, Germany, Italy, Greece and the United Kingdom (n=6,007). Ordinary least squares and ordered logit regression models revealed that welfare state/family care regime, intersecting social locations, and stress process factors were independently associated with the life satisfaction of informal caregivers. Furthermore, there was

some evidence to suggest that social location and stress process factors intervened in some of the relationships between regime type and life satisfaction. There was also some evidence that stress process factors intervened in the relationships between social location factors and life satisfaction. Overall, the results provide support for integrating welfare state/family care regime type and intersectionality factors into the stress process model as applied to the context of informal caregiving. The results also have policy and practice implications with regards to which social location and stress process factors explain specific disparities in life satisfaction between informal caregivers residing in different welfare state/family care regimes.

THE OTHER CAREGIVERS: INFORMAL NON-SPOUSAL MALE CAREGIVERS FOR PERSONS WITH DEMENTIA

Gretchen Tucker, *University of Maryland, Baltimore, Columbia, Maryland, United States*

Informal caregivers for persons with Alzheimer's disease and related dementias (ADRD) have become an integral part of the long-term health care system. They are relied on to provide day-to-day care that is challenging, complex, and often spans several years. Most of the research on informal caregivers for persons with ADRD have focused on spousal caregiving, mother-daughter dyads, and daughters. There is sparse literature on informal non-spousal male caregivers for persons with ADRD. The objective of this research was to obtain an understanding of the experiences of informal non-spousal male caregivers for persons with ADRD. This descriptive qualitative pilot study consisted of in-depth one-on-one interviews with three informal non-spousal male caregivers for persons with ADRD. Four themes emerged through data analysis: 1) the male perspective and experience of caregiving, 2) relationship dynamics, 3) caregiving challenges, and 4) finding meaning within caregiving. Conclusion: Similar to other caregivers, informal non-spousal male caregivers assisted with transportation, managing medical appointments, as well as bathing and personal care. Differences with other caregivers, specifically female caregivers, emerged in terms of descriptions of traditional versus non-traditional gender roles. The implications of this study are that public policies, support services and medical professionals need to understand and be able to address the different experiences and needs of informal non-spousal male caregivers.

THE SHAPE OF CARE: PATTERNS OF FAMILY CAREGIVING AMONG CHINESE ADULTS IN THE MIDDLE TO LATER STAGE OF LIFE

Haoshu Duan, *University of Maryland, Arlington, Virginia, United States*

Due to the lack of institutional support, families have long been the primary caregivers in China. Most studies to date only focused on one single care activity during a particular life course stage. Nonetheless, older adults today are more likely to care for multiple family members concurrently or sequentially (serial caregivers). The studies on discrete snapshots of care activities failed to capture the patterns of family caregiving overtime. Utilizing four waves of longitudinal data from CHARLS (2011-2018, N=17,039), this study particularly focuses on care activities to grandchildren, parents, and

spouse, and maps out the family caregiving patterns overtime. Using latent profile analysis, this study identifies five family caregiving patterns: 1). Light grandchild caregivers (27%), who on average provided 4.3 years' grandchild care mostly; 2). Heavy grandchild caregivers (11%), who on average on provided 7 years' grandchild care mostly; 3). Light caregivers for grandchildren and parents (7%), who sequentially provided 1-year care to grandchildren and parents; 4). Heavy serial caregiver (6%), who mostly provided care to spouse and grandchildren with higher overlapping years; 5). Overall light caregivers (49%), who on average provided less than one year of care to any recipient. The preliminary results suggest that heavy serial caregivers (6%) far worst in terms of depressive symptoms and more likely to report worsened self-rated health; and overall light caregivers (49%) have the lowest depressive symptoms and more likely to report good self-rated health.

Session 9270 (Poster)

Family Caregiving (HS Poster)

AGING IMMIGRANT FAMILY CAREGIVERS HEALTH, SOCIAL ENGAGEMENT, AND HEALTH LITERACY

Mary Dioise Ramos, *Kennesaw State University, Kennesaw, Georgia, United States*

Family caregiving is evolving in multiple ways. There is an increasing recognition of the role of informal or unpaid family caregivers. Extensive body of research shows that family members who provide care to individuals with chronic or disabling conditions are themselves at risk. However, most evidence on family caregiving gear towards Caucasian middle-class populations. There is limited research that exists about aging immigrant family caregivers who are ill-prepared for their role and provide care with little or no support. The specific aim of this study was to assess and determine the association of health status, social engagement, and health literacy among aging immigrant family caregivers. This study utilized a non-experimental, cross-sectional, correlational design. Most of the participants are female married Asian women, who are retired, living with their spouses, and taking care of their family members more than 4 hours a day with Alzheimer's, Parkinson's, and cardiovascular disorder. Most participants have existing medical condition such as hypertension, diabetes, high cholesterol, and heart disease. Most participants experienced problem with sleep and difficulty falling asleep. While some participants experienced fatigue and having trouble doing regular leisure activities with others. There is an association between sleep disturbance and ability to participate in social roles and activities among aging immigrant family caregivers. Inclusion of people from different ethnicities, backgrounds, and socioeconomic position in caregiver research is vitally important. There is a need for a greater understanding of the contextual factors of family caregiving and recognizing the prevalence and characteristics of aging immigrant family caregivers.

EXHAUSTED AND TRAPPED IN ISOLATION. CARING FOR A SPOUSE WITH DEMENTIA DURING THE COVID-19 PANDEMIC

Lena Hammar,¹ Marcus Johansson,² Lena Dahlberg,² Kevin J McKee,² and Martina Summer-Meranius,³

1. *Mälardalen University / Dalarna University, Västerås, Vastmanlands Lan, Sweden*, 2. *Dalarna University, Falun, Dalarnas Lan, Sweden*, 3. *Mälardalen University, Västerås, Vastmanlands Lan, Sweden*

Even before the Covid-19 pandemic, spouse carers of persons with dementia (PwDs) found their care responsibilities overwhelming and had little time to focus on their own lives. To minimize the risk of being infected with Covid-19, older persons are recommended to self-isolate in their homes, while formal support such as respite care and day care centers are withdrawn. This study involved semi-structured interviews with 24 spouse carers of community-living PwDs, with the aim of describing their situation during the pandemic. The interviews were analyzed with qualitative content analysis. Results revealed that they commonly declined help because of the perceived risk of their spouse being infected with Covid-19 and thus also possibly causing their death. They described feelings of being trapped in their situation, as they experienced having no choice than take all responsibility for the care of their partner themselves, with cost of being unable to take necessary breaks. This was described as making an already strained situation almost unbearable, which led to conflicts with their partner. However, the spouses also described positive aspects due to strategic changes in health and social care provision to prevent the spread of the virus, such as greater staff continuity in home care services, and patient transportation service. These made the PwD less stressed and influenced their everyday life positively. It could be concluded that the extent burden during the Covid-19 pandemic calls for extensive development of tailored support to better tackle the rapid changes that can occur in a society.

FAMILY ADVOCACY FOR RESIDENTS IN NURSING HOMES DURING THE COVID-19 PANDEMIC

Cristina de Rosa, Yanjun ZHou, Amy Lyons, and Yu-Ping Chang, *University at Buffalo, Buffalo, New York, United States*

To protect one of the most vulnerable populations from COVID-19, nursing homes enacted and enforced visiting restrictions and other measures to limit the spread of this communicable disease. Family members, many of whom are former caregivers, were suddenly cut off from nursing home residents, and struggled to maintain connection with their loved ones residing in nursing homes. The purpose of this study was to describe the experiences of family members of residents in nursing homes in advocating for residents and themselves during a time of uncertainty and many challenges. This study used a qualitative descriptive approach to conduct individual interviews. Ten family members of residents of two nursing homes in a Northeastern state were interviewed by phone or videoconference using a semi-structured guide. Interviews were transcribed verbatim and analyzed using Braun and Clarke's Reflexive Thematic Analysis. Family members expressed concerns for the lockdown's impact on residents' psychosocial wellbeing in addition to the potential physical dangers of COVID-19. They explored creative means of meeting needs for information and interaction, but often felt that these efforts fell short of replicating the connectedness of in-person visits. Family members identified multiple missed opportunities for involvement in care, and voiced willingness to comply with infection prevention guidelines, such as maintaining distance, to be present with

residents. Our findings indicate that family members advocated for residents' interests to ensure quality care. Future research and policy should consider family members as a potential resource for providing care and companionship during times of crisis.

FAMILY CAREGIVER BURDEN OF MEDICATION ADMINISTRATION FOR OLDER ADULTS ADMITTED TO HOME HOSPICE

Jennifer Tjia,¹ Margaret Clayton,² Jennifer Smith,² Olivia Wood,³ Susan Hurley,³ Geraldine Puerto,⁴ Vennesa Duodu,⁴ and Susan DeSanto-Madeya,⁵ 1. *UMass Chan Medical School, University of Massachusetts Medical School, Massachusetts, United States*, 2. *University of Utah, The University of Utah, Utah, United States*, 3. *Care Dimensions, Care Dimensions, Massachusetts, United States*, 4. *UMass Medical School, UMass Medical School, Massachusetts, United States*, 5. *University of Rhode Island, University of Rhode Island, Rhode Island, United States*

OBJECTIVE To characterize FCG burden of medication administration for older adults in home hospice. **METHODS** Pilot clinical trial of a hospice-staff level communication and medication review program to facilitate goal-concordant prescribing, including deprescribing, for older adults in home hospice. Patients newly admitted to hospice were eligible if ≥ 65 years, prescribed ≥ 5 medications and had a FCG. Exclusion criteria included being non-English speaking or having a Palliative Performance Score < 40 . Measurements include 24-item FCG Medication Administration Hassle Scale (range 0-96) at hospice admission and at 2-, 4-, 6-, 8-weeks and monthly until death. Descriptive statistics characterize baseline FCG Hassle score. **RESULTS** In this actively recruiting study, $n=9$ patient-caregiver dyads are enrolled to date. Mean patient age is 80.6 years (range 69-101). Of 9 caregivers, 7 were female, 5 children, and 3 spouses. The majority (67%) of caregivers were extremely involved in medication management. Mean FCG Hassle Score = 17.1 (SE 5.9; range 2-58), and differed between spouses (mean = 5 [SE 1.7; range 2-8]) and children (mean = 31.4 [SE 9.53; range 3-58]). The highest burden concern was recognizing medication side effects, followed by feeling comfortable making medication decisions, arguing with the care-recipient about when to take medications, knowing why a medication is being given and whether it is effective, and knowing when to hold, increase, decrease a dose or discontinue the medication. **CONCLUSION** FCGs of older adults in home hospice report different levels of medication administration hassle depending on their relationship to the patient. The most bothersome concern is recognizing medication side effects.

FRAUDULENT DATA DETECTION AND PREVENTION WITHIN THE NATIONAL CAREGIVER SURVEY

Jada Jackson,¹ Jessica Lipchin,¹ Rachel Zhang,² and Sheria Robinson-Lane,¹ 1. *University of Michigan School of Nursing, Ann Arbor, Michigan, United States*, 2. *College of Engineering, University of Michigan Ann Arbor, University of Michigan Ann Arbor, Michigan, United States*

The National Caregiver Survey is an online, incentivized survey that aims to gather information about the health and coping strategies used by Black family caregivers of persons with dementia. The survey data will help elucidate

the relationships between coping, health, and adaptation to family caregiving and facilitate the development of culturally responsive caregiver support programming. Virtually distributing this survey made it cost-effective, easily accessible, and quick to produce usable data. The online format also helped the team reach caregivers from across the nation, as well as keep participants safe during the COVID-19 pandemic. Unfortunately, because online surveys are advertised and administered digitally, they become targets for hacking, especially when the surveys are incentivized. The hacking attempts are executed through digital survey bots and threaten the integrity of the collected data. These corrupt responses also increase study costs by falsely rewarding the hackers for their survey responses and research team time in the investigation, detection, and removal of fraudulent responses. To detect potential bots, a reCAPTCHA bot system was incorporated into the survey, and survey questions were formatted specifically to thwart hacking attempts. Finally, data were cleaned to remove illogical, inconsistent, and duplicative surveys. Findings from this work may help researchers improve online survey design and data collection methods to provide greater confidence in conclusions drawn from virtually surveyed data.

GENDER DIFFERENCES IN THE LINK BETWEEN INFORMAL CAREGIVING AND SUBJECTIVE WELL-BEING

Aeri Kim, and Kyungmi Woo, *Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Despite existing evidence on the negative association between informal caregiving and caregiver's well-being, three important knowledge gaps remain. First, the link warrants further scrutiny due to the possibility of individual heterogeneity. Second, less is known about how informal caregiving is related to caregiver's well-being. Third, there is little consensus in the literature regarding whether caregiver's gender matters. This study fills these gaps in the literature. Using seven waves of a large-scale, nationally representative longitudinal study of older adults in Korea between 2006 and 2018, this study employed generalized estimating equations models with a lagged dependent variable as well as fixed effects models. Findings from both models revealed that informal caregiving is negatively associated with subjective well-being, and this association is largely driven by female caregivers. To explore potential mechanisms undergirding this association, we examined the mediating roles of a number of health behaviors. We found that engaging in informal caregiving is associated with a reduction in regular exercise. Results from mediation analyses, however, suggested that regular exercise explains only a moderate amount of the observed association (12% for health-related life satisfaction and 8% for self-rated health). While informal caregiving is obviously a rewarding role, it poses a serious threat to caregiver's well-being. Findings of this study on gender differences in the well-being consequences of informal caregiving lend support to taking a gender-conscious approach in programs aiming to improve the well-being of informal caregivers.

HOW FREQUENTLY ARE CAREGIVERS INCLUDED IN PATIENT EDUCATION FOR ONCOLOGY PATIENTS?

Beth Fields, and Anne Mueller, *University of Wisconsin-Madison, Madison, Wisconsin, United States*

A growing body of literature shows that family and unpaid caregivers of older adults with cancer are assuming more care responsibilities, especially after discharge from an inpatient admission, and frequently report feeling unprepared to do so. Interprofessional collaborative practice can rectify this gap to help ensure caregivers are included in the care team and patient education in the hospital. This retrospective data analysis of electronic health record data examines the prevalence of caregiver involvement in education activities conducted by health care practitioners for older adult cancer inpatients at an academic medical hospital in the midwestern United States. Our dataset includes a total of 676 admissions of older adult cancer inpatients (565 unique patients) between 9/1/2018 and 10/1/2019. Descriptive statistical analyses were conducted to determine the prevalence of caregiver involvement in patient educational activities. The average patient was 75 years old (range: 66-89), white (95%) and male (57%). Approximately 5,720 educational topics were discussed with patients, and 88% of admissions included some patient education. Caregivers were included in 29.6% of educational topics discussed and at least one education session for 42.9% of all admissions. Caregivers are important collaborators in supporting the health and well-being of older adults with cancer, but they are often not included in patient educational activities prior to discharge. Practitioners may need to evaluate barriers to including caregivers in patient education activities. A better understanding of this gap in education can help inform future interprofessional collaborative practice initiatives.

INFORMAL CAREGIVERS' PERCEPTIONS OF BURDENS AND BENEFITS PREDICT GREATER CONFIDENCE IN THEIR ABILITIES

Cristina de Rosa,¹ Rebecca Lorenz,¹ and Suzanne Sullivan,²
 1. *University at Buffalo, Buffalo, New York, United States,*
 2. *University at Buffalo, University at Buffalo, New York, United States*

Informal caregivers experience both burdens and benefits from caregiving. This analysis aimed to determine whether caregiver perceptions of burdens and benefits predicted feelings of confidence in their abilities. In the National Study of Caregiving (NSOC) Round II (2015), we identified 1,390 caregivers as "primary" for providing the greatest number of care hours in the past month to individuals age 65 and over. Logistic regression was performed to assess the influence of primary caregivers' gender, age, relationship to their care recipients, and self-reported indications of burdens and benefits on the odds that they would report confidence in their abilities. Caregivers were more likely to report confidence in their abilities when caregiving taught them to deal with difficult situations (OR=5.93, 95% CI [4.67, 7.54]), gave them satisfaction that their care recipient was well cared for (OR=1.97, 95% CI [1.26, 3.04]), and when caregiving brought them closer to their care recipient (OR=2.61, 95% CI [2.02, 3.36]). Caregivers were less likely to feel confident if they reported frequent changes in routine (OR=.78, 95% CI [.64, .96]). The final model predicted confidence (chi-square = 525.383 [4] $p < .001$) and correctly classified 78.7% of cases. All other variables were non-significant. These findings suggest that confidence in abilities is influenced by caregivers' perception of learning to handle difficult

situations, satisfaction, closeness to the recipient, and burdens associated with changes in routine. Future research should further explore burdens and benefits of caregiving. Health care providers should routinely assess caregivers and provide referrals for additional resources.

PATIENT AND CAREGIVER SYMPTOM TRAJECTORY: THE LAST 2 MONTHS OF CANCER HOME HOSPICE

Maija Reblin,¹ Eli Iacob,² Djin Tay,² Miranda Jones,² Kristin Cloyes,³ Anna Beck,⁴ Kathi Mooney,² and Lee Ellington,²
 1. *Moffitt Cancer Center, Tampa, Florida, United States,* 2. *University of Utah, Salt Lake City, Utah, United States,* 3. *University of Utah, Portland, Oregon, United States,* 4. *Huntsman Cancer Institute, Salt Lake City, Utah, United States*

Patient symptom management is a fundamental goal of cancer home hospice care. However, informal family caregivers, who are primarily responsible for daily patient care, also experience negative symptoms, especially at the end of the patient's life. While research has attended to patient symptom progression in home hospice, little research focuses on caregiver symptoms. To address this, we examined the frequency of both patient and caregiver symptoms to determine how these symptoms change in the last two months of the patient's life. Sixty-three cancer hospice caregivers from 4 US states prospectively reported daily patient and caregiver symptoms via an Interactive Voice Response phone system. We analyzed data from up to the last 60 days of the patient's life. Most caregivers were female (71.4%), Caucasian (88.9%), spouses of the patient (46%); average age was 59 years old (SD=13). Patients were mostly female (54%), with diverse solid tumor cancer diagnoses, and 72 years old (SD=11) on average. Most commonly reported moderate-to-severe patient symptoms were fatigue (67%), pain (47.5%), and loss in appetite (42.3%). Most common moderate-to-severe caregiver symptoms were fatigue (57.8%), trouble sleeping (45.1%), anxiety (52%), and depression (40.4%). Patient and caregiver symptoms were significantly correlated (Pearson $r = .51$, $p < .001$). Mixed-effects models found that both patient and caregiver symptoms (collapsed by week) worsened as patient death approached ($ps < .01$). Researchers and clinicians who are aware of the strong relationship between patient and caregiver symptoms are best able to address caregiver symptoms as part of hospice care, particularly as patient death approaches.

PERCEIVED LIFE MEANING AND PURPOSE AND ITS ASSOCIATION WITH MENTAL AND PHYSICAL HEALTH AMONG FAMILY CAREGIVERS

Yu-Ping Chang,¹ Lorelee Sessanna,¹ and Young Sik Seo,²
 1. *University at Buffalo, Buffalo, New York, United States,* 2. *Roswell Park Comprehensive Cancer Center, Buffalo, New York, United States*

Evidence suggests that having a sense of life meaning and purpose is related to physical health. However, the association between life meaning and purpose and physical and mental health among family caregivers remains unclear. This study aimed to examine whether family caregivers' perceived life meaning and purpose was associated with their physical and mental health (depression and anxiety). The National Study of Caregiving (NSOC) III cross-sectional survey (2017,

N = 2,652) was utilized. One item was used to measure family caregivers' perceived life meaning and purpose and two composite variables were generated to measure depression and anxiety. Physical health was assessed by questions including pain, breathing problems, limited arm/leg strength, low energy, and sleep problems. Weighted logistic regression analyses with covariate adjustments (i.e., caregiver's age, sex, and race/ethnicity) were conducted to examine the association among family caregivers' perceived life meaning and purpose, mental and physical health. Results indicated that family caregivers' perceived life meaning and purpose was associated with a lower probability of having depressive symptoms (OR, .29, 95% Confidence Interval [CI], .15, .57) and anxiety (OR, .43, 95% CI, .23, .79). Furthermore, perceived life meaning and purpose was associated with a lower probability of having breathing problems (OR, .50, 95% CI [.25, .99]). Findings suggest that having a strong sense of life meaning and purpose is linked to better mental health and physical symptoms. Further research is needed to determine the mechanism regarding how life meaning and purpose may improve mental and physical health among family caregivers.

PROLONGED MECHANICAL VENTILATION AT HOME VERSUS LONG TERM CARE: CAREGIVER CHARACTERISTICS AND STRAIN

Esther-Lee Marcus,¹ Jeremy Jacobs,² and Jochanan Stessman,³ 1. *Herzog Medical Center, Herzog Medical Center, Yerushalayim, Israel*, 2. *Hebrew University of Jerusalem, Jerusalem, Yerushalayim, Israel*, 3. *Hadassah Hebrew University Medical Center, Clalit Health Services, Yerushalayim, Israel*

Although the number of Prolonged Mechanical Ventilation (PMV) patients and their informal caregivers (CGs) is rising both at Home or Long Term Care (LTC), little is known concerning CG characteristics or strain. We enrolled 120 patients and 106 informal CGs: 34/46 and 72CGs/74 PMV patients from Home Hospital and LTC respectively. CGs were married (82%), female (60.4%), mean age 59 ±14 years; spouses (29%) or children (40%) of the PMV patient. The 13-item Modified Caregiver Strain Index (MCSI) (Maximum severity=26) was 13.6± 6.5, similar at Home vs. LTC (14.3±7.5 vs. 13.3±6.0, p=0.9). Most frequent complaints were distress concerning patient's changes (93%) or upsetting behaviours (82%), feeling overwhelmed (82%), sleep disturbance (69%) and emotional adjustments (67%). Home CGs reported significantly more physical and financial burden, confinement, and need for work adjustment, while LTC CGs reported greater emotional disturbance and upsetting patient behaviours. Hierarchical clustering identified three clusters of CG strain: burden (physical/time/financial), emotional (upsetting adjustment/ behaviours/overwhelmed) and disturbance (work/plans/confinement). Emotional strain was most frequent, irrespective of site of care; however CGs at Home vs. LTC experienced significantly higher burden and disturbance vs. higher emotional strain respectively. In multivariate models, after adjusting for numerous patient and CG variables, increasing CG strain was consistently associated with rising patient symptomatology. This relationship was pronounced among CGs of Home PMV patients, with a significant interaction variable of Home*Patient symptomatology. Our findings identify specific patterns of strain

among caregivers of PMV patients whether at home or LTC, and highlight the importance of addressing their unique needs.

SUPPORT NEEDS AS PERCEIVED BY GRANDPARENT-CAREGIVERS: A QUALITATIVE SYSTEMATIC REVIEW

Schola Matovu,¹ Deborah Whitley,² and Heather Young,³ 1. *University of Utah College of Nursing, Salt Lake City, Utah, United States*, 2. *Georgia State University, Atlanta, Georgia, United States*, 3. *University of California Davis, Sacramento, California, United States*

Caregiving can have adverse mental and physical health outcomes. Older grandparents who are primary caregivers for their grandchildren report multiple health conditions such as depression, anxiety, hypertension, cardiac disease and chronic fatigue, which are caused by or otherwise exacerbated by the caregiving demands. We conducted this qualitative systematic review to identify support needs that contribute to such poor health outcomes and as perceived by grandparent-caregivers for minor grandchildren. We searched relevant databases (PubMed, PsychINFO, CINAHL, and Social Work Abstracts) using terms such as: child rearing, parenting, child custody, grandparents, support needs, and caregiving. Studies were included for review if they were written in the English language; used only qualitative methods; and were published from January 1990 to January 2020. Included studies were critically appraised using the Critical Appraisal Skills Programme checklist. Data were extracted from these studies and synthesized using meta-ethnography. Of the 2828 studies identified, 58 studies from 12 countries met all inclusion criteria for review. Three main themes emerged from the review: 1) grandparent-caregivers' personal needs, and 2) grandchildren needs. Both themes were further divided into subthemes of health (mental & physical), financial, social (interpersonal, cultural and environmental factors and services). Findings from this review have potential to: 1) inform design of comprehensive interventions and screening needed to address perceived support needs; and 2) identify gaps in and barriers to available support resources for older grandparent-caregivers. Further research is needed on comprehensive assessment of support needs and risk for poor health outcomes among grandparent-caregivers.

TESTING PREDICTIVE FACTORS OF DEPRESSIVE SYMPTOMS AMONG GRANDPARENTS UNDER THE COVID-19 PANDEMIC

Yuqin Jiao, and Christine Fruhauf, *Colorado State University, Fort Collins, Colorado, United States*

An estimated 69.5 million Americans are reported to be grandparents. Among them, about 10% are raising grandchildren and the number of grandparents who are raising grandchildren (GRG) is increasing. Previous research on GRG suggests that the unexpected caregiving duties may lead to negative physical and mental health including more depressive symptoms when compared to non-caregiving grandparents (NGRG). Additionally, grandparent-grandchild relationships determined by emotional availability (EA) of the grandparent may be impacted. These factors might further be complicated, especially as it relates to the health and well-being of GRG, as a result of the COVID-19 pandemic. Thus, the overarching goal of this presentation is to use the

biopsychosocial model to present a conceptual framework to test the mental well-being of GRG during the COVID-19 pandemic. In this presentation, we will 1) summarize appropriate literature on GRG; 2) share a COVID-19 health and well-being assessment survey designated for GRG in order to assess their health before and since the COVID pandemic; and 3) propose a conceptual model to investigate and test the protective role of physical activity and GRG's EA in the grandparent-grandchild relationship for the mental health of GRG. In our model, we argue that GRG experience more COVID-19 pandemic-related stress and more depressive symptoms when compared to NGRG. This proposed conceptual model offers one way to test the predictors of depressive symptoms on GRG. Future testing has the potential to shed new light on the development of appropriate intervention programs tailored to maintain the mental health of GRG.

THE ASSOCIATION BETWEEN CAREGIVER EDUCATION ON ADULT T2DM AND PATIENT'S OUTCOMES IN COMMUNITY: A SYSTEMATIC REVIEW

Aluem Tark,¹ Jiyoun Song,² Jeong-Yeon Kim,³ So Yeon Park,³ and Kyungmi Woo,³ 1. *University of Iowa, University of Iowa, Iowa, United States*, 2. *Columbia University, Columbia University, New York, United States*, 3. *Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Introduction Adult type 2 diabetes (T2DM) threatens public health and most patients manage their diabetic condition while in the community. As it is challenging for patients to properly manage diabetes alone, caregiver involvement in T2DM patient care is encouraged. This study aimed to examine the association between caregiver involvement in T2DM education within a community and the patients' diabetes care outcomes (e.g., glycated hemoglobin (HbA1c) level, behavior, or hospitalization). **Methods** The available scientific literature in PubMed, Cochrane, EMBASE, and CINAHL was searched. The methodological quality of bias was assessed using the Cochrane risk of bias tool. **Results** A total of 13 out of 741 published studies were synthesized in this review. There is evidence that caregiver involvement in T2DM education is effective in the reduction of HbA1C and BMI, but not necessarily effective in reducing lipids. Study results indicate that caregiver related interventions can significantly improve patient diabetes knowledge, physical activity, and self-efficacy, but results were more mixed regarding medication adherence. Risk of bias analysis classified the majority of studies (77%) to be moderate or high quality. **Conclusion** This review aimed to explore the association between caregiver involvement in adult T2DM education in the community and patients' diabetes care outcomes. The findings show an improvement in biological and behavioral self-management outcomes with caregivers involved in T2DM education, though no studies examined the direct association between complications or hospital readmission. Future research focused on tailored interventions and longer follow-up of patient outcomes are recommended.

THE EXPERIENCES OF FAMILY CAREGIVERS OF COMMUNITY-DWELLING OLDER ADULTS WITH DEMENTIA IN PROVIDING DAILY ORAL CARE

Abby Hellem, Kexin Zhou, Xi Chen, Jirakate Madiloggovit, Jennifer Nguyen, Rebecca Morris,

and Sato Ashida, *University of Iowa, Iowa City, Iowa, United States*

Individuals with dementia increasingly rely on caregivers for daily oral care over time. This study explored the experience of family caregivers of community-dwelling individuals with dementia in providing oral care and their interest in caregiver oral education using the concepts of Social Cognitive Theory. Twenty-three caregivers ages 19-80 participated in a semi-structured qualitative interview that also included a structured questionnaire. Majority of caregivers were female (83%) with an average age of 56 years; 29% were spouses. Fifty-four percent of care recipients had natural teeth only, 42% had teeth and dentures, and 4% had dentures only. Caregivers were generally knowledgeable about the importance of oral health, but some expressed a lack of knowledge in how to perform oral care for others. Caregivers reported high levels of outcome expectation, agreeing that providing oral care would improve care recipient's oral health. Caregivers expressed mixed levels of self-efficacy; many cited reduced self-efficacy due to resistance or refusal of care. Quantitative data showed that higher confidence in knowledge and oral care skills was associated with greater confidence in providing oral care ($r=0.726$, $p<0.001$). Intent to participate in a caregiver oral health education program was associated with positive outcome expectations ($r=0.73$, $p=0.007$) and desire to learn the signs and symptoms of mouth pain and infection ($r=0.72$, $p=0.009$). Increasing family caregiver's oral health knowledge and skills, outcome expectations, and self-efficacy to provide care may help improve the oral health of persons with dementia. Additional qualitative and quantitative data and implications for practice will be presented.

USE OF ACTIGRAPHY ON SLEEP OUTCOMES FOR DEMENTIA FAMILY CAREGIVERS: AN INTEGRATIVE REVIEW

Eunae Ju,¹ Melissa Pinto,¹ and Jung-Ah Lee,² 1. *University of California Irvine, Irvine, California, United States*, 2. *University of California, Irvine, Irvine, California, United States*

Sleep difficulties are one of the foremost health problems that affect family caregivers of dementia patients increasing their risk for a host of mental health problems and hastening dementia patients' transitions to long-term care facilities. This integrative review aims to describe the objective measurement of sleep quality parameters of family caregivers using actigraphy and how well they are associated with self-reported subjective measures of sleep outcomes and psychological states. A search was performed using PubMed, CINAHL, and PsycInfo including articles from 2011 to 2020. Twenty studies met the inclusion criteria. Five sleep interventions (2 RCTs and 3 pre-post design) were found, including multi-component interventions (e.g., sleep hygiene, walking, day-time light therapy) that used actigraphy and other self-report measures. Duration of wearing actigraphy (wrist band/watch) varied in studies (3-days to 8-weeks). Most studies reported high accuracy and sensitivity of actigraphy. Sleep parameters measured by actigraphy included 'total sleep time', 'sleep efficiency', 'deep/light sleep', or 'wake time after sleep onset'. In eight studies, sleep parameters measured by actigraphy were significantly associated with sleep outcomes measured by sleep related self-reported scales (Epworth Sleepiness Scale, Pittsburgh Sleep Quality Index,

all $P < .05$). Eleven studies used actigraphy to examine sleep measures associated with various mental health states (depression, burden, stress, positive/negative affect) and found significant relationships (All $P < .05$). Findings support that use of actigraphy for dementia family caregivers is a valid measure of sleep parameters when compared with their sleep self-reports. Furthermore, it was found that actigraphy sleep measures were significantly associated with psychological outcomes.

UTILIZATION OF SOCIAL MEDIA PEER SUPPORT GROUPS AMONG FAMILY CAREGIVERS OF PATIENTS WITH DEMENTIA

Mary Dioise Ramos, *Kennesaw State University, Kennesaw, Georgia, United States*

Caring for a family member with dementia is particularly challenging. Unpaid family caregivers provide a significant amount of the care for aging relatives, and they provide the vast majority of long-term care. Family caregiving often results in negative effects, which compromises the caregiver's physical and psychosocial health. Social media support groups are an increasingly common venue for family caregivers supporting patients with dementia to exchange emotional, informational, and instrumental support. This study examined the utilization of social media support groups among family caregivers of patients with dementia during the pandemic. Using deductive thematic analysis, the use of social media support groups of family caregivers provide link to social interaction as a means when social distancing is enforced due to the pandemic. Family caregivers use social media support groups to share their personal experience, express their mood and feelings, offer prayers and positive quotes, keep up with the current events, gather information, and share feedback about dementia care services. Awareness of the potential advantages that social media support groups offer, healthcare providers can encourage family caregivers to use social media support groups as an empowering and practical platform. Further research is required about the long term benefit from social media support groups and the reliability and validity of the information that the family caregivers can get from the group.

Family Caregiving During the COVID-19 Pandemic

Session 9275 (Poster)

"LOCKED OUT OF CAREGIVING": A CASE STUDY OF DEMENTIA CAREGIVING DURING THE COVID-19 PANDEMIC

Kristie Wood,¹ and Marie-Anne Suizzo,² *1. University of Texas, Austin, Austin, Texas, United States, 2. UT Austin, UT Austin, Texas, United States*

It is unclear how ambiguous loss in dementia caregiving is impacted by conditions of the Covid-19 pandemic. Ambiguous loss describes situations in which closure is impossible and ambiguities within a family system ensue. Two situations of ambiguous loss exist. In the first type, one is psychologically absent, yet physically present, e.g. when one has dementia. In the second type, one is physically absent

but psychologically present, e.g. moving to a nursing home. Ambiguous loss theory was applied to longitudinal interviews with an adult-child caregiver (age=52) of a mother with dementia, who resided in memory care during the Covid-19 pandemic. Theoretical analysis revealed both types of ambiguous loss were experienced in the dementia caregiving relationship. This was embedded within ambiguous loss type 2 due to the Covid-19 pandemic, e.g. social distancing and quarantine practices led to physical estrangement from others and ambiguity ensued about when, or if, estrangement would end before resulting in death. Further, the coping mechanisms defined in the ambiguous loss framework: restructuring identity, finding meaning, gaining mastery, increasing ambivalence capacity, reframing attachments, and gaining hope, were compromised due to overarching ambiguous loss attributed to the pandemic. Continued panic and frustration regarding lack of communication with and access to the memory care center instilled a sense of being "locked out of caregiving." Findings suggest dementia caregivers may experience both types of ambiguous loss compounded during the Covid-19 pandemic, suspending grief and coping processes, and inciting poorly understood needs and challenges that must be better understood to support dementia caregivers.

A NATURAL EXPERIMENT CREATED BY PANDEMIC RESTRICTION: COMPARING IN-PERSON, HYBRID, & THERAPY FORMATS

Tracy Wharton,¹ and Daniel Paulson,² *1. University of Central Florida, Winter Springs, Florida, United States, 2. University of Central Florida, Orlando, Florida, United States*

The FL-REACH intervention for families in early stage post-dementia diagnosis was originally adapted from the REACH II program for use in an outpatient clinic. Pandemic restrictions forced an adaptation to a teletherapy format. The timing of changes allowed comparison of caregivers who participated in clinic (n=10), switched modalities mid-treatment (n=7), and participated as teletherapy (n=14). Groups were similar in age range, gender, and relationship, with both spouses and adult children participating. Participants in the fully online group were more likely than others to have high school or trade school education than to have graduated from college. All participants in the in-person and hybrid groups had incomes over \$40,000/year, while 36% of the online sample had less household income, were more likely to be Hispanic-identifying (43% versus 6%), and had higher burden scores (M=41.43 versus M=32.56 in person, M=29.86 hybrid) and lower preparedness scores (M=19.86 versus M=22.90 in person, M=28.14 hybrid) at baseline ($p < .05$). The intervention proceeded with the same intervention dosage (8 hours total), and outcomes were essentially comparable, with all groups showing statistically significant improvement on measures of preparedness, burden, and risk. While in-person intervention helped strengthen relationships with the medical team, inclusion of family via telehealth provided opportunity for a more culturally responsive and inclusive engagement, although there remain questions regarding reasons for differences at baseline. Identification of differences in key outcomes for direct comparisons between in-person, hybrid, and teletherapy interventions are limited

in the evidence base, making this a unique study at an important moment in time.

CAREGIVING DURING THE COVID-19 PANDEMIC: FACTORS ASSOCIATED WITH CAREGIVER STRESS AND COGNITION

Rachael Turner,¹ Erin Harrington,² and Celinda Reese-Melancon,² 1. *Oklahoma State University, Stillwater, Oklahoma, United States*, 2. *Oklahoma State University, Oklahoma State University, Oklahoma, United States*

Caregivers are critical in helping persons with dementia (PWD) live at home longer, but the caregiving experience is associated with increased risk of physical (Vitaliano et al., 2003; Son et al., 2007; Fonareva & Oken, 2014) and cognitive decline among caregivers (Pertle et al., 2015; Lathan et al., 2016; Vitaliano et al., 2017). The present study examined the caregiver experience during the time of the Covid-19 pandemic including factors associated with caregiver stress, burden, and self-reported cognition (i.e., prospective and retrospective memory errors). In a sample of 56 caregivers of PWD, caregiver stress was positively associated with reports of greater life change resulting from Covid-19 and a greater frequency of care recipient depressive and disruptive behaviors; however, caregiver stress was not associated with care recipient memory problems. Additionally, caregiver burden was negatively associated with ratings of preparedness for the pandemic, but not with availability of support services or the amount of time spent caregiving. Further, frequencies of prospective and retrospective memory mistakes were positively associated with perceived stress, but not with caregiver burden. These findings reveal that caregivers of PWD report greater experiences of stress associated with the Covid-19 pandemic and other facets of their caregiving responsibilities (e.g., care recipient depressive and disruptive behaviors, frequency of memory mistakes). This work is a first step in identifying areas in which caregivers need assistance and expanding the literature on caregiver cognition by measuring self-reported everyday memory performance.

CAREGIVING INTENSITY AND PSYCHOSOCIAL IMPACT OF COVID-19 IN DEMENTIA AND NON-DEMENTIA CAREGIVERS

Marika Humber,¹ Angeline Truong,² Madhuvanathi Suresh,³ Josephine Jacobs,⁴ Sam Thomas,⁵ Trevor Lee,⁶ Rashmi Risbud,⁷ and Ranak Trivedi,⁸ 1. *VA Palo Alto Healthcare System, Menlo Park, California, United States*, 2. *Stanford University School of Medicine, Stanford, California, United States*, 3. *Palo Alto University, Atlanta, Georgia, United States*, 4. *VA Palo Alto Health Care System, Menlo Park, California, United States*, 5. *Stanford School of Medicine, Stanford, California, United States*, 6. *VA Palo Alto Health Care System, VA Palo Alto Health Care System, California, United States*, 7. *VA Palo Alto Health Care System, Palo Alto, California, United States*, 8. *Stanford University, Menlo Park, California, United States*

COVID-19 has adversely impacted the well-being of informal caregivers (CG) due to infection risk, changes to the home environment, and changes to resource availability. CG of persons living with dementia (PLWD) may be especially vulnerable due to the intensity of care provided. We compared CG activities and well-being among CG who did and did not care for

PLWD during COVID-19. We conducted an anonymous online survey from April 2020-present. Respondents self-identified as 18+ years and CG to a child or adult with mental health or medical conditions. CG answered questions regarding hours of care provision and caregiving activities, and completed measures of CG burden (Zarit Burden Inventory-4), loneliness (UCLA Loneliness Scale), depressive symptoms (Patient Health Questionnaire), and anxiety (Generalized Anxiety Disorder-2). Of the 258 respondents within the United States, 86 cared for PLWD (33%; 88% female; 56±12 years) while 172 did not (66%; 87% female; 49±14 years). Compared to non-dementia CGs, more CGs of PLWD provided 40+ hours of caregiving/week (36% vs. 49%, $p < .05$), performed more caregiving activities (8.5 vs. 10.5, $p < .01$), and assisted with more activities of daily living (55% vs. 73%, $p < .01$). Compared to non-dementia CG, more dementia CG reported CG burden (53% vs. 67%; $p < .05$) and loneliness (7.3 vs. 9.1, $p < .05$). No differences in depressive symptoms or anxiety were found. Results suggest that existing needs of CG of PLWD may be exacerbated by the stressors and concerns of the pandemic, necessitating higher levels of support.

DEVELOPMENT AND INITIAL EVALUATION OF THE CARING THROUGH COVID-19 PSYCHOTHERAPY GROUP FOR FAMILY CARE PARTNERS

Evan Plys,¹ Kadija N. Williams,² Caitlin J. Tyrrell,³ and Rachel Weiskittle,⁴ 1. *University of Colorado School of Medicine, Colorado, United States*, 2. *VA Boston Healthcare System, Brockton, Massachusetts, United States*, 3. *VA Pacific Islands Healthcare System, Honolulu, Hawaii, United States*, 4. *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*

This project details the development and initial evaluation of a manualized psychotherapy support group for family care partners of persons living with dementia, specially designed to address pandemic-related stressors. The authorship team, consisting of clinical geropsychologists, developed a treatment manual based on existing protocols, such as: cognitive behavioral therapy for pandemic-related stress, grief management and ambiguous loss, and caregiver family therapy. The resulting 8-week Caring Through COVID-19 psychotherapy group was piloted in an outpatient mental health clinic via tele-mental health with six family care partners of persons living with dementia. All participants were women and spouses or partners of the care recipient; mean age was 70.5 (SD = 9.07). Preliminary data showed a non-significant and small reduction in depression ($d = .22$) and non-significant moderate reductions in caregiver burden ($d = .52$) and pandemic-related stress ($d = .64$). Moderate non-significant improvements were observed in general caregiver self-efficacy ($d = .62$) and self-efficacy for emotional regulation ($d = .67$). The majority of participants reported that the content of the group was novel (83%) and relevant (83%); the most utilized topics outside of the group were accepting emotions (100%) and challenging negative cognitions (83%). Overall, most participants were very or extremely satisfied with the group (67%). Additional data is currently being collected with another cycle of the group ($n = 4$). Preliminary findings suggest that the Caring Through COVID-19 group may be beneficial for supporting family care partners during the pandemic. Considerations for implementation and future plans for dissemination will be discussed.

LEARNING NEEDS OF DEMENTIA FAMILY CAREGIVERS DURING THE PANDEMIC

Carolyn Clevenger,¹ Fayron Epps,² Kenneth Hepburn,² Molly Perkins,³ and Glenna Brewster Glasgow,²

1. *Emory University, Emory University, Georgia, United States*, 2. *Emory University, Atlanta, Georgia, United States*, 3. *Emory University of Medicine, Atlanta, Georgia, United States*

The COVID-19 pandemic has dominated and transformed all caregiving contexts and situations. In a time of COVID-19, caregivers now have to learn how to take all of the complicated precautions to keep themselves and their persons from being exposed to the virus given their population's mortality rate from COVID-19 infections exceed 40%. As part of a larger initiative to develop an asynchronous online education program for family caregivers of persons living with dementia illnesses (PLWD) to prepare them to master the new demands of their caregiving role in this extraordinary circumstance of the COVID-19 pandemic, we conducted three focus groups with 13 dementia family caregivers to inform the structure, content, and "feel" of the course. Focus groups were conducted with a lead interviewer, via Zoom, audio and video recorded and transcribed for analysis. Participants were asked two groups of questions: their lived experience over the past year and course content for caregiving during crisis. Caregivers identified 4 themes regarding their lived experience of caregiving during the pandemic: (a) mixed feeling about the stay-at-home orders; (b) positive adaptation to telemedicine, (c) vaccine risks and benefits; and (d) impact of social isolation on the PLWD. The groups also recommended specific course content based on their experiences. Participants recommended specific course content based on their experiences, such as health system navigation and the logistics of what to do following the death of a PLWD. Results from these groups have been incorporated into an asynchronous online course to be pilot tested in coming months.

Session 9280 (Poster)

Family Caregiving II (SRPP Poster)

A SCOPING REVIEW OF YOUTH CAREGIVERS: ADDRESSING THE NEEDS OF THIS GROWING POPULATION

Heena Doshi,¹ Gracie Chen,² Norma Bostarr,³ Debra Cherry,⁴ Mary Mittelman,⁵ and Nihal Satyadev,⁶ 1. *Care Generation, Los Angeles, California, United States*, 2. *University of California, San Diego, Temple City, California, United States*, 3. *Care Generation, SF, California, United States*, 4. *Alzheimer's Los Angeles, Los Angeles, California, United States*, 5. *NYU Langone Health, NYU Grossman School of Medicine, New York, United States*, 6. *The Youth Movement Against Alzheimer's, Los Angeles, California, United States*

Generation Z, those who are born in 1997 or thereafter, account for six percent of the estimated 53 million family caregivers in the US – and this percentage is growing, especially given the health impacts of the pandemic. This review focuses on caregiving youth (ages 0-18) and young adult caregivers (ages 18-25) who assist household members who need regular assistance with ADLs and IADLs.

This presentation will analyze key trends in the literature of this demographic and identify gaps in research. Our review broadens the knowledge base of how caregiving done by this population impacts brain development, and hence their long term physical, emotional, and mental health. In spite of the significant number of caregiving youth and young adults, current publications on these demographics remain sparse, with most studies being conducted on spousal and adult caregivers. Our group found that the existing literature reviewed the adverse implications on the health and education outcomes for young adult caregivers. This included increased anxiety/depression compared to non-caregivers and for those in post-secondary education, the contribution of caregiving to college incompleteness. There are no known studies on this population who have entered the workforce and who also continue their caregiving role. Adequate understanding and characterization of caregiving youth and young adult caregivers will inform better interventions and future policy for them. Support for this demographic, in turn, may improve health outcomes for older adults, who are the majority of those in their care.

"WE'VE ALL LOST SO MUCH": THE EXPERIENCES OF ESSENTIAL FAMILY CAREGIVERS' LONG TERM CARE VISITATIONS DURING COVID-19

Charlene Chu,¹ Amanda Yee,² and Vivian Stamatopoulos,³

1. *University of Toronto, Toronto, Ontario, Canada*, 2. *University of Toronto, Calgary, Alberta, Canada*, 3. *University of Ontario Institute of Technology (UOIT), Oshawa, Ontario, Canada*

Family caregivers are integral to the care of long-term care (LTC) residents. COVID-19 public health policies initially restricted all essential caregivers from visiting LTC homes. In lieu of in-person visitations, caregivers were allowed technology-based visits then restrictive outdoor visits, followed by indoor visitations. This study aims to illuminate the experiences of essential caregivers' as they visited their loved ones in LTC during COVID-19's restrictive policies. We conducted seven caregiver focus groups (N=30) from Ontario and British Columbia, Canada. Thematic analysis and line-by-line coding were completed using NVivo. We found six themes that were common to all the visitation types: 1) "LTC Home disorganization" to facilitate visits and poor communication; 2) "Lack of staffing and resources"; 3) "Mistreatment from staff and management" as caregivers were seen as inconveniences; 4) "Shock and disbelief" when family members first saw their loved ones; 5) "Significant lack of person-centered or family-centered ethos" for example the residents' needs were ignored such that their cognitive and physical impairments sometimes made visitations impossible, as well as the burden of multiple weekly COVID-19 tests; and, 6) "Collateral damage" in the form of trauma and irreparable harm to the relationships between residents and families. These results emphasized caregivers who ultimately felt betrayed and ignored by the broader healthcare system. Our findings provide an in-depth understanding of how COVID-19 public health policies have impacted the essential caregivers and the long-lasting impacts on residents and caregivers alike. Understanding caregiver's experiences can inform future pandemic response policies and encourage more person-centered protocols.

DIFFERENCES IN SUBJECTIVE AGE BY FILIAL CARE-GIVING STATUS AMONG US ADULTS IN MID AND LATER LIFE

Hyojin Choi,¹ and Kristin Litzelman,² 1. *University of Wisconsin--Madison, Madison, Wisconsin, United States*, 2. *University of Wisconsin-Madison, Madison, Wisconsin, United States*

Subjective age is an important indicator of age identity and is associated with both psychological and physical well-being. Previous studies have revealed that older adults who feel younger than their chronological age show better health status, better life satisfaction, and less risk of mortality. Considerable evidence shows that stress contributes to feeling older than one's chronological age. Given the fact that taking a caregiving role involves stress, it is expected that caregiving might accelerate subjective aging. This study examined the association between the stressor of caregiving and subjective age in mid and later life. Data were drawn from the Health and Retirement Study in 2014 and 2016. Participants aged 50 years and over (n=1,087) were identified according to adult-child caregiver status at across the two waves: those who provided care consecutively (long-term caregivers), those who became caregivers in 2016 (new caregivers), those who were no longer providing care in 2016 (recent caregivers), or those who did not report providing care in both 2014 and 2016 (non-caregivers). Linear regression analysis showed that new caregivers reported feeling older than their chronological age compared to non-caregivers. However, long-term or recent caregivers did not show significant differences in subjective age compared to non-caregivers. The finding is consistent with the stress process theory and adaptation hypothesis. Although the onset of caregiving stress may accelerate subjective aging, this deleterious effect may decrease over time due to family caregivers' adaptability. Future research will examine the role of support, resilience and mastery in this pathway.

DIRECT-TO-CAREGIVERS RESEARCH DISSEMINATION: A NOVEL APPROACH TO TARGETING END-USERS

Lee Lindquist,¹ Anna Liggitt,¹ Vanessa Ramirez-Zohfeld,² and Shahla Baharlou,³ 1. *Northwestern University Feinberg School of Medicine, Chicago, Illinois, United States*, 2. *Northwestern University Feinberg School of Medicine, Northwestern University Feinberg School of Medicine, Illinois, United States*, 3. *Icahn School of Medicine at Mount Sinai, Icahn School of Medicine at Mount Sinai, New York, United States*

Dissemination of geriatrics research usually occurs through conference presentations or publications viewed by colleagues in the same field. Older adults and their family caregivers have limited direct access to research findings. We sought to pilot a direct-to-caregiver workshop with the intent to disseminate geriatrics research directly to family caregivers of older adults. As part of an academic national conference, an 'Updates in Geriatrics Research' workshop is presented as a compilation of innovative research published in the prior year. We distilled workshop content into a lay format which was presented to family caregivers at two community-based caregiver symposiums. Mixed method

surveys were completed by family caregiver attendees with open-ended responses analyzed using content and constant-comparative techniques. Of the 29 survey respondents, all were female, mean age 58.9 yrs. (range 52-72), providing care to older adults, mean age 87.2 years (range 66-97). Respondents unanimously identified learning information pertinent to their care recipient. When asked: Do you feel that direct-to-caregiver research dissemination is useful, all respondents selected yes. Open-ended responses for reasons why revealed two main themes: 1.) Creating informed caregivers: "Caregivers need this information in their toolbox." and 2.) Empowering caregiver-advocates: "The more we know, the better we can advocate for our loved ones and challenge their health care." Respondents all planned on sharing information with others, specifically family, friends, and physicians. In conclusion, disseminating geriatrics research direct-to-caregivers is feasible. Researchers, who present their work for scientific conferences, should consider translating their findings into presentations for community-based family caregivers.

DYNAMICS OF UNMET NEED FOR SOCIAL CARE IN ENGLAND

Athina Vlachantoni, Jane Falkingham, Maria Evandrou, and Min Qin, *University of Southampton, Southampton, England, United Kingdom*

Meeting individuals' social care needs is a core element of UK social policy. However, the conceptualisation and operationalisation of 'unmet need' remain a challenge. This paper advances our understanding by incorporating a temporal dimension in the conceptual framework on unmet need to investigate the dynamics of met and unmet need for social care over time. Using data from Waves 6,7 and 8 of the English Longitudinal Study of Ageing, this paper examines five possible trajectories among individuals with a social care need at baseline: 1) no longer having such a need; 2) having continued needs met; 3) delayed needs met; 4) newly arisen unmet needs; and 5) persistent unmet needs. The results indicate that amongst those with need at baseline unmet need has decreased over time, indicating that some needs may be fulfilled with a delay. However, a significant proportion of older people experienced persistent unmet needs, particularly those who were younger, living alone, with educational qualifications, and with fewer difficulties with Activities of Daily Living at baseline. Understanding the dynamics of unmet need can support policymakers in ensuring that those facing an elevated risk of persistent unmet need over time do not fall through the social care safety net.

EXAMINING PHYSICAL AND SOCIAL ENVIRONMENTS OF KOREAN AMERICAN FAMILY CAREGIVERS OF PERSONS LIVING WITH DEMENTIA

Kathy Lee,¹ Jon Shuffler,² Hye-Won Shin,³ Joshua Grill,³ Chang Hyun Seo,² and Christina Miyawaki,⁴ 1. *University of Texas at Arlington, Coppel, Texas, United States*, 2. *University of Texas at Arlington, University of Texas at Arlington, Texas, United States*, 3. *UC Irvine Institute for Memory Impairments and Neurological Disorders (UCI MIND), UC Irvine Institute for Memory Impairments and Neurological Disorders (UCI MIND), California, United*

States, 4. University of Houston, University of Houston, Texas, United States

Introduction: East Asian Americans are considered a hard-to-reach population in the field. Existing resources are not inclusive of Korean family caregivers, and therefore, a community support system may be required for this ethnic group. **Methods:** We conducted a telephone-based survey and in-depth interview with Korean family caregivers of persons with dementia (N=36; Mean age: 63.3) to examine their physical and social environments. **Results:** Most caregivers (58%) co-resided with their care recipients. Those providing care with limited assistance from others showed greater financial hardship ($p=0.03$) and interference with employment ($p=0.03$). Job interference was further related to higher levels of caregiving burdens ($p=0.01$). The services used most were senior center services (25%) and in-home care services (17%), while desired services included health promotion and disease prevention services (50%) and culturally appropriate or medically tailored home-delivered meals services (31%). Caregivers socialized with others using a multi-messaging app (i.e., KakaoTalk) with others. About 74% of them addressed they used KakaoTalk always (52%) or often (22%), and nearly half of them (47%) said they searched for caregiving information online. Findings from our qualitative interviews confirmed positive attitude toward the use of technology. Korean family caregivers showed a lack of knowledge of not only existing community-based resources but also the disease-related information, particularly regarding early-stage support and home safety. **Conclusion:** It is critical to develop a community education program that reflects their unique physical and social environment conditions, potentially through technologically delivered interventions, for outreach and engagement for Korean family caregivers of persons with dementia.

FAMILY CAREGIVING AND DEPRESSION AMONG OLDER ADULTS IN JAPAN: A CROSS-SECTIONAL STUDY DURING THE COVID-19 PANDEMIC

Taiji Noguchi,¹ Takahiro Hayashi,² Yuta Kubo,² Naoki Tomiyama,² Akira Ochi,² and Hiroyuki Hayashi,²
1. National Center for Geriatrics and Gerontology, Obu, Aichi, Japan, 2. Seijoh University, Tokai, Aichi, Japan

COVID-19 infections are particularly lethal in older adults; thus, social activities of older adults and their families in the community have been restricted. The threat of infection, restrictions on social activities, and limitations on the provision of care services for older adults could increase family caregivers' burden and impact their mental health. This cross-sectional study examined the association between family caregiving and change in depression during the COVID-19 pandemic. In October 2020, we conducted a mailed questionnaire survey on a random sample of functionally independent community-dwelling older adults in a semi-urban area of Japan. Based on the depression status between March and October 2020, participants were classified into four groups: "consistently non-depressed," "depression onset," "recovering from depression," and "remained depressed." Participants were assessed for providing care for their family members or not. Caregiver participants were also assessed on their caregiving role (primary or secondary), the severity of their care-recipient's needs, and an increased

caregiver burden. Data from 957 older adults were analyzed. The participants' mean age (SD) was 80.8 (4.8) years, and 53.5% were female. Multivariable multinomial logistic regression analysis revealed that family caregiving was associated with depression onset (OR=3.17 [95%CI=1.57-6.40], $p=0.001$) and remaining depressed (2.53 [1.36-4.71], $p=0.004$). Particularly, primary caregivers, those providing care for family members with severer care need-levels, and those with an increased caregiver burden had a higher risk of depression onset and remaining depressed. Family caregivers could have severe mental health conditions during the pandemic. Developing a support system is essential to protect their mental health.

HOPE, ACTIVE COPING AND WELL-BEING IN STROKE-SURVIVORS AND CAREGIVERS: AN ACTOR-PARTNER MODEL ANALYSIS

Esther Chow,¹ and Sai-fu FUNG,² 1. City University of Hong Kong, Kowloon, Hong Kong, 2. City University of Hong Kong, Kowloon, Hong Kong

Purpose: Stroke is a medical condition cause of suffering for both patients and their caregivers within the family. This paper aimed to assess the influence of the psychological construct of hope and active coping on hedonic wellbeing in patient with stroke and caregiver dyads by determining the dyadic patterns. **Methods:** A baseline study including 200 stroke-survivor (Age 73.63; SD=7.22) and caregiver (62.49; SD=14.44) dyads with actor-partner interdependence model (APIM) estimated by structural equation modelling with maximum likelihood estimation. Herth Hope Index (HHI), Proactive Coping Inventory (PCI) and Personal Wellbeing Index (PWI) were used to measure hope, proactive coping and wellbeing, respectively. **Results:** The APIM analysis revealed that both stroke patients and caregivers demonstrated double actor-only pattern. As such, stroke-survivors' hope and active coping exerted an actor effect on their own wellbeing with $\beta = 0.48$ ($p < 0.01$) and 0.16 ($p < 0.01$), respectively. Similarly, the caregiver also reported an actor effect between hope and wellbeing ($\beta = 0.84$, $p < 0.01$) as well as active coping with wellbeing ($\beta = 0.37$, $p < 0.01$). The overall SEM model also fulfilled the criteria for good model fit (χ^2 (5.87), $p = > 0.05$, CFI = 0.98, TLI = 0.96 and RMSEA = 0.07). **Conclusions:** The results suggest that both stroke patients and caregivers' hedonic wellbeing are holding actor-oriented pattern with the hope and active coping. The implications for clinical practitioners, research and theoretical development are discussed.

INNOVATIONS ON DEMENTIA ADVOCACY AMONG STUDENTS OF A MEDICAL UNIVERSITY IN TAIWAN

Tsuann Kuo, Chung Shan Medical University, Chung Shan Medical University / Taichung City, Taichung, Taiwan (Republic of China)

In 2017, Taiwan established Dementia Action Plans 2.0 to respond to the World Health Organization's call to increase dementia awareness and support for dementia carers. However, efforts have not yet been made to educate and increase dementia literacy on the younger generations. This paper addressed the outcomes to increase knowledge and information about dementia and caregiver resources to university students. 93 students participated in a two-day

workshop on dementia literacy, followed by two months of advocacy in Taichung City, Taiwan. Students were divided into 14 advocacy groups and the outcome reports were categorized qualitatively using content analysis. The results showed that students were from nine departments and over one-quarter having a dementia loved one in the family. Four innovative categories were developed, including (1) dementia literacy for students and the public; (2) dementia friendly action plans; (3) dementia caregiver's advocacy and (4) reducing dementia stereotypes. Highlights included students using social media to promote dementia literacy, face-to-face experiences to inform public education, dementia education on early onset dementia and using diverse bio-psycho-social angels to evaluate dementia. Students expanded advocacy to many social media, innovations and target areas, including Facebook, Instagram, Google spreadsheet, stickers, post-cards, illustration of children's books and public announcement. This paper revealed that younger generations used many advocacy methods that were thinking outside of the box. In conclusion, dementia is no longer an elder's business but young adults can bring technological, inter-generational and cultural innovations into fulfilling the goals of Dementia Global Action Plans.

KEY FACTORS IN INTERVENTION IMPLEMENTATION, FIDELITY, AND SUSTAINABILITY

Carey Sherman,¹ Kate Gordon,² and Kenneth Hepburn,³ 1. *Family Care Strategies, LLC, Ann Arbor, Michigan, United States*, 2. *Spilane Consulting, Columbia, Maryland, United States*, 3. *Emory University, Atlanta, Georgia, United States*

As part of an NIA-supported effort to develop an online course to train individuals to lead the evidence-based Savvy Caregiver program and to orient sponsoring organizations to the program, we conducted semi-structured interviews to assess success and sustainability "best practices". Interviews were conducted with 17 leaders and trainers from eleven Savvy-providing organizations. Analysis of these interviews identified two main themes associated with successful program implementation: leadership commitment and trainer ownership. Paramount to success appears to be leaders' clear understanding of and enthusiastic commitment to the value of the Savvy program to the organization's constituents. This translated to careful selection, training, management and on-going development of Savvy program trainers. It contributed to leaders' appreciation of Savvy as a gateway for clients to seek out other programs and services from the organization, while the gathering of meaningful evaluation data (using established outcome-assessment instruments) contributed, in several cases, to garnering more lasting support to deliver the program. Organizations' commitment to the program was demonstrated by securing the kinds of adequate and appropriate training, typically involving both instruction and modeling, for Savvy program leaders. These efforts fostered a sense of ownership among the leaders – the sense that the program had positive value for the caregivers served. These findings should be of interest both to scholars engaged in the development of interventions and for organizations implementing them. Taken together, the themes highlight several factors for program implementation that maximize the chances of maintaining fidelity to core program principles and ensuring its sustainability.

PIVOTING DURING THE PANDEMIC: A CASE STUDY OF THE SENIOR COMPANION PROGRAM PLUS

Noelle Fields,¹ Ling Xu,¹ Erin Roark,² Sruthi Sundar,² Ishan Williams,³ and Joseph Gaugler,⁴ 1. *University of Texas at Arlington, Arlington, Texas, United States*, 2. *The University of Texas-Arlington, Arlington, Texas, United States*, 3. *University of Virginia, Charlottesville, Virginia, United States*, 4. *University of Minnesota, Minneapolis, Minnesota, United States*

Introduction: Growing research supports the use of older volunteers to provide respite and community-based assistance to persons with ADRD and their caregivers. This study explores the impact of COVID-19 on a face-to-face, peer-led psychoeducational intervention for African American ADRD family caregivers, the Senior Companion Program Plus (SCP-Plus), and its subsequent need to 'pivot' during the pandemic. Method: The SCP-Plus was a randomized control trial across three states that assessed program impact on ADRD family caregiver stress/burden, coping, and social support. In spring 2020, the SCP-Plus intervention was halted because of the potential risk to participants due to COVID-19 (n = 20 enrolled dyads). In an effort to maintain rapport and trust, critical to retention in research studies, team members began weekly (March-April) and then bi-weekly calls (May-December) for the purpose of providing a social check-in and to provide updates on the status of the intervention. Results: A total of 396 calls lasting approximately 10 minutes each were completed. Participants shared concerns around safety, access to food/supplies/masks/testing, feelings of stress and loss, concern for others, and the importance of technology as a means of social connection. Although the intervention aspect of the SCP-Plus ultimately ended due to COVID-19, information gleaned from these check-ins were used to pivot the study. The study moved forward by using a descriptive phenomenological approach to capture dyads' lived experiences during COVID-19. Discussion: Overall, purposeful participant engagement through weekly/bi-weekly phone calls suggests that this is a promising strategy for participant retention as well as for pivoting research.

PPA TELE-SAVVY: DEVELOPING AN ONLINE INTERVENTION WITH CAREGIVERS OF PERSONS WITH PRIMARY PROGRESSIVE APHASIA

Darby Morhardt,¹ Angela Roberts,² Alyssa Penn,² Allison Lindauer,³ Emily Rogalski,¹ Sandra Weintraub,¹ and Kenneth Hepburn,⁴ 1. *Northwestern University, Chicago, Illinois, United States*, 2. *Northwestern University, Evanston, Illinois, United States*, 3. *Oregon Health Sciences University, Portland, Oregon, United States*, 4. *Emory University, Atlanta, Georgia, United States*

Primary progressive aphasia (PPA) typically results from a neurodegenerative disease such as frontotemporal lobar degeneration or Alzheimer's disease and is characterized by a progressive loss of specific language functions with relative sparing of other cognitive domains until later stages when widespread cognitive decline consistent with generalized dementia is more prevalent. PPA tends to appear earlier than most dementias, in late middle-age, and can result in a high degree of psychological and economic burden for the family. Thematic analysis of PPA caregiver studies reveal families are learning to adapt to not only declining language across

communicative contexts and domains, but concomitant behavioral, social communication and personality changes over time. While there are several evidence-based dementia caregiver interventions, none are specifically designed for the PPA family caregiver. This pilot project, funded by the Emory University Roybal Center is the adaptation of an evidence-based on-line psychoeducation program (Tele-Savvy) to address the unique challenges facing informal caregivers of those living with PPA and to help these caregivers achieve mastery within this context. PPA caregivers have been engaged through focus groups to identify their most pressing caregiving challenges and how the existing Tele-Savvy curriculum should be adapted to meet their needs. Synchronous and asynchronous video modules have been designed to address: PPA education, the impact on dyadic connection and caregiving challenges and communication strategies specific to PPA. The Tele-Savvy central processes of coaching and de-briefing will also be pilot tested and refined.

Session 9285 (Poster)

Family Caregiving: Interventions and Support

FAMILY CAREGIVERS AND SUPPORT: IMPLICATIONS FOR WORK STRAIN AND FORMAL SERVICE USE

Joseph Svec, and Jeongeun Lee, *Iowa State University, Ames, Iowa, United States*

In the US, many employed caregivers make professional adjustments, exacerbating already tenuous balances between work and life. Using the framework of the Stress Process Model (SPM), current research examines the sources of support (both formal and informal) and the contextual factors that facilitate or impede caregiver support. In this research, we examine whether and to what extent caregiver work strain is ameliorated by the presence of additional family caregivers and formal service use. This study utilizes data provided by the National Study of Caregiving (NSOC) data. Using panel methods for the pooled waves, we analyze the associations between work-strain and the number of additional caregivers with utilization of formal support (such as paid service support). Preliminary analyses align with the Stress Process Model as additional caregivers for each respective care-recipient is associated with lower levels of work strain. On the other hand, utilization of formal services (paid help and Medicaid funding) is positively associated with work strain. These findings suggest that the number of additional caregivers can reduce the negative impact of caregiving on work related strain among employed caregivers. That is, multiple caregivers may be more reflective of cooperative arrangements which offset work disruptions that occur with the onset of caregiving. In addition, formal sources may more frequently be used as a last resort to address caregiver burnout. Ongoing analyses are examining changes in the number of caregivers and its impact on disruptive work event, which could lead to financial outcomes for caregivers.

INTERDISCIPLINARY COMMUNITY-BASED SUPPORT FOR CAREGIVERS OF INDIVIDUALS LIVING WITH DEMENTIA

Gina Tucker-Roghi,¹ Jamie Escoubas,² Renee Tolliver,² and Sarah Tucker,² *1. Dominican University of California, SAN*

RAFAEL, California, United States, 2. Sonoma County Council on Aging, Santa Rosa, California, United States

Evidence indicates family caregivers of individuals living with dementia (ILwD) are at risk for diminished physical and mental health; which may decrease their quality of life and directly impact their ability to provide care. An interdisciplinary approach to self-care and skill-building for caregivers is provided in a virtual support group offered by Council on Aging in Sonoma County, CA. As part of the nonprofit's Adult Day Program, the group is offered to client caregivers and has two goals: First, creating a community-based, long-term support system for ILwD who are aging-in-place; second, fostering a safe and supportive community for family caregivers, by providing opportunities to collaborate with peers and an interdisciplinary team that includes a Marriage and Family Therapist (MFT), an Occupational Therapist (OT), and a Recreation Therapist (the day program manager). The closed group model established through eight weekly sessions builds trusting relationships in a frame that combines: the OT client-centered and collaborative approach to problem-solving everyday challenges of caregiving, the MFT skills of creating a safe space for discussion and deeper exploration, and program staff insights regarding the ILwD's current interests and abilities exhibited during Day Program activities. Sessions include an emotional check-in by group members; a brief overview of best-practices and common caregiving concerns related to a weekly topic; and an opportunity for caregivers to explore the integration of best-practices into daily routines, while also attending to their well-being as caregivers. Program evaluation and results related to the program's effectiveness and implications for scalability will be discussed.

PSYCHOSOCIAL INTERVENTIONS FOR PEOPLE WITH DEMENTIA AND THEIR CAREGIVERS IN PRIMARY CARE

Lou Frankenstein, and Georg Jahn, *Chemnitz Technical University, Chemnitz, Sachsen, Germany*

Psychosocial interventions, such as occupational and behavioral therapy are effective opportunities to support people with dementia and their caregivers in adapting to the cognitive and behavioral changes and the resulting challenges in everyday life they are facing. However, psychosocial interventions do not seem to have found their way into routine care yet. We wanted to get an insight into the knowledge and attitudes general practitioners have about occupational and behavioral therapy. In an online survey we asked medical students about the relevance of dementia, occupational therapy, and behavioral therapy during their studies. In another online survey we asked practitioners what they had learned about these topics and to what extent they are making use of psychosocial interventions. Then semi-structured interviews were carried out with general practitioners all over Germany, exploring their experiences with dementia and psychosocial interventions in primary care as well as their expectations regarding interdisciplinary cooperation. It became obvious that psychosocial interventions are not conveyed sufficiently within medical school. A lack of occupational therapy prescriptions for people with dementia seemed to result from uncertainties regarding the content of the approach and the budgeting of the prescriptions. Barriers for prescriptions of

behavioral treatment were a lack of therapy places and the perceived inadequacy of the approach for this target group. General retentions to invest in people with dementia were expressed. These obstacles need to be overcome in order to provide optimal care for people with dementia and their family caregivers.

QUALITATIVE STUDY OF AN MHEALTH MINDFULNESS INTERVENTION WITH CAREGIVERS OF OLDER ADULTS WITH MCI OR DEMENTIA

Danielle Llanaez,¹ XinQi Dong,² Paul Duberstein,³ and Elissa Kozlov,⁴ 1. Rutgers University, New Brunswick, New Jersey, United States, 2. Rutgers University, Rutgers Institute for Health, New Jersey, United States, 3. Rutgers University School of Public Health, Piscataway, New Jersey, United States, 4. Rutgers University, Rutgers University, New Jersey, United States

Caregivers of patients with dementia experience high levels of emotional distress. mHealth interventions have the potential to feasibly address some needs of caregivers and reduce stress. This qualitative research study of (n = 15) caregivers of patients with dementia explored caregivers' experience using a mindfulness meditation mobile application. The qualitative interviews were guided and structured to allow participants to share their perceived benefits, drawbacks, likes, and dislikes of using mHealth strategies to manage stress and anxiety. We asked about the caregivers' experience with mindfulness before the study, use of the app, their positive/helpful and negative/unhelpful app experiences, the perceived value of the app, and potential enhancements of the app. Caregivers reported that the app was easy to use, engaging and that there were many perceived benefits. They also noted multiple barriers to using the app including time constraints and implementation of mindfulness techniques outside of direct app use. Most of the caregivers recommended using the app to increase knowledge of mindfulness and to reduce stress. Our findings support the growing body of literature on the practical use of mHealth strategies for caregivers. Future work should address the perceived barriers caregivers encounter when using mHealth strategies.

SELF-EFFICACY IN THOUGHT CONTROL, NOT POSITIVE GAINS, MEDIATES EFFECT OF BENEFIT-FINDING INTERVENTION FOR CARERS

Sheung-Tak Cheng, Education University of Hong Kong, The Education University of Hong Kong, Not Applicable, Hong Kong

This study examines the therapeutic mechanism of the benefit-finding therapeutic (BFT) intervention that used cognitive reappraisal and alternative thinking to construct positive aspects of caregiving (PAC), in a cluster-randomized controlled trial for Alzheimer caregivers. 42 caregivers received BFT whereas 87 received psychoeducation as control. Both interventions were held in groups. Depressive symptoms and global burden were outcomes measured at baseline, postintervention, and 4- and 10-month follow-up. Mediators considered included PAC and three self-efficacies—controlling upsetting thoughts (SE-CUT), responding to disruptive behaviors, and obtaining respite. Using mixed-effects regression, we demonstrated that benefit-finding increased caregivers' PAC and SE-CUT, but that only SE-CUT uniquely

predicted depressive symptoms and global burden longitudinally. Path analyses with bootstrapped confidence intervals showed that SE-CUT change from baseline to postintervention mediated intervention effects on depressive symptoms, but not global burden, at both follow-ups. No mediation effects were found for PAC and the other self-efficacies. As a conclusion, The BFT effect on depressive symptoms was partly accounted for by improvement in SE-CUT. The therapeutic mechanism for the effect on burden remained unknown. The study sheds light on the importance of actively promoting positive caregiver functioning.

SUPPORTING OLDER FAMILY CAREGIVERS OF YOUNG ADULTS WITH IDD: A PILOT PROGRAM WITH SOCIALLY ASSISTIVE ROBOTICS

Ling Xu,¹ Julienne Greer,² Noelle Fields,¹ Priscila Tamplain,² John Bricout,³ Bonita Sharma,⁴ and Kristen Doelling,⁵ 1. University of Texas at Arlington, Arlington, Texas, United States, 2. The University of Texas at Arlington, Arlington, Texas, United States, 3. University of Minnesota, twin cities, Minnesota, United States, 4. UT-San Antonio, San Antonio, Texas, United States, 5. UTA, Arlington, Texas, United States

Introduction: The need for caregiver respite is well-documented for the care of persons with IDD. Social Assistive Robotics (SAR) offer promise in addressing the need for caregiver respite through 'complementary caregiving' activities that promote engagement and learning opportunities for a care recipient (CR) with IDD. This study explored the acceptability and usefulness of a SAR caregiver respite program responsive to feedback from both the CRs and their older family caregivers (age 55+). Methods: Caregiver-CR dyads (N = 11) were recruited. A mixed methods research design was deployed in three phases: Phase I with four focus groups to inform the program design; Phase II for program demonstration and evaluation with pre- and post-surveys; and Phase III with post-program interviews for feedback and suggestions. Results: Quantitative data analysis in Phase II showed both caregivers and their CRs scored favorably the social presence of the robot (Pepper) and social engagement with Pepper. Caregivers also reported positive perceptions of Pepper in terms of anthropomorphism, animation, likeability, intelligence, and safety. Content analysis from Phase III interviews suggested that the SAR may offer physical/emotional respite to caregivers by providing companionship/friendship as well as promoting independence, safety/monitoring, and interactive engagement with children. Discussion: SAR has potential in providing respite for older family caregiver demonstrated by the levels of CR engagement and learning with Pepper. Future studies need a longer program design and larger sample size to test the feasibility and efficacy of the intervention.

THE IMPACT OF SOCIAL SUPPORT ON DEMENTIA CAREGIVERS' PSYCHOLOGICAL WELL-BEING: IS ONLINE COMPARABLE TO OFFLINE?

Eun-Hye Yi, Indiana State University, United States

Along with the groundbreaking development of communication technology, caregivers have migrated to online platforms to seek help. Social support theory, including main effect and moderation effect models, has provided a

framework to understand the association among caregivers' stress, support from others, and their well-being. Despite the prevalence of online use for seeking help among caregivers, studies on the use of online social support within the context of caregivers' stressors and well-being are still underdeveloped. Guided by social support theory, this study aimed to examine the association of online social support (OnSS) and caregivers' mental health (MH) as compared with offline social support (OffSS). A subsample of caregivers of persons with Alzheimer's from the Health Information National Trends Survey from 2017-2018 was selected ($n=264$). For an analysis, ordered logistic regression models with Jackknife estimation methods were applied using Stata 15.1SE. First, OffSS had a positive direct association with caregivers' MH (Odds Ratio=12.48, $p<.05$) while OnSS did not. Next, the moderation effect model analysis found that OffSS interacted with caregiving burden while OnSS interacted with life stressors. The MH of caregivers who are in less favorable situations, such as working part-time while caring for a person with Alzheimer's, living with economic hardship, and having health problems, tended to be significantly affected by OnSS. Identifying the different roles of OnSS and OffSS for caregivers' MH, the findings of this study call for more attention to developing novel strategies and sensitive approaches to support family caregivers, especially those who fall in underserved groups.

THE RELATIONSHIP BETWEEN BURDEN AND FINANCIAL FACTORS FOR HELP-SEEKING OLDER ADULT CAREGIVERS

Sara Qualls,¹ Stacy Yun,² Kendall Weber,³ and Geffen Ferszt,² 1. *University of Colorado Colorado Springs, University of Colorado at Colorado Springs, Colorado, United States*, 2. *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*, 3. *University of Colorado at Colorado Springs, University of Colorado at Colorado Springs, Colorado, United States*

Older adult caregivers often experience unique financial challenges (Schultz & Eden, 2016). The purpose of the present study was to explore the relationship between caregiver finances and caregiver burden for this sample. A sample of 131 caregivers seeking counseling services completed questionnaires assessing demographics, care recipient functioning (ADLs/IADLs), and finances (yearly income, impact of caregiving on finances). A majority, 74.8% of caregivers, indicated financial burden since caregiving. A hierarchical multiple regression was computed to predict caregiver burden. The caregiving characteristics block explained 8.1% of the total variance in caregiver burden, $F(7, 123) = 1.54$, n.s. Specifically, being younger was significantly associated with more caregiver burden. Adding the care recipient functioning block explained an additional 6.9% of the variance in caregiver burden, $Fchange(2, 121) = 4.93$, $p < .01$. The caregiving characteristics and care recipient functioning model accounted for 15% of the total variance in caregiver burden, $F(9, 121) = 1.55$, $p < .05$. Again, younger age uniquely predicted greater caregiver burden. Lastly, caregiving finance factors contributed an additional 13.5% of the variance, $Fchange(4, 117) = 5.54$, $p < .001$. Thus, the final caregiver characteristics, care recipient functioning, and caregiving finances model accounted for 28.5% of the total variance in

caregiving burden, $F(13, 117) = 3.59$, $p < .001$. Specifically, having less income and greater monthly expenses related to caregiving predicted higher levels of caregiver burden. These findings imply that those with fewer resources may benefit from intervention for the heavier burden they perceive compared to peers with more financial resources.

Session 9290 (Poster)

Family Caregiving: Mental and Physical Health

A SCOPING REVIEW OF THE EXAMINATION OF SANDWICHED CAREGIVERS' PSYCHOLOGICAL WELL-BEING AND PHYSICAL HEALTH

Barbara Hodgdon, Jen D. Wong, and Patricia S. Pittman, *The Ohio State University, Columbus, Ohio, United States*

As numbers of sandwiched caregivers in the United States grow, it is essential to document the literature on the impact of dual care responsibilities on aspects of psychological well-being and physical health. This scoping review examined the literature on sandwiched caregivers' psychological well-being and physical health, identified gaps in the literature, and provided suggestions for future studies to advance the literature on sandwiched caregivers in the United States. Guided by the Arksey and O'Malley (2005) framework, this scoping review comprised of 15 peer-reviewed articles between 1980 and 2019, that examined aspects of the psychological well-being (e.g., depression, affect) and physical health (e.g., health behaviors, chronic conditions) of sandwiched caregivers in the United States. Findings showed that there was ambiguity surrounding the conceptualization of sandwiched caregivers, specifically how older and younger care recipients were defined. Also, most studies examined psychological well-being while physical health was understudied. The findings of this review also showed that, compared to non-sandwiched caregivers (e.g., spousal, filial caregivers) and non-caregivers, sandwiched caregivers exhibited greater depressive symptoms and psychological distress as well as poorer health behaviors. Furthermore, sandwiched caregivers who were female and employed were more susceptible to greater depressive symptoms than their employed male counterparts or employed non-caregivers. In considering future directions, more work is needed that examines physical health. Additionally, sandwiched caregivers of minority status merit attention as multigenerational care occurs at greater rates in these populations. Finally, caregiving during the pandemic may have a detrimental impact on sandwiched caregivers' lives which should be investigated.

ACT-RELATED PROCESSES: VALUE-BASED LIVING ATTENUATES MEDITATING RELATIONSHIPS IN CAREGIVER STRESS OUTCOMES

Elizabeth Braungart Fauth,¹ Joshua Novak,² Ty Aller,¹ Heather Kelley,¹ and Michael Levin,¹ 1. *Utah State University, Logan, Utah, United States*, 2. *Auburn University, Auburn, Alabama, United States*

Associations between behavioral and psychological symptoms of dementia (BPSD), caregiver burden, and depressive symptoms are well-established, and these constructs are often targeted in interventions. Increasingly, dementia caregiver

interventions are informed by mindfulness- and acceptance-based approaches, such as Acceptance and Commitment Therapy (ACT). In addition to standard outcomes, like burden and depressive symptoms, these interventions/therapies seek improvements in individuals' psychological flexibility (e.g., cognitive defusion, present moment awareness, values-based living). Less is known how these constructs interact within well-established caregiver stress processes. We examined a moderated mediation model (N=161 dementia caregivers; PROCESS Procedure; SPSS Release 2.16.1), with BPSD frequency (Revised Memory and Behavior Problems Checklist) predicting depressive symptoms (10-item CES-D), mediated via caregiver burden (short Burden inventory). The moderator was the Values Questionnaire (Progress scale), and we controlled for gender, caregiver duration, age, income, and education. Results revealed that the indirect effect of BPSD on depressive symptoms through caregiver burden was weakened through higher progress toward values (moderated mediation significant at $p < .05$). In essence, greater levels of living according to values dampened the effect of BPSD on depressive symptoms, through care-related burden. These findings are important because caregivers often cannot leave this role, requiring them to learn to live with the caregiving role in healthy ways. Value-based living and committed action toward values signify caregivers' success at balancing care-related stress with other priorities, and psychologically adjusting to difficulties. Interventions that emphasize values-based living, like ACT, have promise for caregivers, offering healthy ways to psychologically adjust to, and live with, the experience.

ANTICIPATORY CAREGIVING SCALE: DEVELOPMENT AND PRELIMINARY VALIDATION

Kendall Weber,¹ and Sara Qualls,² 1. *University of Colorado at Colorado Springs, University of Colorado at Colorado Springs, Colorado, United States*, 2. *University of Colorado Colorado Springs, University of Colorado at Colorado Springs, Colorado, United States*

Background: As public awareness of family caregiving has grown, adults likely anticipate the role they may play as a caregiver for an aging loved one. Although anticipatory planning for caregiving has been studied, no measure of multiple dimensions of the anticipated caregiving experience exists. The purpose of the present study is to develop and validate the Anticipatory Caregiving Scale (ACS), an assessment of adult children's attitudes toward and level of expectation surrounding their potential role as an informal caregiver to a parent or parent-in-law. **Method:** The ACS consists of six subscales that assess multiple factors that may influence willingness to or expectations about taking on a caregiving role: affect surrounding future caregiving, anticipated lifestyle interference, self-efficacy surrounding future caregiving, anticipated caregiving resources, endorsement of norms of family care which influence anticipated caregiving, and the relationship quality, current and anticipated, with the potential care recipient. A sample of 540 adults aged 18 and over recruited online completed the ACS, along with scales to assess convergent, discriminant, and concurrent validity. **Results:** Overall, the ACS and its subscales demonstrated good reliability and validity, established through internal consistency, and convergent, discriminant, and concurrent

validity. **Discussion:** The ACS fills a gap in the current literature by providing a comprehensive, multidimensional assessment examining expectations about one's potential caregiving experience, specific to the adult child-parent dyad. Future studies should examine the psychometric properties of the ACS in a more diverse population of adults across different settings and assess the temporal stability and criterion validity of the scale.

CAREGIVERS' MEDICAL CARE PROVISION AT PATIENT END-OF-LIFE: ASSOCIATIONS WITH EMOTIONAL DIFFICULTY AND GAINS

Amanda Leggett,¹ Hyun Jung Koo,² Elaina Baker,² and Hannah Lee,² 1. *The University of Michigan, Ypsilanti, Michigan, United States*, 2. *University of Michigan, Ann Arbor, Michigan, United States*

Family caregivers play crucial roles in patient care and medical decision making, especially at end-of-life (EOL). Yet, most research focuses on caregivers' burden, with little attention to rewards that make for a fulfilling EOL care experience. We consider caregiver involvement at EOL and associations with caregiver stress and gains. Data are drawn from the 2017 National Study of Caregiving's last month of life and core interviews which includes caregivers (n=283) for a nationally representative sample of Medicare eligible older adults, and questions caregivers about their care provision and EOL experience. We consider indicators of caregivers' involvement in medical decision making and support received from providers as predictors of caregivers' emotional difficulty and gains at EOL utilizing linear regressions controlling for demographic characteristics. Caregivers were 60.7 years of age on average, 72.5% female, 21.3% non-white, and 11% were spousal partners. Making medical decisions was associated with increased emotional difficulty at EOL (B=0.93, SE=0.24, $p < .001$). In contrast, more caregiving gains were associated with having care decisions align with the CG's wishes (B=-0.64, SE=0.30, $p < .05$), being more informed by providers (B=0.41, SE=0.16, $p < .05$), helping the care recipient with anxiety or sadness (B=0.69, SE=0.28, $p < .05$), and surprisingly, feeling that care decisions were made without their input (B=0.82, SE=0.29, $p < .01$). Being more involved and informed in care was associated with both positive and negative caregiver outcomes at EOL. Understanding caregiver emotional difficulty and gains at EOL are critical for identifying how clinicians can better support caregivers at EOL and improving the caregiving experience.

CAREGIVING IN OLDER ADULTHOOD AND MEANING IN LIFE

Zainab Suntai, *University of Alabama, Tuscaloosa, Alabama, United States*

While most of the literature on caregiving in adulthood focuses on grandparenting, there is an increasing trend of older adults providing care to an adult care recipient. Older caregivers are often females who are providing care to a spouse with medical conditions and are often doing so while coping with their own functional limitations, with limited support. Within the older adult literature, studies have captured the strain experienced by caregivers of older adults, who are often burdened by the loss of time and opportunity as a result of caregiving. For caregivers in older adulthood however,

caregiving may be an avenue to remain engaged and active, and a way to have purpose in life. Therefore, the purpose of this study was to examine the association between caregiving in older adulthood and meaning in life. Data from the 2018 National Health and Aging Trends study were used, which is an annual longitudinal panel survey of Medicare beneficiaries in the United States. Chi square tests were used for bivariate analyses and a logistic regression model was used to predict meaning in life based on caregiving status. After accounting for all other explanatory variables, caregivers were 50% more likely to have meaning in life compared to non-caregivers (OR=1.501, CI= 1.493-1.510). This indicates that caregiving can be a form of meaningful/productive engagement for older adults and interventions should focus on providing adequate emotional and financial support to older caregivers.

CAREGIVING SELF-EFFICACY AS A MEDIATOR OF NEGATIVE EMOTIONAL STATES AND POTENTIALLY HARMFUL BEHAVIORS

David Hancock,¹ Sara Czaja,² and Richard Schulz,³ 1. *Weill Cornell Medicine, New York City, New York, United States*, 2. *Weill Cornell Medicine/Center on Aging and Behavioral Research, New York, New York, United States*, 3. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Potentially harmful behaviors (PHB), such as wanting to scream at or hit a care recipient, are more likely when caregivers experience higher levels of stress. The current study expands on this research and identifies caregiving self-efficacy (SE) for dealing with disruptive behaviors as a mediator of the relationship between caregiver distress and PHB. Multilevel mediation models were tested using a sample of 244 caregivers of persons with dementia assessed three times over a one year period. In two separate models, SE mediated the relationship between caregiving burden/depression and the frequency of wanting to yell or scream at the care recipient in the past six months. Individuals with higher levels of depression and burden had lower levels of SE for dealing with disruptive behaviors. As SE decreased, the risk of potentially harmful behaviors increased. This mediation effect occurred at the within and between subject levels of the model. A significant indirect effect at the within-person level suggests that at timepoints where caregivers experienced more distress, they had lower self-efficacy and increased PHBs. Similar effects were observed at the between person level. These data suggest that both caregiver distress and self-efficacy are important intervention targets for minimizing PHBs.

COGNITIVE-BEHAVIORAL DEMENTIA CAREGIVING STYLES: ASSOCIATIONS WITH CARE STRESS AND WELL-BEING

Amanda Leggett,¹ Cathleen Connell,² Laura Gitlin,³ and Helen Kales,⁴ 1. *The University of Michigan, Ypsilanti, Michigan, United States*, 2. *University of Michigan School of Public Health, Ann Arbor, Michigan, United States*, 3. *Drexel University, College of Nursing and Health Professions, Drexel University, Pennsylvania, United States*, 4. *University of California, Davis, University of California, Davis, Sacramento, California, United States*

While Stress Process Models of family caregiving have been examined extensively, little focus has been placed on

caregiver's actual management of care. We consider whether caregiving style classified previously through k-modes machine learning models and based on cognitive-behavioral approaches to care impact caregivers' experiences of care-related stress and well-being. The three previously identified styles include: Adapters- strong dementia understanding and adaptability, encouraging behavioral approach; Managers- poor dementia understanding and adaptability, critical behavioral approach; and Avoiders- moderate dementia understanding and adaptability, passive behavioral approach. Participants included 100 primary family caregivers for PWDs who were on average 64 years old, 74% female, and 18% non-White. Utilizing linear regressions, each caregiving style was considered a key predictor (reference: Adapters) of the Zarit Burden Interview (ZBI), Caregiver Assessment of Function and Upset (CAFU) upset score, Neuropsychiatric Inventory (NPI-C) distress scale, and Positive and Negative Affect scale (PANAS) controlling for dementia severity, care duration, co-residency, and demographics. Relative to Adapters, Managers had more CAFU upset ($\beta=0.4$, $p<.001$), more NPI-C distress ($\beta=0.4$, $p<.001$), and greater burden (ZBI) ($\beta=0.3$, $p<.001$). Avoiders showed significantly greater CAFU upset than Adapters ($\beta=0.2$, $p<.05$). Positive affect was not associated with caregiving style. Caregiving styles associated with less understanding and adaptability and a more critical behavioral approach showed worse caregiving outcomes accounting for dementia severity. Results can inform a nuanced approach to tailoring and targeting interventions based on caregiver styles with the goal of reaching caregivers at risk for poor outcomes and ultimately leading to significant public health impact.

DAILY SLEEP, WELL-BEING, AND ADULT DAY SERVICES USE AMONG DEMENTIA CARE DYADS

Yin Liu,¹ Amanda Leggett,² Kyungmin Kim,³ Courtney Polenick,⁴ Susan McCurry,⁵ and Steven Zarit,⁶ 1. *Utah State University, Logan, Utah, United States*, 2. *The University of Michigan, Ypsilanti, Michigan, United States*, 3. *Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 4. *University of Michigan, Ann Arbor, Michigan, United States*, 5. *University of Washington School of Nursing, Seattle, Washington, United States*, 6. *Pennsylvania State University, Pittsburgh, Pennsylvania, United States*

Sleep is critical for health and well-being among both persons with dementia (PwD) and their family caregivers (CG). This study described sleep characteristics for dementia family care dyads, then examined the associations with sleep quality, daytime functioning, and mood in the context of Adult Day Services (ADS) use. Caregivers ($n = 173$) reported daily bedtime, wake time, and sleep quality for themselves and the persons with dementia across 8 consecutive days ($N = 1,359$), where PwD attended ADS at least 2 days of the week. They also reported their own fatigue and affect and PwD's daytime and nighttime sleep and behavior problems on each day. Findings from multilevel models suggested that bedtime was earlier and total time in bed was shorter before an ADS day for the dyad, and also on an ADS day for PwD; wake time was earlier for the dyad on and following an ADS day. Using ADS related to better prior night sleep quality for PwD; it also weakened the association between nighttime

sleep problems and higher daytime negative affect for CG. Yesterday's ADS use buffered the negative impact of shorter total time in bed on CG daytime fatigue; it also buffered the association between nighttime sleep problems and lowered CG daytime positive affect. Regular ADS use may protect against the adverse impact of sleep disturbances on daytime functioning and well-being for dementia care dyads.

FAMILY CAREGIVERS' FEELINGS OF PREPAREDNESS FOR THE TRANSITION TO END-OF-LIFE CAREGIVING

Aimee Fox,¹ Julia Sharp,² and Christine Fruhauf,² 1. *Kansas State University, Manhattan, Kansas, United States*, 2. *Colorado State University, Fort Collins, Colorado, United States*

Family caregivers are vulnerable to emotional, psychological, physical, and financial stress during their care receiver's end-of-life (EOL), and often do not have the knowledge or skills to provide the care needed at EOL. Yet, few studies have examined how prepared caregivers feel for making the transition to EOL care. The purpose of this exploratory study was to investigate how family caregivers perceive their preparedness for the transition to providing EOL care, and factors that may be associated with feelings of preparedness. Family caregivers (N = 252) providing care to an adult family member for more than six months were recruited to complete an online, self-report survey. An exploratory factor analysis was conducted to break down the construct of caregiver preparedness. One-way ANOVAs and a multiple regression were conducted to examine factors associated with preparedness. Most caregivers feel less prepared for the transition to EOL care (M = 2.67, SD = 1.17) than for general caregiving responsibilities (M = 3.42, SD = 0.90). Factors associated with preparedness for EOL caregiving included the familial relationship between the family caregiver and care receiver, hours per week providing care, perceived burden of caregiving, and family conversations completed about advance care planning, legal and financial matters, and EOL wishes. Future studies should explore how to help family caregivers recognize the importance of seeking support from family members and community services and discussing EOL care wishes and plans with aging family members so they can provide effective care and protect their own well-being.

GENDER-SPECIFIC PREDICTORS OF POOR SLEEP QUALITY AND INSOMNIA AMONG CAREGIVERS OF PERSONS LIVING WITH DEMENTIA

Glenna Brewster,¹ Miranda McPhillips,² Kate Yeager,³ Fayron Epps,³ Kalisha Bonds Johnson,³ Kenneth Hepburn,³ and Donald Bliwise,³ 1. *Emory University, Stonecrest, Georgia, United States*, 2. *University of Pennsylvania, University of Pennsylvania, Pennsylvania, United States*, 3. *Emory University, Atlanta, Georgia, United States*

Caregiving for a person living with dementia (PLwD) may influence sleep patterns. Gaps exist about whether caregiver and PLwD factors impact sleep differentially based on caregivers' gender. The aim of this secondary data analysis was to identify predictors of sleep quality and insomnia in a sample of caregivers, stratified by gender, participating in a randomized controlled trial of a psychoeducational intervention. Outcome measures were sleep quality (Pittsburgh Sleep

Quality Index, PSQI) and insomnia (Insomnia Severity Index, ISI). Participants (n=261) also completed measures about caregivers' perceived stress, burden, depression, and self-care, and PLwD's behaviors (i.e., apathy, sleep disorders). Linear regression modeling was used to identify the overall predictors of poor sleep quality (PSQI > 5; 52% of the sample) and insomnia (ISI > 7; 41% of the sample). Caregivers were primarily female (70.5%), White (73.6%), mean age of 64.6 (± 11.2) years, and typically caring for a spouse (65.9%). For male caregivers, predictors of poor sleep quality were assisting the PLwD with instrumental activities of daily living and PLwD neuropsychiatric symptoms (F=4.45, p<.001); while caregiver self-care and PLwD neuropsychiatric symptoms predicted insomnia (F=4.49, p<.001). For female caregivers, the predictors of poor sleep quality were caregiver depressive symptoms and burden, and frequency of PLwD behavioral problems (F=4.46, p<.001); however, only perceived stress predicted insomnia (F=4.32, p<.001). Various factors related to caregiving appear to be more important than others in predicting sleep outcomes of male/female caregivers. Health care professionals should acknowledge gender differences when designing and implementing programs and interventions to improve sleep.

PARENTING STYLE IN CHILDHOOD AND MENTAL HEALTH OUTCOMES OF CAREGIVING IN MIDDLE AND LATER ADULTHOOD

Yujun Liu,¹ M. Courtney Hughes,² and Abby Baumbach,² 1. *Northern Illinois University, Naperville, Illinois, United States*, 2. *Northern Illinois University, DeKalb, Illinois, United States*

Objectives. This study examined the association between remembered parenting style of both mothers and fathers in childhood and mental health outcomes of caregiving in middle and later adulthood. Methods. Data were from the Midlife in the United States (MIDUS) study, a national survey that included 7,108 participants aged 24 to 75 years at baseline. The sample analyzed in the current study included 244 MIDUS participants who had given personal care to their mothers or fathers for one month or more during the last 12 months in the second and third waves. Parenting style variables, which included maternal/paternal affection and maternal/paternal discipline, were from the first wave; mental health outcome variables, which included emotional distress, depressive symptoms, and life satisfaction, were from the second and third waves. Multiple regression and multilevel modeling were applied using R. Results. Maternal affection was negatively associated with emotional distress. Paternal affection was negatively associated with depressive symptoms. The associations between maternal/paternal discipline and mental health outcomes were not significant. Among the caregivers who provided care for parents, those who had mothers with high affection in childhood experienced a lower level of emotional distress, those who had fathers with high affection experienced a lower level of depressive symptoms in middle and later adulthood. Discussion. Our findings have advanced the understanding of the long-term consequences of parenting style in childhood on mental health outcomes among family caregivers in later life. The results have implications in the development of interventions focusing on mental health outcomes among family caregivers.

PREVALENCE OF BINGE DRINKING BY CAREGIVERS OF PERSONS WITH ALZHEIMER'S DISEASE OR RELATED DEMENTIA

Zachary Kunicki, and Richard Jones, *Brown University, Providence, Rhode Island, United States*

Some caregivers of persons with Alzheimer's Disease and related dementias (ADRD) are known to be under high levels of burden, which is associated with higher levels of anxiety, depression, and stress. Previous research has established anxiety, depression, and stress are associated with binge drinking, but little research has examined binge drinking rates among ADRD caregivers. Binge drinking could influence the ability of ADRD caregivers to provide care. The purpose of this study was to explore the prevalence and prevalence correlates of binge drinking among ADRD caregivers using the 2019 Behavior Risk Factor Surveillance Survey (BRFSS). We identified N = 1,642 persons who were the primary informal caregivers of a person with ADRD. Among them, the prevalence of binge drinking was 14 per 100 persons. Bivariable analyses suggested male caregivers and caregivers with 14 or more days of poor mental health in the past 30 days had the highest prevalence of binge drinking at 18 per 100 persons. Caregivers who were 65 or older or had the lowest prevalence at 3 per 100 persons. Caregiving characteristics revealed providing 20 to 39 hours of care per week had the highest prevalence of binge drinking (17 per 100) whereas spousal caregivers (9 per 100) had the lowest prevalence. Smoking status and hours per week providing care were associated with higher odds of binge drinking in multivariable analyses. Future research should examine if binge drinking by ADRD caregivers is related caregiver burden and the quality of care provided to the persons with ADRD.

RESILIENCE IN FAMILY CAREGIVERS OF ADULTS WITH AUTISM SPECTRUM DISORDER: AN INTEGRATIVE REVIEW OF THE LITERATURE

Daphne Chakurian, *University of Missouri - Columbia, Roseville, California, United States*

Care of adults with Autism Spectrum Disorder (ASD) is a public health priority and costs are projected to be 549 billion US dollars by 2025. Middle and older adult FCGs of adults with ASD often provide lifelong care, experience chronic stress, consequently, are at risk of poor mental health and QOL. An integrative review examined factors associated with resilience in studies of middle and older adult FCGs of adults with ASD. A comprehensive literature search found 10 reports of 8 studies published in peer-reviewed scholarly journals before October 13, 2020. Studies and/or reports of factors associated with resilience in middle and older adult FCGs of adults with ASD were examined using PRISMA, and quality checklists. Some 340 articles met search criteria, 14 were fully reviewed, and 10 were included. Findings suggest FCGs of adults with ASD show capacity for resilience consistent with research on FCGs of children with ASD significant chronic stress. A broad range of resilience factors were studied, and resilience was associated with positive social support, higher QOL, self-efficacy, and problem and meaning-focused coping styles. There is a dearth of research on middle and older adult FCGs of adults with ASD. Increased reporting of social determinants of health and participation of underrepresented groups is needed. Future

research must address FGC heterogeneity and specify theoretically grounded conceptual and operational definitions of resilience. Identifying resilience factors is necessary for intervention studies to enhance resilience.

SLEEP QUALITY IN FAMILY CAREGIVERS AND MATCHED NON-CAREGIVING CONTROLS: THE REGARDS STUDY

Marcela Blinka,¹ Adam Spira,² Orla Sheehan,³ Tansu Cidav,⁴ J. David Rhodes,⁵ Virginia Howard,⁶ and David Roth,¹ 1. *Johns Hopkins University, Baltimore, Maryland, United States*, 2. *Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*, 3. *Johns Hopkins University School of Medicine, Johns Hopkins University, Maryland, United States*, 4. *Johns Hopkins University School of Medicine, Baltimore, Maryland, United States*, 5. *University of Alabama at Birmingham, University of Alabama at Birmingham, Alabama, United States*, 6. *University of Alabama at Birmingham, Birmingham, Alabama, United States*

The high levels of stress experienced by family caregivers may affect their physical and psychological health, including their sleep quality. However, there are few population-based studies comparing sleep between family caregivers and carefully-matched controls. We evaluated differences in sleep and identified predictors of poorer sleep among the caregivers, in a comparison of 251 incident caregivers and carefully matched non-caregiving controls, recruited from the national REasons for Geographic and Racial Differences in Stroke (REGARDS) Study. Incident caregivers and controls were matched on up to seven demographic and health factors (age, sex, race, education level, marital status, self-rated health, and self-reported serious cardiovascular disease history). Sleep characteristics were self-reported and included total sleep time, sleep onset latency, wake after sleep onset, time in bed, and sleep efficiency. Family caregivers reported significantly longer sleep onset latency, before and after adjusting for potential confounders, compared to non-caregiving controls ($p < 0.05$). Depressive symptoms in caregivers predicted longer sleep onset latency, greater wake after sleep onset, and lower sleep efficiency. Longer total sleep time in caregivers was predicted by employment status, living with the care recipient, and number of caregiver hours. Employed caregivers and caregivers who did not live with the care recipient had shorter total sleep time and spent less time in bed than non-employed caregivers. Additional research is needed to evaluate whether sleep disturbances contributes to health problems among caregivers.

TELOMERE LENGTH AND THE TRANSITION TO FAMILY CAREGIVING IN THE REGARDS STUDY

William Haley,¹ Nicole Armstrong,² Ryan Irvin,³ Marcela Blinka,⁴ Rasika Mathias,⁵ Jeremy Walston,⁶ and David Roth,⁴ 1. *University of South Florida, Tampa, Florida, United States*, 2. *University of Alabama at Birmingham, University of Alabama at Birmingham, Alabama, United States*, 3. *University of Alabama at Birmingham, Birmingham, Alabama, United States*, 4. *Johns Hopkins University, Baltimore, Maryland, United States*, 5. *Johns Hopkins University, Johns Hopkins University, Maryland, United States*, 6. *Johns Hopkins University School of Medicine, Baltimore, Maryland, United States*

An increase in life expectancy and an aging population has resulted in increased risks and prevalence of age-related diseases. Previous studies have shown that factors, such as chronic stress, are associated with shorter telomere length. When telomeres become critically short, cells enter a state of senescence, which is a hallmark of aging. Several prior studies examining the relationship between caregiving and telomere length have reported mixed results. The present study utilized data from the Caregiving Transitions Study, an ancillary study to the Reasons for Geographic and Racial Differences in Stroke (REGARDS) study. The difference in telomere length across an average ~8.6 years was compared between 235 incident caregivers and 229 controls. Telomere length was determined using the qPCR telomere-to-single copy gene (IFNB1) ratio (T/S) for each participant at both baseline and follow-up timepoints. Regression models controlling for age, sex, race, and baseline telomere length examined the association between caregiving status (exposure) and the telomere length change (Δ T/S). Sensitivity models adjusted for potential lifestyle and socioeconomic factors, including income, education, BMI, cigarette smoking, and alcohol use. We did not observe a significant association between Δ T/S and caregiving ($\beta=0.041$, $p=0.615$). Adding lifestyle and socioeconomic factors did not change the null relationship ($\beta=0.062$, $p=0.455$). In conclusion, this study provides evidence against an association between caregiving and the change in telomere length. Ultimately, more research to address the complex relationship between caregiving and telomere attrition is needed in order to prevent or reduce adverse outcomes and improve the well-being of caregivers and care recipients.

Session 9295 (Poster)

Frailty

A NOVEL ALGORITHM FOR ANALYSIS OF MULTIPLE ENDPOINTS USING RISK-BENEFIT PROFILES

Natalia Gouskova,¹ Dae Kim,² Sandra Shi,³ and Thomas Trivison,² 1. *Hebrew SeniorLife, Marcus Institute for Aging Research, Hebrew SeniorLife, Boston, Massachusetts, United States*, 2. *Harvard Medical School, Boston, Massachusetts, United States*, 3. *Hebrew SeniorLife, Harvard Medical School, Roslindale, Massachusetts, United States*

Often it is necessary to evaluate effectiveness of an intervention on the basis of multiple event outcomes of variable benefit and harm, which may develop over time. An attractive approach is to order combinations of these events based on desirability of the overall outcome (e.g. from cure without any adverse events to death), and then determine whether the intervention shifts the distribution of these ordered outcomes towards more desirable (Evans, Follmann 2016). The win ratio introduced in Pocock et al 2012 was an earlier implementation of this approach. More recently Claggett et al 2015 proposed a more comprehensive method allowing nonparametric and regression-based inference in presence of competing risks. Key to the method is weighting observations by inverse probability of censoring (IPC) processes specific to participants and event types. The method has

seemingly great practical utility, but computation of weights is a non-trivial challenge with real-life data when each event can have its own censoring time. We present a novel recursive algorithm solving this problem for an arbitrary number of events ordered by clinical importance or desirability. The algorithm can be implemented in SAS or R software, and computes IPC weights, as well as nonparametric or parametric estimates and resampling-based measures of uncertainty. We illustrate the approach using data from the SPRINT trial of antihypertensive intervention, comparing risk-benefit profiles for robust, pre-frail, and frail subpopulations, and in analysis of fall as a function of progressive risk factors. More general use of the software tools deploying the method is described.

A NOVEL ELECTRONIC FRAILTY INDEX AS A PREDICTOR OF CLINICAL OUTCOMES AFTER TRANSCATHETER AORTIC VALVE IMPLANTATION

Maria Rangel,¹ Rahul Annabathula,² Nicholas Pajewski,³ Jeff Williamson,³ David Zhao,² and Kathryn Callahan,³ 1. *Wake Forest School of Medicine, Winston-Salem, North Carolina, United States*, 2. *Wake Forest Baptist Medical Center, Wake Forest School of Medicine, North Carolina, United States*, 3. *Wake Forest School of Medicine, Winston-Salem, North Carolina, United States*

Transcatheter aortic valve implantation (TAVI) is becoming the preferred therapeutic approach for older adults with severe aortic valve disease. Frailty portends increase mortality and adverse outcomes after TAVI. We sought to evaluate an electronic Frailty Index (eFI) as a predictor for increased healthcare utilization, adverse clinical and functional outcomes. We retrospectively studied 302 adults older than 65 years that underwent TAVI at our institution between October 2017 and September 2020. The mean age of the cohort was 79 ± 6.94 years old; 43% were female. Frail individuals ($eFI > 0.20$), as compared to Fit ($eFI < 0.10$) and Prefrail ($0.10 > eFI < 0.20$), were more likely to have a higher society of thoracic surgeons score and a greater burden of comorbidities. Subjects classified as Prefrail/Frail had longer intensive care unit stay post-TAVI than fit individuals (>24 hours: 17% vs 4%, respectively, $p 0.02$); and trended toward longer hospitalization time and discharge to a setting different than home. The Prefrail/Frail group also had a higher proportion of subjects with persistent New York Heart Association Class III heart failure symptoms 30 days post-TAVI as compared to Fit (14% vs 2%, $p 0.04$), however both groups demonstrated significant symptomatic improvement post-procedure. No significant differences in 30 day mortality, major adverse cardiovascular events or readmissions were found. TAVI is an effective treatment with a low incidence of early adverse clinical outcomes in older adults regardless of frailty status; eFI could help in identifying and targeting susceptible adults that may require additional resources to recover post-TAVI.

A RANDOMIZED PLACEBO-CONTROLLED TRIAL OF METFORMIN FOR FRAILTY PREVENTION IN OLDER ADULTS

Amir Tavabi,¹ Chen-pin Wang,² Joel Michalek,³ Tiffany Cortes,⁴ Ethan Leonard,⁵ Becky Powers,⁶ Nicolas Musi,³ and Sara Espinoza,¹ 1. *University of Texas Health Science Center San Antonio, San Antonio, Texas*,

United States, 2. UT Health San Antonio, UT Health San Antonio, Texas, United States, 3. UT Health San Antonio, San Antonio, Texas, United States, 4. University of Texas HSC at San Antonio, San Antonio, Texas, United States, 5. UT Health San Antonio - Barshop Institute, San Antonio, Texas, United States, 6. South Texas Veterans Health Care System, San Antonio, Texas, United States

Frailty is a progressive physical decline leading to higher morbidity and mortality in older adults. Previous studies have demonstrated shared mechanisms between insulin resistance, inflammation, and frailty. The purpose of this trial is to determine whether metformin prevents frailty in non-frail, community-dwelling older adults (≥ 65 years) with pre-diabetes, determined by 2-hour oral glucose tolerance test (OGTT). Frail individuals (Fried criteria) and those with renal impairment (glomerular filtration rate < 45 mL/min) are excluded. Eligible participants are randomized to metformin or placebo and followed for two years. The primary outcome is frailty; secondary outcomes include physical function (short physical performance battery), systemic and skeletal muscle inflammation (plasma and muscle inflammatory markers), muscle insulin signaling (muscle biopsy), insulin sensitivity (insulin clamp), glucose tolerance (OGTT), and body composition (dual-energy x-ray absorptiometry) measurements. Participants are followed every 3 months for safety assessments, every 6 months for frailty assessment and OGTT, and every 12 months for muscle biopsy. Currently, 99 participants, including 53 (53.5%) male and 91 (91.9%) white, are active (54) or have completed the study (35). At baseline, mean age was 72.3 ± 5.5 years, body mass index was 30.7 ± 5.9 kg/m², and Hemoglobin A1c was $5.73 \pm 0.37\%$. Mean frailty score was 0.5 ± 0.6 and the proportion of non-frail and pre-frail participants were 58.6% ($n = 58$) and 41.5% ($n = 41$), respectively. Findings of this clinical trial may have future implications for the use of metformin in older adults with pre-diabetes in order to prevent the onset of frailty.

ASSOCIATION OF FRAILTY INDEX WITH CLINICAL BPH PROGRESSION AND SERIOUS ADVERSE EVENTS: THE MTOPS TRIAL

Scott Bauer,¹ Kristine Ensrud,² Louise C. Walter,³ Anne M. Suskind,³ William A. Ricke,⁴ Teresa T. Liu,⁴ Kevin T. McVary,⁵ and Kenneth Covinsky,³ 1. UCSF and San Francisco VA, San Francisco, California, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States, 3. University of California, San Francisco, San Francisco, California, United States, 4. University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, United States, 5. Stritch School of Medicine and Loyola University Medical Center, Maywood, Illinois, United States

Lower urinary tract symptoms due to suspected benign prostatic hyperplasia (BPH) are increasingly treated with medications targeting obstruction among older men, but frailty may represent a novel risk factor for this condition. Our objective was to assess the associations between frailty and clinical BPH progression or serious adverse events (SAE) among 3047 men, age 50-89 years, enrolled in the Medical Therapy of Prostatic Symptoms Study, a placebo-controlled RCT of doxazosin, finasteride, or combination therapy on clinical BPH progression. We created a frailty index using 69 items collected at baseline and categorized men as fit (0-0.1), less fit (0.1-<0.25), or frail (0.25-1.0). The primary

outcomes were time to 1) first composite event of clinical BPH progression, and 2) SAE requiring hospitalization. Cox proportional hazards models were adjusted for demographics, intervention, BPH surrogates, and comorbidities. At baseline, 28% men were fit, 58% were less fit, and 14% were frail. During follow-up (mean 4.5 years), the incidence rate of clinical BPH progression was 2.2/100p-y among fit, 3.0/100p-y among less fit (HR =1.28, 95% CI 0.98, 1.67), and 4.1/100p-y among frail men (HR=1.60, 95% CI 1.13, 2.26). Among men randomized to combination therapy, the SAE incidence rate was 3.4/100p-y for fit men versus 12.7/100p-y for frail men (HR=5.98, 95% CI 3.76, 9.52). In conclusion, frailty is independently associated with greater risk of both clinical BPH progression and SAE. The decision to initiate medical therapy for BPH among frail men should therefore include a discussion of both benefits and risks via shared decision making.

BODY MASS INDEX AND FRAILTY AMONG OLDER MEXICAN AMERICANS: FINDINGS FROM AN 18-YEAR OF FOLLOW-UP

Megan Rutherford,¹ Brian Downer,¹ Chih-Ying Li,¹ and Soham Al Snih,² 1. The University of Texas Medical Branch, Galveston, Texas, United States, 2. University of Texas Medical Branch, Galveston, Texas, United States

The objective of this study was to examine body mass index (BMI) as predictor of frailty among non-frail Mexican American older adults at baseline. Data are from an 18-year prospective cohort of 1,647 non-institutionalized Mexican American aged ≥ 67 years from the Hispanic Established Population for the Epidemiologic Study of the Elderly (1995/1996-2012/13). BMI (Kg/m²) was grouped according to the National Institutes of Health obesity standards (< 18.5 =underweight, 18.5-24.9=normal weight, 25.0-29.9=overweight, 30.0-34.9=obesity category I and ≥ 35 =obesity category II and extreme obesity). Frailty was defined as meeting three or more of the following: unintentional weight loss of > 10 pounds, weakness, self-reported exhaustion, low physical activity, and slow walking speed. Covariates included socio-demographics, comorbidities, cognitive function, depressive symptoms, and limitations in activities of daily living (ADL). General Estimating Equations were performed to estimate the odds ratio (OR) and 95% confidence interval (CI) of frailty as a function of BMI categories. All variables were analyzed as time varying except for gender and education. Participants in the underweight or obesity type II / morbidity obesity category had increased OR of frailty over time than those in the normal weight category (2.68, 95% CI=1.46-4.9 vs. 1.55, 95% CI=1.02-2.35, respectively) after controlling for all covariates. Those who reported arthritis, hip fracture, depressive symptoms, or ADL disability had increased odds of frailty over time. This study showed a U-shaped relationship between BMI and frailty over an 18-year period of follow-up which has implications for maintaining a healthy weight to prevent frailty in this population.

COGNITIVE FRAILTY AND RISK OF FUNCTIONAL DISABILITY IN OLDER JAPANESE ADULTS: A 4-YEAR PROSPECTIVE STUDY

Sanmei Chen,¹ Takanori Honda,² Tao Chen,³ Hiro Kishimoto,⁴ Shuzo Kumagai,⁵ and Kenji Narazaki,⁶ 1. Graduate School of Biomedical and Health Sciences,

Hiroshima University, Hiroshima, Hiroshima, Japan, 2. Kyushu University, Fukuoka, Fukuoka, Japan, 3. Tongji University, Department of Physical Education, Tongji University, Shanghai, China (People's Republic), 4. Kyushu University, Kyushu University, Fukuoka, Japan, 5. Kumagai Institute of Health Policy, Kasuga City, Fukuoka, Japan, 6. Fukuoka Institute of Technology, Fukuoka, Fukuoka, Japan

Background: Cognitive frailty is a newly proposed clinical entity, referring to concurrent cognitive impairment and physical frailty in the absence of dementia. The clinical significance of cognitive frailty remains poorly understood. We aimed to investigate the association between cognitive frailty and functional disability in older adults. **Methods:** A total of 1,644 non-demented older adults aged ≥ 65 years (mean age: 73 ± 6 years; men: 41.8%) and without functional disability at baseline were followed-up for 4 years. Cognitive frailty was defined as the presence of both physical frailty (based on the modified Cardiovascular Health Study criteria) and cognitive impairment (Mini-Mental State Examination score of < 24 points). Functional disability was identified using the database of Japan's Long-term Care Insurance System. Association between cognitive frailty and functional disability was assessed by using the Cox proportional hazard models. **Results:** During the follow-up, 152 participants were identified as being functionally disabled. There was a significant interaction between physical frailty and cognitive impairment on the development of functional disability ($P < 0.1$). Compared with being robust both physically and cognitively, the hazard ratio (95% confidence interval) of functional disability was 8.40 (4.05-17.42) for cognitively frailty, after adjustment for age, sex, education, living alone, smoking, drinking, number of comorbidities (hypertension, stroke, chronic heart disease, diabetes, chronic kidney disease, poor hearing, poor vision, osteoarthritis or rheumatism, minor trauma fracture, or cancer). **Conclusion:** Cognitive frailty was associated with an increased risk of functional disability in community-dwelling older adults. Cognitive frailty could be an underrecognized risk factor for functional disability.

EFFECTIVENESS OF TRANSITIONAL CARE FROM HOSPITAL TO HOME IN FRAIL OLDER ADULTS: A SYSTEMATIC REVIEW

Ji Yeon Lee,¹ Yong Sook Yang,² and Eunhee Cho,³ 1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Yonsei University, Kwangju, Kwangju-jikhalsi, Republic of Korea, 3. Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea

Frail older adults are at high risk of negative consequences from hospitalization and are discharged without completely returning to their pre-existing health status. Transitional care is needed to maintain care continuity from hospital to home. This systematic review aimed to examine transitional care for frail older adults and its effectiveness. The Cochrane guidelines were followed, and search terms were determined by PICO: (P) frail older adults, not disease-specified; (I) transitional care initiated before discharge; (C) usual care; and (O) all health outcomes. Four databases were searched for English-written randomized controlled trials (inception to

2020), and eight trials were ultimately included. Frail older adults in eight trials (1996–2019) totaled 2,785, with a mean sample size of 310. The intervention components varied from hospital care (e.g., geriatric assessment, discharge planning, rehabilitation) to follow-up care after discharge (e.g., home visit, phone follow-up, community service). Most measured outcomes were readmission ($n = 7$), function ($n = 4$), quality of life ($n = 4$), self-rated health ($n = 3$), and mortality ($n = 3$). Statistical significance was reported in the following number of trials: readmission ($n = 2$), function ($n = 2$), quality of life ($n = 1$), self-rated health ($n = 3$), and mortality ($n = 0$). The effectiveness of the intervention on each outcome was inconsistent across the trials. Varied transitional care between hospital and home was implemented to improve health status; however, its effectiveness was controversial. A novel, yet evidence-based approach is needed to develop transitional care interventions for these vulnerable populations.

FRAILTY AND DEMENTIA: DIFFERENCES IN HEALTH CARE UTILIZATION AND COSTS

Stephanie Denise Sison,¹ Gahee Oh,² Sandra Shi,³ Brianne Olivieri-Mui,⁴ Ellen McCarthy,⁴ and Dae Kim,⁵ 1. Beth Israel Deaconess Medical Center / VA Boston New England GRECC, Boston, Massachusetts, United States, 2. Hinda and Arthur Marcus Institute for Aging Research, Roslindale, Massachusetts, United States, 3. Hebrew SeniorLife, Harvard Medical School, Roslindale, Massachusetts, United States, 4. Hebrew SeniorLife, roslindale, Massachusetts, United States, 5. Hebrew SeniorLife, Boston, Massachusetts, United States

Frailty and dementia are associated with poor health outcomes and increased health care utilization. A more nuanced understanding of this dynamic may be useful in improving care and developing policies. This retrospective cohort study was conducted using 5% random sample of Medicare fee-for-service beneficiaries ($n=1,132,367$; mean age 76.2 years; 57.9% female) in 2014-2016. We compared average 1-year home time (number of days alive outside of the hospital and SNF), mean total cost per beneficiary, and number of incident ICU stays per 100 person-years (PY) across four groups: frailty and dementia, dementia alone, frailty alone or neither. Frailty and dementia were identified using validated claims-based algorithms. We also determined differences in costs per group across different regions within the United States. Beneficiaries with both frailty and dementia had a high 1-year mortality rate of 21.9% (vs. dementia alone [9.7%], frailty alone [9.4%] or neither [2.1%]), while having less home time (306 days; difference of 36 days, 31 days, and 53 days, respectively), and more incident ICU stays per 100 PY (29.9 vs 9.5, 25.8, and 5.6, respectively). Mean total costs for beneficiaries with both was \$26,030 compared to other groups (\$12,096, \$24,693, and \$9,029, respectively). Across the United States, range of costs varied the most for beneficiaries with both frailty and dementia (\$13,244-31,987 vs \$4,621-15,364, \$20,090-30,965, and \$7,672-10,450, respectively). Increase in health care utilization and wide geographic variation in costs associated with patients with frailty and dementia suggests room for improvement in health care delivery to improve outcomes of this group.

FRAILITY AND FUNCTIONAL STATUS IMPROVE- MENT AFTER SKILLED NURSING FACILITY BASED POST-ACUTE CARE

Sandra Shi,¹ Brianne Olivieri-Mui,² Ellen McCarthy,² and Dae Hyun Kim,² 1. *Hebrew SeniorLife, Harvard Medical School, Roslindale, Massachusetts, United States*, 2. *Hebrew SeniorLife, roslindale, Massachusetts, United States*

People admitted to a skilled nursing facility (SNF) for post-acute care undergo comprehensive evaluation and rehabilitation, potentially enabling prediction of future functional recovery. We identified the first SNF admission per beneficiary (n=250,159) between 07/01/2014 – 06/30/2016 in a 5% Medicare sample, using the Minimum Data Set (MDS) and the Outcome and Assessment Information Set (OASIS). Episodes were excluded for non-community discharge (n=43,397) or no OASIS admission assessment within 14 days of SNF discharge (n=77,989). A deficit accumulation Frailty Index (FI) was measured on admission MDS assessment and categorized into robust (MDS-FI<0.15), pre-frailty (MDS-FI0.15-0.24), mild frailty (MDS-FI0.25-0.34), and moderate or worse frailty (MDS-FI≥0.35). Outcomes were functional decline obtained from OASIS, readmission, or death after initiation of home care. Functional status was measured by activities of daily living from OASIS assessments. A total of 135,310 SNF episodes were matched to OASIS episodes. Of these, there were 6,472 (4.8%) robust patients, 38,923 (28.8%) pre-frail, 63,727 (47.1%) mildly frail and 26,053 (19.3%) moderately frail or worse. In a logistic regression after adjustment for OASIS admission function, compared to robust status, frailty was associated with hospital readmission or death within 30 days of OASIS admission, (mild frailty OR1.33 [95%CI 1.23-1.45] and moderate or worse OR1.81 [95%CI 1.66-1.97]). Frailty was also associated with functional decline at OASIS discharge, after adjustment for OASIS admission function (mild frailty OR1.50 [95%CI 1.38-1.63] and moderate or worse OR2.30 [95%CI 2.11-2.50]). Among those discharged from SNF with home services, a SNF-based MDS-FI is associated with increased likelihood of poor community outcomes.

FRAILITY AND MACRONUTRIENTS INTAKE AMONG OLDER BRAZILIAN ADULTS

Carolina Freiria,¹ Grazielle Silva,² Larissa Hara,² Tábatá Brito,³ Flávia Arbex Silva Borim,¹ and Ligiana Corona,² 1. *University of Campinas, Campinas, Sao Paulo, Brazil*, 2. *University of Campinas, University of Campinas, Sao Paulo, Brazil*, 3. *Federal University of Alfenas, Federal University of Alfenas, Sao Paulo, Brazil*

The adequate nutrition has an important role in the prevent and treatment of frailty, however, there are only few studies showing the relationship between macronutrients intake and this geriatric syndrome, especially in Latin countries. The aim of this study was to analyze the association between macronutrients intake and frailty among older adults in Brazil. This study included 521 community-dwelling individuals aged 60 years old or older. Frailty was assessed using a self-reported instrument and individuals were categorized in two groups: frail and non-frail (robust + pre frail). Food consumption was evaluated using the 24-hour recall and the software NDSR®. Differences between groups was assessed using the Mann Whitney test. The prevalence of frailty

was 42.0%. Older adults considered frail presented lower intake of calories (1510.9 kcal vs 1639.3 kcal; p = 0.016), carbohydrates (196.8 g vs 213.3 g; p = 0.011), proteins (60.7 g vs 68.5 g; p = 0.016) and fiber (15.1 g vs 17.5 g; p= 0.002). They also had lower intake of protein per kilograms of weight (0.88 g/kg vs 0.99 g/kg; p= 0.010). The findings demonstrate high prevalence of frail in our sample, and that intake of most macronutrients was significantly lower among older adults with frail, indicating the importance of the screening of frail as well the evaluation of macronutrients intake among community-based older adults, to prevent malnutrition, sarcopenia and frailty in this population.

FRAILITY IN A FRAILITY PREVENTION PROGRAM PARTICIPANTS DURING COVID-19 PANDEMIC: A CROSS-SECTIONAL JAPANESE STUDY

Takuya Kanamori,¹ Mizue Suzuki,¹ Tomoyoshi Naito,¹ Keigo Inagaki,¹ and Hiroyuki Umegaki,² 1. *Hamamatsu University School of Medicine, Hamamatsu city, Shizuoka, Japan*, 2. *Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan*

Objective: Health conditions of older adults have deteriorated during the COVID-19 pandemic. Few studies have reported on the frailty of this group of people. The study aimed to investigate physical and social frailty in participants in a frailty prevention program during the COVID-19 pandemic. Methods: A cross-sectional survey was conducted in Japan from January 2021. Further, 863 participants of a frailty prevention program completed the survey. The frequency of program attendance in 2020, physical frailty (5-item frailty screening index), social frailty (diagnostic criteria of social frailty in NCGG-SGS), and depression (GDS-5) were assessed. A related factor of physical frailty was analyzed statistically by Welch's t test and the Chi-squared test. Results: The study participants' mean age, proportion of women, and mean enrollment period in program were 86.8±4.9, 96.3%, 64.3±48.6 months, respectively. The program attendance ratio was 83.4% from January to March, 54.5% from April to June, 79.8% from July to September, and 80.0% from October to December. The prevalence of physical frailty was 20.3% non-frailty, 63.7% pre-frailty, and 15.6% frailty. The prevalence of social frailty was 10.0% non-frailty, 28.6% social pre-frailty, 61.8% social frailty, and the prevalence of depression was 36.8%. Participants with physical frailty were significantly older and showed higher prevalence of social frailty and depression, displaying significantly lower attendance program than non-frailty and pre-frailty older adults (p<0.05). Conclusions: The study results suggest that more than half of the participants of a frailty prevention program have social frailty and a high risk of physical frailty due to COVID-19.

FRAILITY PREVALENCE AND ASSOCIATION WITH MORTALITY ACROSS BIRTH COHORTS IN SWEDISH REGISTRY DATA

Alexandra Wennberg, and Karin Modig, *Karolinska Institutet, Stockholm, Stockholms Lan, Sweden*

Frailty is associated with poor health outcomes, reduced quality of life, and mortality. To understand how prevalence of frailty may have changed across birth cohorts, we investigated frailty prevalence at ages 75, 85, and 95 in people

born in 1910, 1920, and 1930 in Swedish national registry data. Frailty was assessed with the Hospital Frailty Risk Score, a weighted sum of 109 ICD codes, which we calculated for each year leading up to the specified ages. We additionally investigated the association between frailty and mortality in these birth cohorts. We observed, at 75, a decrease in prevalence of frailty across birth cohorts (16.9%, 10.8%, and 8.8%, respectively). Interestingly, at 85, we found a U-shaped pattern, where those born in 1920 (14.1%) had lower prevalence of frailty than those born in either 1910 (27.7%) or 1930 (25.1%). At age 95, we saw a low prevalence of frailty in the 1910 (7.3%) and 1920 (3.8%) birth cohorts –potentially because of selective survival. There were not substantial differences in prevalence of frailty by sex or birth country. In Cox proportional hazard models adjusted for sex, frailty was consistently associated with mortality. We observed the greatest hazard ratios in the 1930 birth cohort at 75 (HR=2.79, 95% CI 2.62, 2.97) and 85 (HR=2.26, 95% CI 2.01, 2.53) and the 1920 birth cohort at 75 (HR=2.19, 95% CI 2.09, 2.29), where risk was double that of those who were not frail. Understanding changes in prevalence of frailty will help inform public health and intervention measures.

FUNCTIONAL TRAJECTORIES AND QUALITY OF LIFE IN POST-ACUTE SKILLED NURSING FACILITY CARE AFTER HOSPITALIZATION

Sandra Shi,¹ Brienne Olivieri-Mui,² Ellen McCarthy,² and Dae Hyun Kim,² 1. *Hebrew SeniorLife, Harvard Medical School, Roslindale, Massachusetts, United States*, 2. *Hebrew SeniorLife, Roslindale, Massachusetts, United States*

Frailty predicts readmissions and mortality after acute hospitalizations. Understanding whether frailty predicts functional recovery after acute hospitalizations may help guide post-acute care and rehabilitation. This feasibility study enrolled 24 adults aged ≥ 65 years from a skilled nursing facility (SNF) after acute hospitalization. We calculated a deficit-accumulation frailty index (FI range: 0-1; non-frail [≤ 0.25], mild frailty [0.26-0.35], moderate [0.36-0.45], and severe [>0.45]) via in-person assessment on SNF admission. We measured weekly functional improvement with modified Barthel Index, as well as quality of life. Modified Barthel Index and quality of life were measured weekly by Patient-Reported Outcome Measurement Information System (PROMIS) (standardized score with mean 50 and SD 10, higher is better). The mean age was 83.3 years [SD 8.0], and 17 (71.8%) were female. Length of stay for those with severe frailty (FI >0.45) was 26.8 days [10.7] compared to those who were not frail, mildly frail, or moderately frail (13.3 [7.3], 9.4 [4.4], and 15.2 [4.9] respectively). Those with severe frailty also had delayed functional improvement (mean Barthel Index 48.6, 53.4, and 56.6 on admission, week 1, and week 2 of SNF admission respectively), compared to those with moderate frailty (mean Barthel Index 47.5, 69, 73) or mild frailty (68.3, 86, 90.5). Self-reported mental and physical health-related quality of life was relatively unchanged across SNF episode for all frailty categories. These findings suggest that older adults with moderate or severe frailty may experience a typical course of delayed functional recovery and that further monitoring may be necessary for prognostication.

MALNUTRITION-SARCOPENIA SYNDROME AND ITS ASSOCIATED FACTORS AMONG OLDER ADULTS

Murad Taani, *University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, United States*

Malnutrition and sarcopenia are present in parallel in older adults and characterized by a combination of inadequate nutrient intake and decreased muscle mass, strength, and/or function. The presence of both conditions has been termed Malnutrition-Sarcopenia Syndrome (MSS) and is associated with negative health outcomes. The objective of this correlational study was to identify the prevalence and factors associated with the malnutrition-sarcopenia syndrome among older adults living in continuing care retirement communities. A convenience sample of 104 older adults living in CCRCs participated in this study. Muscle mass, strength, and function were measured using bioimpedance analysis, Jamar digital hand dynamometer, and the Short Physical Performance Battery test, respectively. Physical activity, sedentary time, and nutritional status were measured using ActiGraph GT3X and Mini Nutritional Assessment, respectively. Questionnaires were used to measure self-efficacy for exercise and goal congruence for physical activity and protein intake. Of the 104 participants, 37 (35.2%) had sarcopenia, 19 (18.1%) had malnutrition, and 14 (13.5%) had MSS. Compared with those without MSS, older adults with MSS were more than two times more likely to have a sedentary lifestyle (Odd ratio, 2.028; 95% confidence interval, 2.012–2.044). Findings showed that sarcopenia, malnutrition, and MSS are prevalent in older adults living in continuing care retirement communities. Older adults should be screened and assessed for both malnutrition and sarcopenia. The results also suggest that decreasing the sedentary time could help in preventing MSS among older adults living in continuing care retirement communities.

OUTCOMES OF A TELEPHONE-BASED FRAILTY AND FUNCTIONAL ASSESSMENT

Stephanie Denise Sison,¹ Karla Tejada Arias,² Natalie Newmeyer,³ Racheli Schoenburg,² Carolina Fonseca Valencia,⁴ and Dae Kim,⁵ 1. *Beth Israel Deaconess Medical Center / VA Boston New England GRECC, Boston, Massachusetts, United States*, 2. *BIDMC, Boston, Massachusetts, United States*, 3. *Marcus Institute for Aging Research, Boston, Massachusetts, United States*, 4. *BIDMC, Providence, Rhode Island, United States*, 5. *Hebrew SeniorLife, Boston, Massachusetts, United States*

With the goal of increasing the clinical use of frailty, we piloted a quality improvement project to determine the feasibility and utility of a telephone-based frailty and functional assessment. We identified 122 established patients with serious medical illness from an academic geriatrics clinic. A geriatric fellow assessed the functional status and conducted the Mini Nutritional Assessment, telephone-MoCA, and Geriatric Depression Scale to generate a deficit-accumulation frailty index (FI) score which was automatically calculated through the electronic medical record. A note was then generated to inform the providers of the details of the assessment and to provide recommendations based on the findings. From November 2020 to March 2021, 104 out of 122 (85.2%) established patients (mean [SD]: 83.4 [7.1], 66% female, 81% White, and mean [SD] FI: 0.32 [0.17]) agreed and proceeded

with the assessment. One month after the call, we found that the assessment was included in the clinical decision-making of 55 out of 100 patients seen by their primary care provider. The top 3 incorporated recommendations were chronic disease management based on frailty status (n=56), life-style change and counseling to prevent frailty progression (n=44), and management of cognition and mood (n=18). Management of physical status including referral to PT and OT were incorporated in 15 encounters. Our results suggest that a telephone-based frailty and functional assessment is feasible and has value-added contributions in improving the care of older adults through providing a holistic view of their health status.

PHYSICAL FRAILTY AND COGNITIVE IMPAIRMENT IN OLDER NURSING HOME RESIDENTS: A LATENT CLASS ANALYSIS

Yiyang Yuan,¹ Kate Lapane,² Jennifer Tjia,³ Jonggyu Baek,² Shao-Hsien Liu,² and Christine Ulbricht,² 1. *University of Massachusetts Chan Medical School, Burlington, Massachusetts, United States*, 2. *University of Massachusetts Medical School, University of Massachusetts Medical School, Massachusetts, United States*, 3. *UMass Chan Medical School, University of Massachusetts Medical School, Massachusetts, United States*

Physical frailty (PF) has various clinical presentations and often co-occurs with cognitive impairment in older adults. In older adults in nursing homes (NHs), no research has examined the heterogeneous profile of PF and its association with cognitive impairment. Minimum Data Set 3.0 was used to identify older, long-stay, newly-admitted NH residents (2014-16; n=871,801). Latent class analysis was used to identify PF subgroups with FRAIL-NH items as indicators. Logistic regression was used to estimate the association between PF subgroups and cognitive impairment. The final model indicated three PF subgroups (prevalence): “mild PF” (7.6%), “moderate PF” (44.5%), and “severe PF” (47.9%). In all subgroups, residents had high probability of needing help with dressing. Older adults likely to belong to the “moderate PF” or the “severe PF” subgroups had high probabilities of requiring physical assistance to transfer between locations and inability to walk in a room. Additionally, residents likely to be in the “severe PF” subgroup had greater probability of bowel incontinence. Greater cognitive impairment was associated with increasingly higher odds to be in the “moderate PF” and “severe PF” subgroups: older residents with severe cognitive impairment were 20% more likely [adjusted odds ratio (aOR): 1.20, 95% confidence interval (CI): 1.17-1.23] and almost 7 times as likely (aOR: 6.86, 95%CI: 6.66-7.06) to belong to the “moderate PF” and “severe PF” subgroups, respectively. Findings provide new evidence for the interrelationship between PF and cognitive impairment in older NH residents and have implications for the development of interventions tailored to older residents’ specific PF experience.

PHYSICAL FRAILTY IS CORRELATED WITH WORSE QUALITY OF LIFE IN OLDER ADULTS WITH HYPERTENSION

Pan Liu, Yaxin Zhang, Shijie Li, Ying Li, Yumeng Chen, Ou Zhao, Yun Li, and Lina Ma, *Xuanwu Hospital, Capital Medical University, National Research Center*

for Geriatric Medicine, Beijing, Beijing, China (People's Republic)

Background: Hypertension is one of the commonest chronic cardiovascular diseases in older adults. Frailty and hypertension often coexist in older people, but few studies have explored frailty in older hypertensive adults. We aimed to explore the correlation of frailty with quality of life in older hypertensive adults. Method: We enrolled 291 patients with hypertension aged ≥ 60 years. Ambulatory blood pressure monitor was performed. Physical frailty was assessed by Fried phenotype. Quality of life was assessed by SF-36. Results: Forty-eight (16.5%) patients were frail. Compared with non-frail older hypertensive patients, frail patients were older, had lower education levels, a higher rate of living alone, and a longer duration of hypertension. Moreover, they had lower diastolic blood pressure (DBP) and mean arterial pressure (MAP), and higher pulse pressure, more chronic diseases, a higher proportion of calcium channel blockers (CCBs) usage, and worse quality of life. Frailty scores were positively correlated with pulse pressure, and negatively correlated with DBP and MAP. The SF-36 score was negatively correlated with frailty scores and positively correlated with grip strength and walking speed. After adjusting for age, the SF-36 score was negatively correlated with frailty and positively correlated with walking speed. Frailty, when adjusted for age, duration of hypertension, DBP and comorbidity, had a significant effect on the SF-36 score. Conclusion: Frailty was associated with worse quality of life of older adults with hypertension. Frailty prevention and intervention may help improve the quality of life of older hypertensive adults. Keywords: frailty, older adults, hypertension, quality of life

PROMOTING EARLY ASSESSMENT OF FRAILTY IN THE NEW NORMAL: AN UPDATED EFI-CGA SOFTWARE TOOL

Katayoun Sepehri,¹ Hilary Low,² Grace Park,³ and Xiaowei Song,² 1. *University of British Columbia, Vancouver, British Columbia, Canada*, 2. *Surrey Memorial Hospital, Surrey, British Columbia, Canada*, 3. *Fraser Health, Surrey, British Columbia, Canada*

Frailty is a state of diminished physiological reserves. Being able to detect and manage frailty early is crucial for effective controlling of frailty-related adverse outcomes. Frailty can be assessed using the frailty index that counts the number of health deficits accumulated over time. Our previous research has enabled an electronic Comprehensive Geriatric Assessment (eCGA) and the calculation of the frailty index based on the eCGA (eFI-CGA). While the standalone eFI-CGA has been used by primary care providers in assessing home-living patients, its initial release was prior to the covid-19 pandemic; the associated new challenges were not targeted by the early version. In facilitating effective virtual assessment and care planning during the current “lockdown” and in the upcoming “new normal”, most recently the eFI-CGA version 3.0 was released. In this paper, we 1) introduce the updated electronic frailty assessment tool and its usage, 2) describe the major updates of the software in dealing with challenges due to social isolation and remote assessment, and 3) evaluate the end-user experience with the upgraded methods in frailty assessment. These new developments and implementations allowed a search

function to resume disrupted assessment sessions and quickly retrieve previously saved assessment records. The improved user interface promoted the clinicians to conveniently record detailed care plans and management details. The study provided a successful example of moving from disruption to transformation, benefiting the highly demanded healthcare of older adults in this challenging time.

RISK FACTORS ASSOCIATED WITH COGNITIVE FRAILITY AMONG COMMUNITY-DWELLING OLDER ADULTS: A SCOPING REVIEW

Sumi Lee, and JuHee Lee, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Objectives: This study aimed to explore the risk factors associated with cognitive frailty (CF) among community-dwelling older adults, and to provide the impact of CF on health-related outcomes. **Methods:** PubMed, EMBASE, Cochrane, PsycINFO, CINAHL, RISS, DBpia, NDSL, and KoreaMed databases were searched to retrieve studies. Two reviewers independently screened titles, abstracts and articles. The inclusion criteria are peer-reviewed articles written in English or Korean for community-dwelling older adults with both physical frailty and cognitive impairment present at the same time. **Results:** A total of 3,513 were searched, and the final 33 were extracted according to the inclusion criteria. Physical factors affecting CF were the number of chronic disease, cardiovascular disease, activity of daily living (ADL), making telephone calls and shopping during instrumental ADL, and a Mini Nutrition Assessment–Short Form score. Psychological factor was depressive symptoms. Significant behavioral factors included self-reported physical activity, low vitamin D, smoking, frequent insomnia, and sedentary lifestyle. In social factors, social participation such as volunteering was identified as a protective factor. Mortality, followed by dementia was health related outcomes on CF, including ADL dependence, poor quality of life, and hospitalization. However, the CF-related fall was inconsistent. **Conclusion:** A wide variety of factors have been presented in studies related to CF. In order to understand CF and improve health-related outcomes, older adults in CF should be screened as high-risk group. When the risk factors and protective factors of CF managed, better health-related outcomes will lead to successful aging of community-dwelling older adults.

SKELETAL MUSCLE QUALITY OF NONAGENARIANS AND CENTENARIANS

Iva Miljkovic,¹ Adam Sterczala,¹ Emma Barinas-Mitchell,¹ Ryan Cvejkus,¹ Mary Feitosa,² Bharat Thyagarajan,³ Mary Wojczynski,⁴ and Joseph Zmuda,¹ *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. Washington University School of Medicine in St. Louis, St. Louis, Missouri, United States, 3. University of Minnesota, Minneapolis, Minnesota, United States, 4. Washington University School of Medicine, Washington University School of Medicine, Missouri, United States*

Skeletal muscle adipose tissue infiltration is hypothesized to lead to poorer muscle quality and function with aging. Indeed, skeletal muscle adiposity has emerged as a consistent, independent predictor of skeletal muscle strength, mobility, metabolic disorders, and survival among older adults.

However, phenotypic features of skeletal muscle among the oldest-old remain poorly characterized. Herein, we evaluated the skeletal muscle characteristics of 54 nonagenarians and centenarians (mean age 98 years, range 90–110 years; 63% women) and 25 middle-aged individuals (mean age 54 years, range 40–59 years; 36% women) belonging to the Long Life Family Study (LLFS), an international, multicenter cohort of families with a clustering of longevity. Ultrasonography was used to measure echo intensity of the sternocleidomastoid muscle, which has a similar fiber type distribution to the rectus femoris. Greater echo intensity is indicative of lower muscle quality (greater adipose and fibrotic tissue). Current smoking, alcohol intake, and BMI were similar between the age groups. Nonagenarians and centenarians had lower grip strength (16.3 vs. 39 kg) and were less physically active (22.2% vs 66.7% exercised 1+ times per week) compared to younger individuals ($P < 0.001$ for all). Mean \pm SE echo intensity, adjusted for gender, field center, BMI and physical activity was 52.1 ± 1.7 among nonagenarians and centenarians compared to 44.2 ± 2.4 among younger individuals ($P = 0.0098$). Our preliminary findings suggest that nonagenarians and centenarians may have substantially lower skeletal muscle quality and strength compared to their younger aged counterparts. Additional research is needed to better understand the mechanisms leading to poorer muscle characteristics of the oldest-old.

THE EFFECT OF LOW-DOSE ASPIRIN ON FRAILITY IN OLDER ADULTS IN THE ASPIRIN IN REDUCING EVENTS IN THE ELDERLY STUDY

Sara Espinoza,¹ A R M Saifuddin Ekram,² Robyn Woods,³ Michael Ernst,⁴ Galina Polekhina,³ John McNeil,³ Anne Murray,³ and Joanne Ryan,³ *1. University of Texas Health Science Center San Antonio, San Antonio, Texas, United States, 2. Monash University, Monash University, Melbourne, Victoria, Australia, 3. Monash University, Melbourne, Victoria, Australia, 4. University of Iowa, Iowa City, Iowa, United States, 5. Hennepin HealthCare Research Institute, Hennepin HealthCare, Minneapolis, Minnesota, United States*

There are no widely accepted pharmacologic treatments for frailty prevention. Since frailty is associated with inflammation, aspirin has the potential to reduce frailty. We investigated whether low-dose aspirin reduces incident frailty in participants of the ASPIrin in Reducing Events in the Elderly (ASPREE) trial. In the U.S and Australia, 19,114 healthy community-dwelling individuals aged ≥ 70 years (U.S. minorities ≥ 65 years) were enrolled in ASPREE, a double-blind, placebo-controlled trial of 100mg daily low-dose aspirin vs. placebo. Frailty was defined according to a modified Fried frailty definition, and a frailty index which used a deficit accumulation model. Competing risk Cox proportional hazards models were used to compare time to incident frailty for aspirin vs. placebo. At baseline, 2.2% and 8.1% met criteria for frailty by Fried and frailty index criteria, respectively. Over a median of 4.7 years of follow-up, 2252 participants developed incident frailty according to Fried classification, and 4376 according to the frailty deficit accumulation index. There was no difference in the risk of incident frailty between individuals randomized to aspirin versus placebo according to either criteria (Fried frailty HR: 1.03, 95% CI 0.97–1.09,

p=0.41; frailty index HR: 1.03, 95% CI 0.97-1.10, p=0.29). Change in frailty over time was not different between the aspirin and placebo treatment arms. The results were consistent across a series of sub-groups, including baseline frailty status. Based on these results, aspirin use in healthy older adults does not reduce incident frailty.

Session 9300 (Poster)

Geriatric-Focused Education and Training

CLINICAL GERIATRICS AS A TEAM SPORT: FOSTERING INTERPROFESSIONAL EXPERIENCES IN THE COMMUNITY

David Picella, and Diana Woods, *Azusa Pacific University, Azusa, California, United States*

Team-based care is necessary to provide better healthcare outcomes for the complex needs of older adults. Shared clinical learning experiences prepare practitioners to work in collaborative partnership to achieve optimal outcomes. To promote collaborative partnership, we established interprofessional community based clinical experiences with older adults at home, in assisted living and in skilled nursing facilities. One nurse practitioner faculty member was paired with 2 students for each clinical experience day. Initially these were face-to-face encounters, however, with the onset of COVID-19, all high-risk encounters were converted to a virtual modality. The clinical encounters focused on the Age Friendly Model (4M). Post clinical discussions and recommendations focused on interprofessional treatment plans. A REDCap(TM) survey was completed by all student participants for program evaluation. Of the 14 surveys sent, 11 were completed; 10 (77%) females; 3 (23%) males; 7 (50%) family practitioner students; 7 (50%) adult-gerontology nurse practitioner students. Four had previous home health experience (14%), and 10 had none (86%). 4M Likert scale (1-5) means were “what matters” = 4.27, medications = 4.18, mentation = 4.09, and mobility = 4.09. Students found the overall experience valuable (mean = 4.27). Of 11 students, 3 (27%) were involved telehealth experiences. Students found real community based clinical experiences to be very enlightening, offering a different perspective, and altering their appreciation for the everyday life of the older adult. Future plans include adding social work and physical therapy students to these clinical experiences to enhance interprofessional education.

EFFECTIVENESS OF THE DEMENTIA NURSING COMPETENCE E-LEARNING PROGRAM FOR NURSES IN ACUTE CARE HOSPITALS IN JAPAN

Mizue Suzuki,¹ Tetsuro Ishihara,² Nanayo Sasaki,³ Hiromi Yoshimura,⁴ Ikuko Sakai,⁵ Kimiyo Mastushita,⁶ Soichiro Mimuro,⁷ and Keisuke Sawaki,⁸ 1. *Hamamatsu University school of medicine, Hamamatsu, Shizuoka, Japan*, 2. *Ishihara NeuroCognitive Clinic, seidai, Miyagi, Japan*, 3. *Hamamatsu University Hospital, Hamamatsu, Shizuoka, Japan*, 4. *Institute for Graduate Nurses of Japanese Nursing Association, Tokyo, Tokyo, Japan*, 5. *Graduate School of Nursing Chiba University, Chiba, Chiba, Japan*, 6. *Seirei Mikatabara General Hospital,*

Hamamatsu, Shizuoka, Japan, 7. *Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan*, 8. *Hamamatsu Shugakusha Junior High School & High School, Hamamatsu, Shizuoka, Japan*

Objective: The number of older patients with dementia hospitalised in acute care hospitals increased and these patients underwent physical restrictions leading to a degeneration of essential mental and physical function. The dementia nursing competence e-learning program with audio-visual materials has been developed in acute care hospitals. Methods: An application form that explained the research was distributed to 1,944 registered nurses from seven hospitals, and 110 people applied. Nurses used an e-learning program for a month in May and practiced applying the knowledge learned from programs June through November 2020. The nurses completed a questionnaire survey at four periods: first (before program/baseline), second (after program), third (three months later), and fourth (six months later). In the second, third, and fourth periods, ‘Technical knowledge of the dementia nursing’ and ‘dementia nursing intervention’ were significantly improved as compared with the first. In the fourth period, ‘confidence of reduce of physical restriction’ showed significant improvement compared to the first. In ‘Ethical sensitivity scale of nurses’, the first of the four sub-scales significantly increased as compared with the first period. In ‘Self-assessment Scale of Nursing Practice for Elderly Patients with Cognitive Impairment with the Aim of Person-centred Care in Acute Care Hospitals’, the fourth sub-scale showed significant improvement compared to the first. In the ‘Personhood’ sub-scale of the Japanese version of Approaches to Dementia Questionnaire, the fourth period showed a significant increase compared to the first. Conclusion: The results suggest that this program was effective and led to reduced physical restrictions in nursing practice.

END OF LIFE VIRTUAL REALITY TRAINING: MEDICAL STUDENT INCREASED EMPATHIC ABILITY

Marilyn Gugliucci,¹ Daniel Manukhin,² Elizabeth Dyer,² and Barbara Swartzlander,² 1. *University of New England College of Osteopathic Medicine, Kennebunk, Maine, United States*, 2. *University of New England, University of New England, Maine, United States*

Introduction: It is unclear if medical student empathy declines by third year of clinical rotation trainings. Desensitization throughout the first two years may lead to decreases in empathy as a coping mechanism to avoid burnout in the clinical years. This study determined if self-assessed empathy increased after conducting an Embodied Labs, Inc. end of life virtual reality (VR) experience. Methods: Mixed methods, quantitative/qualitative, research were applied for University of New England (UNE) College of Osteopathic Medicine (COM) 2nd year medical students (N=174). They completed the 3-part 30 minute Clay Lab VR experience. UNE IRB approved pre/post-tests focused on empathy. Data were collected using RedCap. Closed questions were analyzed applying frequency analysis and paired-sample t-test through excel. Open-ended questions were analyzed through N-VIVO 12+. Results: The data included pre/post-tests from 146 students volunteers. Results indicated statistical significance (P=.01) in all closed questions except for question 7

(What is your view of conducting a full code on a patient with a DNR? ($P=.14$). The greatest difference seen between pre (23.97% agree or strongly agree) and post-test (64.38% agree or strongly agree) data was for question 3 (I gained knowledge about what hospice is by embodying Clay in this virtual reality lab); $P=.00$. Three qualitative themes included: Impact, Empathy, EOL Knowledge. Conclusion: This VR Lab experience increased self-assessed empathy at the time of Clay Lab completion; however, enduring empathy and learning about hospice/EOL has not been measured. Further research is suggested to determine the longitudinal impact of virtual reality education.

EXPERIENCE OF PHYSICAL THERAPY STUDENTS MENTORING OLDER ADULTS WITH HEALTH LITERACY TOOLS

Mary Milidonis,¹ Jane Keehan,² Katherine Montgomery,³ Rebecca Deuley,² Sara Formoso,² and Karen Kopera-Frye,⁴
 1. Cleveland State University, Hudson, Ohio, United States, 2. Cleveland State University, Cleveland, Ohio, United States, 3. Cleveland State University, Cleveland State University, Ohio, United States, 4. New Mexico State University, Las Cruces, New Mexico, United States

Health literacy is a top priority for Healthy People 2030. Healthy People 2030 defines personal health literacy as “the degree to which individuals have the ability to find, understand, and use information and services to inform health-related decisions and actions for themselves and others.” The purpose is to understand the experience of physical therapy students using health literacy tools with older adults to promote the adoption of health literacy tools in healthcare encounters. This project analyzes the reflection responses from students using qualitative methods. The qualitative methods included student reflection papers, word clouds, and focus groups. Twelve students participated in focus groups/ reflections. Thirty-seven students participated in word clouds. Health literacy tools included plain language, teaching teach back and “Ask me 3”[®]. Students were taught by student leaders and faculty about the meaning of health literacy and oral communication tools. Pairs of students provided health education with health literacy tools to older adults. Students then participated in a small group reflection to create word clouds. Students answered questions and provided five words that best answer each question. Students believed the benefits of health literacy tools for older adults includes better learning, participation and engagement. Reasons to use health literacy in the future were improved older adult independence, education and adherence. Students completed reflections and interviews at the end of the year to detail their experience with the health literacy tools. The pedagogical approach highlighted the value of experiential learning for the students while mentoring older adults.

GERIATRIC KNOWLEDGE GAPS OF COMMUNITY-BASED PROVIDERS: A NATIONAL STUDY OF ASKED QUESTIONS

Lee Lindquist,¹ Aylin Madore,² Stephanie Miller,² Alice Kerr,³ and Sara Bradley,³ 1. Northwestern University Feinberg School of Medicine, Chicago, Illinois, United States, 2. DBC Pri-Med, LLC, Boston, Massachusetts, United States, 3. Northwestern University Feinberg School

of Medicine, Northwestern University Feinberg School of Medicine, Illinois, United States

Primary care providers (PCP) - internists, family practitioners, nurse practitioners, physician assistants - play an integral role in the care of older adults, although many receive limited geriatrics education. We sought to examine what questions community-based PCPs had about geriatrics and clinical care of older adults. As part of large clinical continuing medical education (CME) conferences across 12 states (FL,GA,CA,IL,NY,MA,DC, PA,AZ,TX,TN,WA), PCPs attended a live in-person 60-minute geriatrics-focused lecture and entered questions into a mobile application. Questions were then qualitatively analyzed using constant-comparison and tie-break methodology. At all sites, 103 questions were asked with 158 upticks (PCPs could check off that they had similar question) with a range of 3-18 questions per lecture. PCPs asked questions on the following common themes: 1.) Medication-related (e.g. discontinuing medicines in asymptomatic patients, optimizing pain relief), 2.) Dementia (e.g. prevention, nutraceuticals, agitation) 3.) Medicare Coding 4.) Falls 5.) Weight loss, and 6.) Insomnia. There were a number of questions referencing incorrect practices (e.g. prescribing inappropriate medications such as benzodiazepines for sleep, placement of gastric tubes in late-stage dementia, antibiotics to treat asymptomatic bacteria). In conclusion, community-based PCPs nationally experience gaps in geriatric knowledge and several utilize practices that could jeopardize older adult health. While attending CME-based lectures is one means of overcoming these gaps, some PCPs may not find time or realize geriatrics as an educational need. PCPs need to be better supported with opportunities to ask geriatric care-related questions in order to improve the care of older adults.

HOW 4MS AGE-FRIENDLY CARE LED TO IMPROVED COMPLIANCY OF OLDER ADULT FALL SCREENINGS IN RURAL PRIMARY CARE CLINICS

Leah Tobey, and Robin McAtee, University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States

Past medical history of falls and fear of falling are reliable indicators of future fall risk of an older adult (OA). As one of the HRSA funded Geriatric Workforce Enhancement recipients, the AR Geriatric Education Collaborative (AGEC) worked with a rural federally qualified healthcare clinic system to help incorporate fall screens to satisfy the Mobility factor in the 4Ms age-friendly care framework. After consultation with the practitioners, it was decided to use the Timed-Up-And-Go (TUAG) screen because it is evidence-based and appropriate for OAs. Training on the use of the TUAG was completed next as was the addition of the screen into the EMR. Fall screens in one clinic were only completed 7% before training and 7 months after the training, this rose to almost 100%. In a second clinic, the screens were completed 22% of the time and this was increased to 66% after training. Training on mobility continues to occur on a regular basis as staff turns over and as new priorities arise, but the use of the TUAG as a mobility screen has been a critical component in the process of these rural clinics providing age-friendly care. Next steps with improving fall risks will be the development of flags within the EMR that will force practitioners to complete a full falls plan of care if the OA scored within the

moderate or high fall risk categories. The plan will include home safety education and/or evaluation, PT or OT referrals to further support healthy aging for the OA.

IMPLEMENTATION OF 4M AGE-FRIENDLY CARE IN ARKANSAS RURAL PRIMARY CARE CLINICS LED TO IMPROVED ADVANCE CARE PLANNING

Leah Tobey, and Robin McAtee, *University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*

The 4Ms Age-Friendly Framework has been introduced and implemented into nearly 2,000 primary care practices across the United States by Geriatric Workforce Enhancement Program's (GWEP) educational efforts. The AR Geriatric Education Collaborative, the GWEP in Arkansas, has provided monthly trainings to a rural federally qualified healthcare clinic system and educated clinicians about how to complete a Medicare Annual Wellness Visit (AWV) that was inclusive of an advance care plan. Specific educational training including the two main components of an ACP: living will preferences and medical power of attorney were reviewed as their role into "What Matters" was explained. Before 4Ms Age Friendly training, baseline data showed only 7% of older adults (OAs) had an established ACP in site 1 and 33% in site 2. After training, the rate of ACP rose to 47% in site 1 and 59% in site 2. During the training, not only were the two main components reviewed but case studies were provided about what questions to ask surrounding the "What Matters" question as a guide to further discuss an OAs wishes, priorities and end-of-life care. This project demonstrated that implementation of 4Ms Age-Friendly Care not only improves the completion of advance care plans but also further enhances the overall care of the older adult when "what matters" most to the older adults is known and communicated.

MEDICAL/PHARMACY STUDENTS INTERPROFESSIONAL OLDER ADULT MEDICATION INTERACTIONS/CONTRAINDICATIONS PROJECT

Marilyn Gugliucci,¹ and Victoria Thieme,² 1. *University of New England College of Osteopathic Medicine, Kennebunk, Maine, United States*, 2. *University of New England College of Osteopathic Medicine, University of New England, Maine, United States*

The University of New England College of Osteopathic Medicine (UNECOM) Geriatrics Education Mentors [GEM] program, established in 2014, pairs UNECOM students with older community living adults. GEM assignments focus on health review, medical humanities, and geriatrics training. Each year approximately 90 older adults participate in GEMs. In 2019, the GEM program was expanded with Geriatrics Workforce Enhancement Program (GWEP) grant funding to: include first year medical students, include 2 additional assignments (4 assignments over 10 months to 6 assignments over 18 months), and to create interprofessional student collaboration. In the new GEM Assignment 4: Medication Interactions/Contraindications, UNECOM students with their GEM compiled details on the GEM's medication list (prescriptions, herbal, OTC); one of 4 Ms of Age Friendly Health Care. UNECOM students (84 pairs) were then assigned to UNE School of Pharmacy (SOP)

students (42 SOP students had 2 UNECOM pairs) to conduct a "Lexicomp" (App) medication interactions and Beers Criteria review. UNECOM students documented findings with the SOP student partner; discussed the processes of review with their GEM and the resultant findings; documented the GEM's questions and how the UNECOM student answered those questions; and discussed next steps for the GEM regarding options for different medications - especially follow up with their prescribing physician(s) for any noted interactions/contraindications. For GEMs with few medications, a mock medication list was assigned to ensure student experiences with medication reviews and GEM discussion. Although time intensive preparation is required, UNECOM & SOP students attained significant learning as did the GEM mentors.

RECOGNIZING AND RESPONDING TO ELDER MISTREATMENT: DEVELOPING AND TESTING AN ONLINE TRAINING FOR EMS PRACTITIONERS

Kristin Lees Haggerty,¹ Melanie Miller,² Dana M. Wardlaw,³ Randi Campetti,³ Athi Myint-U,⁴ and Brad Cannell,⁵

1. *Education Development Center, West Roxbury, Massachusetts, United States*, 2. *Education Development Center, Jamaica Plain, Massachusetts, United States*, 3. *Education Development Center, Waltham, Massachusetts, United States*, 4. *Education Development Center, Education Development Center, Massachusetts, United States*, 5. *University of Texas Health Science Center at Houston, Dallas, Texas, United States*

Elder mistreatment is an urgent and under recognized public health concern with devastating consequences for older adults, families, and health systems. Risk for elder mistreatment has increased during the COVID-19 pandemic, further highlighting the urgency to address it. Prehospital emergency medical service (EMS) practitioners have unique opportunities to recognize signs of elder mistreatment but often lack the training and tools required to facilitate consistent identification and intervention. To address this gap, Education Development Center collaborated with a team of expert advisors and EMS practitioners to develop and pilot test Recognizing and Responding to Elder Mistreatment: An Online Training for EMS Practitioners with funding from the RRF Foundation for Aging. This training aims to prepare EMS practitioners to recognize potential mistreatment and report suspected elder mistreatment in line with state laws and their professional code of ethics. In this presentation, we will describe the iterative development process, present results from a pilot test conducted with EMS practitioners in Massachusetts and share strategies and progress for disseminating the training nationally. The pilot study utilized a pre-post design to assess changes in knowledge, attitudes, and practices at baseline, immediately after and two months following participation in the training. Results indicate statistically significant improvements in knowledge related to elder mistreatment identification and response from pre- to post-training and maintenance of these improvements two months later. Participants reported feeling more prepared to address elder mistreatment in their work as EMS practitioners and applying their new knowledge and skills during the two months following the training.

THE 4MS IN A PANDEMIC: A SURVEY OF TRAINING NEEDS AMONG HEALTHCARE PROFESSIONALS, OLDER ADULTS, AND COMMUNITY MEMBERS

Jennifer Crittenden,¹ Abigail Elwell,² David Wihry,² and Lenard Kaye,² 1. *University of Maine, University of Maine, Maine, United States*, 2. *University of Maine, Bangor, Maine, United States*

The University of New England, in collaboration with the University of Maine, received a five-year grant from the Health Resources and Services Administration (HRSA) to improve the health and well-being of Maine's older adults through enhanced training under HRSA's Geriatrics Workforce Enhancement Program (GWEP). As part of these efforts, stakeholder training needs assessment data were collected via a statewide electronic survey that was distributed to community members and providers throughout Maine. The survey, which focused on the 4M's of Age-Friendly Healthcare, received 68 responses from older adults/community members (N = 26), program administrators (N = 12), along with community leaders, and those working in the public and non-profit sector (N = 13). A significant emphasis on social isolation, mental health, and grief and loss issues was noted and dominating themes centering on two dimensions of the 4M framework: "What Matters" and "Mentation." Findings reflect an overriding priority by providers and consumers to keep older adults socially connected (28%, N = 34) and maintaining mental health and well-being during the pandemic (21%, N = 14). Qualitative response analysis identified additional COVID-19-related training topics such as: what to do if you or a loved one contracts coronavirus, how to handle grief and loss related to COVID-19, strategies for supporting loved ones during COVID-19, and socially distanced bereavement support. Results indicate a need to focus on meeting the emotional and mental health needs of older adults, as well as the importance of encouraging connections and mitigating the effects of social isolation during COVID-19.

USING THE 4 M OF THE AGE FRIENDLY HEALTH SYSTEM TO IMPROVE MIPS DOCUMENTATION IN PRIMARY CARE: A FEASIBILITY STUDY

Sweta Tewary,¹ Denise Kruszynski,² Naushira Pandya,³ Nicole Cook,³ Sashah Damier,¹ and Assma Twahir,³ 1. *Nova Southeastern University, Fort Lauderdale, Florida, United States*, 2. *NSU, Davie, FL, Florida, United States*, 3. *NSU, Davie, Florida, United States*

Age Friendly Health Systems (AFHS) commit to evidence-based, low-risk, coordinated care that is centered on what matters most to older adults, their families and caregivers. Nova Southeastern University South Florida Geriatric Workforce Enhancement Program (NSU SFGWEP) has partnered with multiple primary care clinics to provide dedicated AFHS training and support to increase AFHS transformation in Broward and Miami-Dade Counties. As part of the initiative, SFGWEP provide didactic training, clinic on-site brief demonstration, and infographic guidance for EHR documentation. NSU SFGWEP activities are conducted through training surveys, provider feedback, and e-clinical measures that align with CMS MIPS measures. Three participating health systems report annually on seven e-clinical measures that, collectively, provide indicators of the 4Ms of AFHS

(what matters, medication management, mentation and mobility.) From baseline to Year 1, NSU SFGWEP saw improvement in controlled hypertension (54% to 94%), opioid screening (<1% to 11%), advance care planning (21% to 35%) and falls risk assessment (45% to 59%). Results demonstrate the need to continue and expand AFHS interventions for sustainability. In Year 2, SFGWEP will continue to expand awareness of best practices and benefits of the AFHS through education and training at NSU and at the various primary care sites. As mutual collaboration and implementation methods are shared among participating members, the expectation is that quality healthcare of our elder community adults will measurably improve.

Session 9305 (Poster)

Geroscience

AGE, SEX, AND CEREBRAL MICROBLEEDS AFFECT WHITE MATTER INTEGRITY ACROSS ADULTHOOD AFTER MILD TRAUMATIC BRAIN INJURY

David Robles,¹ Ammar Dharani,¹ Nikhil Chaudhari,¹ Kenneth Rostowsky,² Layal Webbe,¹ Michelle Ha,¹ Van Ngo,¹ and Andrei Irimia,² 1. *University of Southern California, Los Angeles, California, United States*, 2. *University of Southern California, University of Southern California, United States*

The contributions of age, sex, and cerebral microbleeds (CMBs) to WM changes after mild traumatic brain injury (mTBI) have not been studied. We used diffusion tensor imaging (DTI) to map WM fractional anisotropy (FA) changes across the first ~6 months post-mTBI in 109 subjects aged 18-77 (46 females; age μ : 40 y, σ : 17 y) imaged within ~1 week post-injury and ~6 months later. After partialing out age, sex, and CMB counts, significant mean FA decreases were found in the anterior body, posterior body, and splenium of the corpus callosum (CC; $p = 0.003, 0.009$ and 0.015 , respectively), left superficial frontal fasciculus ($p = 0.008$), and left branch of the corticospinal tract (CST; $p = 0.007$). Age contributed to mean FAs measured acutely in the CC body ($p = 0.04$), and chronically in the CC genu ($p < 0.001$), CC body ($p = 0.01$), and middle longitudinal fasciculi ($p = 0.04$), older adults exhibiting larger decreases. CMB counts were positively associated with mean FA decreases in the CC body ($p = 0.04$) and middle longitudinal fasciculi ($p = 0.04$). Significant age-by-sex and CMB count-by-age interactions mediated FA decreases in the CC genu ($p = 0.02$ and $p = 0.03$, respectively), older males exhibiting larger decreases. Thus, the CC, longitudinal fasciculi, superficial frontal WM and CST are particularly vulnerable to post-traumatic neurodegeneration moderated by age, sex and CMB count, men and older adults being at highest risk for adverse effects. Future research should investigate our findings relative to cognitive function.

AGE-RELATED AORTIC STIFFNESS CAN BE TRANSFERRED AND AMELIORATED VIA FECAL MICROBIOTA TRANSPLANT IN MICE.

Nathan Greenberg,¹ Nicholas VanDongen,² Rachel Gioscia-Ryan,² Abigail Casso,² David Hutton,² Zachary Clayton,² Douglas Seals,² and Vienna Brunt,² 1.

University of Colorado at Boulder, Boulder, Colorado, United States, 2. University of Colorado Boulder, Boulder, Colorado, United States

Age-related increases in aortic stiffness contribute to the development of cardiovascular diseases (CVD). To determine whether the gut microbiome (GM) modulates age-related aortic stiffening, we performed fecal microbiota transplants (FMT) between young (Y; 3 month) and older (O; 25 month) male C57BL/6N mice. Following antibiotic treatment (to suppress endogenous microbiota), mice received weekly FMT (fecal samples collected at baseline) via oral gavage for 8-16 weeks from their own (i.e., sham condition: Y-y, O-o [RECIPIENT-donor]) or opposite age group (Y-o, O-y) (N=8-12/group). In vivo aortic stiffness (pulse wave velocity [PWV]) was higher in older vs. young mice at baseline (382 ± 8 vs. 328 ± 7 cm/sec, mean \pm SE, $P < 0.001$). Arterial phenotypes were transferred such that old microbiota transplanted into young mice increased, while young into old decreased, PWV (Y-y: 325 ± 10 vs. Y-o: 362 ± 10 cm/sec, $P = 0.022$; O-o: 409 ± 10 vs. O-y: 335 ± 6 cm/sec, $P < 0.001$). Intrinsic mechanical stiffness of excised aortic rings (elastic modulus) increased after transplant of old into young (Y-y: 2141 ± 223 vs. Y-o: 3218 ± 394 kPA, $P = 0.022$), and decreased with young into old (O-O: 3263 ± 217 vs. O-y: 2602 ± 136 kPA, $P = 0.016$), indicating the GM mediates aortic stiffening by modulating structural changes in the arterial wall. Age-related increases in aortic abundance of advanced glycation end products (AGEs), which cross-link arterial structural proteins, tended to be transferred by the GM (Y-y: 0.022 ± 0.001 vs. Y-o: 0.038 ± 0.006 A.U., $P = 0.11$; O-o: 0.120 ± 0.029 vs. O-y: 0.038 ± 0.009 A.U., $P = 0.06$). The aging GM can induce aortic stiffening via promoting AGEs accumulation and crosslinking of arterial structural proteins, and thus might be a promising target for preventing/treating age-related aortic stiffening and CVD.

GEROSCIENCE APPROACHES TO OBESITY

Alessandro Bitto, and Matt Kaeberlein, University of Washington, Seattle, Washington, United States

Besides aging, obesity is the greatest risk factor for numerous chronic pathologies, including metabolic syndrome, type 2 diabetes, cardiovascular disease, hypertension, and cancer. Preventing and treating obesity would greatly reduce healthcare costs and the impact of the aging process, with estimated savings up to \$145,000,000,000. Pharmacological interventions identified by geroscience may prove effective against diet-induced obesity. To test this hypothesis, we fed a 66% kcal/fat diet to nine-month-old C57Bl6/N mice for 6 weeks and treated them with either rapamycin, acarbose, or a combination thereof. Rapamycin, and to a lesser extent acarbose, prevented weight gain and fat accumulation in these mice. We detected increased expression of the Liver Activating Protein (LAP) isoform of the transcription factor CCAT/Enhancer Binding Protein β (C/EBP β) in the liver of mice treated with rapamycin. C/EBP β -LAP mediates some of the effects of caloric restriction on nutrient metabolism and increases lifespan in a mouse transgenic model. We tested whether independent activation of C/EBP β -LAP would recapitulate the effects of rapamycin by treating mice on a high-fat diet with adefovir dipivoxil, a reverse transcriptase inhibitor that can activate LAP in vitro independently of

mTOR inhibition. Adefovir dipivoxil reduced weight and fat mass accumulation in mice over the course of 6 weeks. Mice treated with adefovir dipivoxil showed increased expression of genes involved in β -oxidation and lipids mobilization, and reduced activation of fatty acid biosynthesis and lipid storage pathways. Our results identify C/EBP β -LAP as a potential new target to improve lipid homeostasis in both aging and obesity.

PRE-OPERATIVE PHYSICAL FUNCTION PREDICTS POST-OPERATIVE SKELETAL MUSCLE GENE EXPRESSION IN OLD MICE

Samantha Asche-Godin,¹ Lauren Harlow,² Zachary Graham,³ Weihua Huang,⁴ Charles Mobbs,⁵ Christopher Cardozo,² and Fred Ko,² 1. Icahn School of Medicine at Mount Sinai/James J. Peters VA Medical Center, Bronx, New York, United States, 2. James J. Peters VA Medical Center, Bronx, New York, United States, 3. Birmingham VA Medical Center, Birmingham, Alabama, United States, 4. New York Medical College, Valhalla, New York, United States, 5. Icahn School of Medicine at Mount Sinai, New York, New York, United States

In older adults, pre-operative physical function predicts post-operative outcomes. The biological mechanisms underlying vulnerability to physical decline remain poorly understood. Using a mouse model of laparotomy, we sought to identify biological correlates of post-operative function. 24-month-old male C57BL/6N mice were categorized as high functioning (HF) or low functioning (LF) based on pre-operative performance on the accelerating rotarod. On post-operative days (POD) 2 and 4, LF mice had lower rotarod latency to fall times than HF mice did. Forelimb grip strength was reduced after laparotomy in both HF and LF groups on POD 1 and 3 and did not differ significantly between these groups. Whole transcriptome sequencing analysis (RNAseq) of soleus muscles collected on POD 5 showed 224 and 228 differentially expressed genes (DEGs) for HF and LF, respectively, compared to their respective controls. Only 21 DEGs were observed in both groups, including Ppar α , Fst and Pla2g15. Such changes may be hallmarks of the post-surgical response in aging. Pathway analysis of DEGs using Ingenuity Pathway Analysis software (Qiagen) revealed one pathway common to HF and LF (osteoarthritis) whereas activation of GP6 signaling and apoptosis signaling was observed in HF and inhibition of PPAR α /RXR activation and PPAR α signaling was noted in LF. We conclude that pre-operative performance on the accelerating rotarod correlates with differences in skeletal muscle gene expression, which may contribute to the differences in functional outcomes post-operatively in HF and LF mice. Further studies are needed to delineate the roles of these signaling pathways in physical resilience to surgery.

SEX AND AGE DIFFERENCES IN DEFAULT MODE NETWORK FUNCTIONAL CORRELATION AFTER TRAUMATIC BRAIN INJURY

Anar Amgalan,¹ Alexander Mayer,¹ Michelle Ha,¹ and Andrei Irimia,² 1. University of Southern California, Los Angeles, California, United States, 2. University of Southern California, University of Southern California, California, United States

The extent to which brain functional correlations (FCs) are modulated by age and sex is unknown. We studied default mode network (DMN) FC changes in 136 participants with mild traumatic brain injury (mTBI; 52 females, age range: 19 – 79 years, age μ = 42, age σ = 17; 72 participants younger than 40). Structural and functional magnetic resonance images (MRIs) were acquired ~1 week and ~6 months post-injury; the FreeSurfer Functional Analysis Stream (FS-FAST) was used for group-level FC comparisons across sexes and age groups (younger vs. older than 40). FC seeds were two sub-networks of the DMN, M1 and M2, defined by the standard Yeo parcellation scheme. For M1, clusters with significant FC differences across sexes were in the right paracentral lobule, central sulcus, postcentral gyrus, superior frontal gyrus, and precentral sulcus ($p = 0.0001$), and in the left paracentral lobule and central sulcus ($p = 0.022$). For M2, clusters spanned the right postcentral gyrus, middle occipital gyrus, transverse occipital sulcus, and central sulcus ($p = 0.0001$), the left precuneus and inferior parietal lobe ($p = 0.0096$). Females either exhibited no significant FC change or underwent FC increases. Males underwent significant FC decreases within all clusters, suggesting their increased vulnerability to mTBI-related effects. Clusters whose FCs differed significantly across age groups were localized to the left superior temporal gyrus ($p = 0.0078$), highlighting the vulnerability of temporal regions to age effects. Future studies should explore the age \times sex interaction and uncover the mechanisms for these observed findings.

THE ROLE OF OBESITY IN FRAILTY INCIDENCE: THE SAN ANTONIO LONGITUDINAL STUDY OF AGING

Tiffany Cortes,¹ Chen-pin Wang,² Helen Hazuda,² and Sara Espinoza,³ 1. *University of Texas HSC at San Antonio, San Antonio, Texas, United States*, 2. *UT Health San Antonio, UT Health San Antonio, Texas, United States*, 3. *University of Texas Health Science Center San Antonio, San Antonio, Texas, United States*

Background: Although initially conceptualized as a wasting syndrome, obesity has been associated with frailty in prior studies. The goal of this study was to examine the associations of obesity and waist circumference with frailty and determine whether they predict incident frailty in an ethnically diverse population of older Mexican Americans (MAs) and European Americans (EAs). Methods: 749 MA and EA community-dwelling older adults (65+) participated in the baseline examination of the San Antonio Longitudinal Study of Aging (SALSA), and 474 participants completed the first follow up approximately 6 years later. Frailty was classified using Fried criteria. Baseline characteristics, including body mass index (BMI) and waist circumference (WC) were summarized by frailty category (non-frail, pre-frail, frail) using ANOVA. The odds of becoming frail at follow-up by baseline BMI and WC were estimated using separate logistic regression models, adjusting for age, sex, ethnicity, diabetes, comorbidity (presence of ≥ 2 chronic diseases not including diabetes), baseline frailty score, and follow-up time. Results: At baseline, participants were 69 ± 3 years old, 61% female, and 50% MA. BMI and WC increased with increasing frailty category ($p < 0.01$ for both). BMI was a significant predictor of incident frailty (OR=1.08, 95% confidence interval [CI]: 1.02-1.14, $p=0.011$). WC also predicted frailty (OR=1.03,

95% CI: 1.01-1.05, $p = 0.017$). Conclusion: These results demonstrate that BMI and WC are significant predictors of frailty. Interventions which target obesity may reduce the incidence of frailty; however, more research in this area is needed.

Global Aging

Session 9310 (Poster)

CENTENARIANS IN THE GLOBAL SOUTH: A VIEW FROM ETHIOPIA

Samson Chane,¹ and Margaret Adamek,² 1. *Bahir Dar University, Bahir Dar, Oromiya, Ethiopia*, 2. *Indiana University, INDIANAPOLIS, Indiana, United States*

As global aging advances, the number of centenarians worldwide is greatly increasing. Most of what is known about centenarians comes from the Global North. It is not clear what factors contribute to longevity of centenarians in impoverished, mostly rural areas of Global South nations that still lack basic amenities. Cultural differences in the profile, lifestyles, and needs of centenarians in Africa have yet to be documented. Using a case study design, this descriptive inquiry investigated the profiles of centenarians in Ethiopia including religion, marriage, education, occupation, income, and living arrangement. Data were generated through in-depth interviews with nine centenarians (1 woman, 8 men) and were analyzed using descriptive narrative analysis. Respondents were between 100 and 108 years old. All nine were adherents of Orthodox Christianity, had been married, and were great-grandparents. Their adult lives were marked by both residential and marital stability. The Ethiopian centenarians persevered through many losses and hardships with the help of strong community-based social networks. Unlike studies of centenarians in the Global North, most respondents were male and had strict religious upbringings. Understanding the unique profiles of centenarians in the Global South will help to inform research and practice with this growing population of the oldest-old.

COMPARISON OF CATASTROPHIC OUT-OF-POCKET MEDICAL EXPENDITURES IN THE US AND SOUTH KOREA

Narae Kim, and Mireille Jacobson, *University of Southern California, Los Angeles, California, United States*

To date, relatively few studies have examined catastrophic out-of-pocket medical spending in the United States, especially in comparison to other high-income countries. We compared catastrophic out-of-pocket medical spending among adults age 65 and older in the United States versus South Korea, a high-income country with national health insurance that is often overlooked in cross-country comparisons. We defined catastrophic medical spending as health care expenditure for the past two years that exceeds 50% of one's annual household income. Using data from the 2016 Health and Retirement Study (HRS) and Korean Longitudinal Study of Aging (KLoSA), we performed a logistic regression to examine the factors affecting catastrophic out-of-pocket medical spending for older adults in both countries. We also performed a Blinder-Oaxaca decomposition to compare the

contribution of demographics factors versus health system-level factors to catastrophic out-of-pocket medical spending. The proportion of respondents with catastrophic out-of-pocket medical expenditure was higher in the US; the proportion was 5.8% and 3.0% in the US and South Korea, respectively. Both in the US and South Korea, respondents who were in the lower-income quartiles, who had experienced a stroke or had diabetes, and who rated their health as poor had higher odds of catastrophic out-of-pocket medical expenditure. The Blinder-Oaxaca non-linear decomposition showed that the significant difference in the rate of catastrophic out-of-pocket medical spending between the two countries was attributable to unobservable system-level factors, not observed differences in the sociodemographic characteristics between the two countries.

NON-RESPONSE TO POPULATION AGING IN SUB-SAHARAN AFRICA: A SURVEY OF GERONTOLOGY SCHOLARS

Margaret Adamek,¹ Messay Kotecho,² Samson Chane,³ and Getachew Gebeyaw,⁴ 1. *Indiana University, INDIANAPOLIS, Indiana, United States*, 2. *Addis Ababa University, Addis Ababa, Adis Abeba, Ethiopia*, 3. *Bahir Dar University, Bahir Dar, Oromiya, Ethiopia*, 4. *University of Gondar, Gondar, Oromiya, Ethiopia*

Life expectancy is increasing globally, with the biggest gains expected in sub-Saharan Africa. In fact, most of the population growth globally in the next few decades will occur in sub-Saharan Africa. Using an online survey we investigated the perspectives of gerontology scholars on the challenges of aging in sub-Saharan Africa as well as the assets of elders. Respondents (n=72) from 17 countries, primarily in Africa, and representing 16 disciplines, identified the top issues facing African elders as: poverty, lack of trained professionals, food insecurity, disability/health issues, and long-term care. Older adults' unique strengths were noted as indigenous knowledge systems, being holders of cultural heritage, and their contributions to development. Respondents' biggest concerns about older adults in sub-Saharan Africa were the lack of government attention to aging issues (63%) and a lack of social services targeted to elders' needs (57%). Government funding (77.8%) and international partnerships (38.9%) were noted as resources needed to support aging research in sub-Saharan Africa. The response or non-response of governments in sub-Saharan Africa will determine whether the growing number of older adults will increasingly experience unmet needs and whether their assets will be considered in development efforts. Establishing professional networks of gerontology scholars in the region will help to document the challenges faced by elders, to plan for the coming demographic shift, and to empower elders to thrive as valued community members.

OLDER CANCER SURVIVORS LIVING WITH FINANCIAL HARDSHIP IN CHINA: THE INFLUENCE OF CONFUCIAN FAMILY VALUES

Mingzhu Su, Li Liu, Hanlin Yue, Jiajun Zhang, and Nengliang Yao, *Shandong University, Jinan, Shandong, China (People's Republic)*

Background: Financial hardship has not been well studied among older cancer survivors, despite its debilitating effects on their health and well-being. Aim: To describe the lived

experience of older Chinese cancer survivors and explore the financial impacts following a cancer diagnosis. Design: A qualitative study conducted using semi-structured interviews with patients and family caregivers. Methods: We individually interviewed twenty-one cancer survivors (aged \square 60) with financial hardship and twenty family caregivers in Shandong province between August 2020 and January 2021. A content analysis was performed by multiple coders. Findings: Confucianism culture and the Chinese health system considerably impact the construct of financial hardship and its components. Four main categories were revealed: (1) healthcare providers were reluctant to discuss the diagnosis and costs of care with cancer patients; (2) financial transfer from adult children to older parents became prevalent after a cancer diagnosis; (3) cancer-related financial worries and stress spilled out into children's family; (4) coping and adjustment strategies were taken by the extended family. Conclusion: Both older cancer survivors and their adult children experienced financial distress mediating through filial piety in China. Instruments are needed to screen for cancer-related financial hardship adapted to the healthcare system and Confucian family values. Key words: Cancer survivors; older; financial hardship; qualitative; China

ORGANIZATIONAL PRACTICES FOR THE AGING WORKFORCE: VALIDATION OF AN ENGLISH VERSION OF THE LATER LIFE WORKPLACE INDEX

Julia Finsel,¹ Anne Wöhrmann,² Mo Wang,³ Max Wilckens,¹ and Jürgen Deller,⁴ 1. *Leuphana University Lüneburg, Lüneburg, Niedersachsen, Germany*, 2. *Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Nordrhein-Westfalen, Germany*, 3. *University of Florida, Gainesville, Florida, United States*, 4. *Leuphana University of Lüneburg, Leuphana University of Lüneburg, Niedersachsen, Germany*

Due to aging workforces, research on organizational practices for older employees becomes more important for individuals and organizations. However, existing measures for such organizational practices tend to capture the construct with unidimensional scales, use single-item operationalizations, or focus on a specific area. Hence, Wöhrmann, Deller, and Pundt (2018) developed the Later Life Workplace Index (LLWI) to provide a multidimensional framework to measure organizational practices for older employees on nine dimensions, namely organizational climate, leadership, work design, health management, individual development, knowledge management, transition to retirement, continued employment after retirement, and health and retirement coverage. The LLWI has recently been operationalized and validated in Germany (Wilckens, Wöhrmann, Deller, & Wang, 2020). However, to utilize the index beyond German-speaking countries, a validated English version is required. Thus, we aimed to validate an English version of the LLWI using a sample of older U.S. employees (N = 279). Results support the domain level factor structure of the LLWI but show some redundancy among the 80 items for the overall nine domain factor structure. A comparison between the U.S. sample and a German sample (N = 349) confirmed configural and (partial) metric measurement invariance of the English version. Results further supported convergent, discriminant, criterion, as well as incremental validity. Researchers can utilize the new measure

to gain a deeper understanding of organizational practices relevant for older employees, while practitioners are able to assess their organizational readiness for an aging workforce. We envision further translation and validation in other languages and cultural contexts.

PERCEPTIONS OF GENERATIONAL CONFLICT AMONG THREE AGE GROUPS IN SOUTH KOREA

Ahyoung Lee,¹ Soondool Chung,² and Juhyun Kim,³

1. *Ewha Womans University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Ewha Womans University, Ewha Womans University, Seoul-t'ukpyolsi, Republic of Korea*, 3. *Chungnam National University, Daejeon, Taejeon-jikhalsi, Republic of Korea*

After rapid industrialization during the past few decades, the gap between generations in South Korea has widened and the issue of generational conflict is being discussed as a social problem (Chung & Lim, 2018). The purpose of this study is to find out how each generation perceives generational conflict in the areas of family, politics, economy and social welfare, and culture. An online survey of 1,000 adults aged 20 and over was conducted nationwide in South Korea in January, 2021 with three age groups: the youngest group aged 20-39, mid-age group of 40- 64 and the oldest group of 65 and over. The questionnaire was created using the items developed by a previous research that used a Delphi technique (Chung, 2020). Participants answered how serious they perceive generational conflict in the dyadic relationship on 5-point Likert scales. Descriptive statistics were calculated, and t-tests have been performed to see the generational differences. Results show that the youngest group and the oldest group perceive the highest level of generational conflict each other in the areas of culture and politics. In cultural aspects, 'use of slang among the same group', 'Ability to utilize digital devices' were the items that had the highest level of conflict. In the political realm, progressive vs. conservative ideology was the area of the highest conflict. In addition, t-test results showed that the oldest group perceived generational conflict even deeper than the youngest group in the 'economy and social welfare' and cultural areas. Implications of these findings are discussed.

POLICY DESIGN AND CONSUMER DIRECTION: CROSS-COUNTRY COMPARISONS ON CONSUMER-DIRECTED CARE PROGRAMS

Jinbao ZHANG,¹ Julia Shu-Huah WANG,² and Yu-Chih Chen,³

1. *University of Hong Kong, Hong Kong, Hong Kong*, 2. *The University of Hong Kong, Hong Kong, Hong Kong*, 3. *University of Hong Kong, Pok Fu Lam, Hong Kong*

Objectives: The consumer-directed care (CDC) program aims to maximize health outcomes by offering older adults more control, choice, and flexibility over the care services they received. However, countries may operate CDC programs in different ways based on heterogenous sociostructural systems. We proposed a comparative framework to evaluate three dimensions of CDC—control and direct services, variety of service options, and information and support—and analyzed how countries varied in their policy design to achieve consumer direction. Methods: Using cross-national document analysis, we analyzed eleven CDC programs from seven

selected countries (Netherlands, United States (US), United Kingdom (UK), Germany, China, Australia, and Spain) with five CDC care regimes. A total of fourteen indicators capturing three dimensions of CDC programs was developed. We further used these indicators to evaluate and compare similarities and differences of policy features across countries using descriptive statistics and graphical approaches. Results: CDC programs in the Netherlands, Arkansas, and the UK ranked at the top in consumer direction. All countries except Germany employed a “service-based” principle in determination of service type. Training care workers was in the most widespread use to assure quality of care. Merely the UK and Germany integrated CDC and conventional agency care without restrictions. Representative with relevant support was only available in the UK and Netherlands. Discussion and Implication: CDC models involve multi-faced aspects, rather than dichotomies and discrete entities. Implications include the need for a systematic reflection with our developed framework and enriching variety of service options to promote consumer direction.

UNDERSTANDING GLOBAL DEPRESCRIBING POLICY: OPPORTUNITIES AND CHALLENGES

Catherine Kim,¹ Allison Thompson,² Grace Kim,² Zachary Marcum,³ Michelle Keller,⁴ Andrea Sorensen,⁵ and Nicole Brandt,² 1. *University of Maryland School of Pharmacy, BALTIMORE, Maryland, United States*, 2. *University of Maryland School of Pharmacy, University of Maryland School of Pharmacy, Maryland, United States*, 3. *University of Washington, Seattle, Washington, United States*, 4. *Cedars Sinai, Cedars Sinai, California, United States*, 5. *UCLA, UCLA, California, United States*

The landscape of deprescribing, the planned process of dose reduction or stoppage for medications which are no longer of benefit, has been rapidly expanding with global efforts and the formation of regional and national deprescribing networks. The purpose of this qualitative study is to describe successes and challenges about deprescribing from thought-leaders across the world to inform future policy initiatives. We aim to conduct at least 15 key informant (KI) interviews; we have completed 13 to date. Codes were constructed to identify themes that depict the perspectives regarding deprescribing policy across the globe. The KIs primarily represent the fields of pharmacy and medicine from four global regions with years of deprescribing experience ranging from 5 to > 20. We identified two emerging overarching themes through our qualitative analysis: Regional Organization Support and Evidence & Knowledge gaps. Within these overarching themes, we further identified sub-themes and their representative quotes: Network Structure: “idea of the network was threefold: 1) To try and figure out what we need to activate healthcare providers to deprescribe; 2) To do work with community-dwelling seniors to motivate them and give them opportunities to deprescribe; 3) ...getting pharmacists to provide the education to the patients.” Cost-effectiveness: “If we can show that it is cost-effective to deprescribe, that there is actually a return here, not just in health terms but in monetary terms, I think that would really push it along.” This research will help to advance global efforts to optimize medication management.

Session 9315 (Poster)

Grandparents Raising Grandchildren

ACCEPTANCE COMMITMENT THERAPY INTERVENTION FOR CUSTODIAL GRANDFAMILIES: A VIRTUAL IMPLEMENTATION

Ella Faulhaber,¹ Meghan Custis,² Emily Heupel,¹ and Jeongeun Lee,¹ 1. *Iowa State University, Ames, Iowa, United States*, 2. *Iowa State University, MUSCATINE, Iowa, United States*

Custodial grandfamilies often face challenges, such as psychological distress, parenting burden, and grandchildren showing internalizing and externalizing behaviors. Given their circumstances, effective training and education is critical to provide a supportive family environment for both custodial grandparents and custodial grandchildren. The aim of this study was to develop, pilot and evaluate a psychosocial intervention for custodial grandfamilies. The program, interACT, was implemented virtually due to restrictions related to COVID-19. It is an intervention for custodial grandparents (CGPs) and custodial grandchildren (CGC) to improve psychological wellbeing and life skills. Participant eligibility was determined by grandfamilies having Iowa residency and legal guardianship or custody of an 8-12 year old grandchild. The program utilizes the Acceptance and Commitment Therapy (ACT) framework, focusing on psychological flexibility, acceptance, and psychosocial resilience for CGPs and CGC. The program used techniques such as mindfulness, self-compassion, and decision-making skills. During the pilot program stage, participants were divided into CGPs and CGC groups, and completed self-paced weekly 45 minute long modules through a program website. To enhance online session experience, Extension staff facilitated hour-long Zoom calls to discuss module contents and foster peer connection for both groups. Findings will be available at the conclusion of the pilot program. We expect to find increased psychological well-being and improved life skills for both groups right after the implementation of the ACT. Findings and limitations will be discussed with practical implication for program implementation via virtual delivery for the current custodial families. Future studies could extend current curriculum to other populations.

GRANDPARENTS RAISING GRANDCHILDREN: APPLYING BIOECOLOGICAL THEORY TO SCHOOL RELATIONSHIPS AND GRANDPARENT NEEDS

Katharine Black,¹ and Nancy Mendoza,² 1. *The Ohio State University, Ottawa, Ohio, United States*, 2. *The Ohio State University, The Ohio State University, Ohio, United States*

This paper examines the development, sustainability and importance of positive working relationships between grandparents raising grandchildren (“grandparents”) and school district staff through the application of Bronfenbrenner’s bioecological theory of human development. Grandparents have unique needs and often lack adequate resources, knowledge, and support when engaging in their new and often sudden role as primary caregiver of a grandchild. Access to educational resources, adequate information, and school

district support is critical as a grandchild transitions into their grandparent’s home. This inquiry aims to develop a conceptual framework for understanding how forming and maintaining positive working relationships between grandparents and school district staff will systematically and adequately address the educational needs of grandparents and their grandchild’s academic success. Tenets of the bioecological model include the application of proximal processes that outline the need for frequent and regular interactions between a person and their environment over extended periods of time. The purpose of this study is to develop positive pathways of support through the application of the interconnected elements of proximal processes of the bioecological theory including process, person, context, and time, and the five bioecological interactive (micro-, meso-, exo-, macro-, chrono-) systems of human development. More specifically, educational needs of grandparents as caregivers are addressed through tenets of the bioecological theory to inform school districts and encourage the development of positive working relationships and effective education navigation protocols to better serve this unique and growing population.

IS AGE JUST A NUMBER? INFLUENCE OF CAREGIVER AGE ON INJURIES OF CHILDREN RAISED BY GRANDPARENTS

Acacia Lopez,¹ Rachel Scott,² and Danielle Nadorff,³ 1. *Mississippi State University, Starkville, Mississippi, United States*, 2. *Mississippi State University, Starkville, Mississippi, United States*, 3. *Mississippi State University, Mississippi State, Mississippi, United States*

Unintentional injuries are the most common cause of death for children in the United States. One factor linked to their occurrence is parenting style (i.e., a collection of factors such as physical health, mental health, and possible cohort differences in parenting role expectations). Differences in parenting behaviors may be evident in grandparents caring for their grandchildren, due to cohort differences and age-related declines in cognitive and physiological processes. This may impact their abilities to monitor, supervise, and respond to children. Further, Hayslip & Kaminski report custodial grandparents are less likely than parents to understand and respond to the psychological and emotional needs of children but are more likely to enforce discipline. This study sought to explore the ways in which parenting styles are associated with unintentional injury behaviors in children (via caregiver age) for grandchildren raised by grandparents. Participants were grandparents raising their grandchildren, recruited via Qualtrics Panel Service (N = 323). Conditional process analyses were conducted using Model 1 of SPSS PROCESSv3.5. Age moderated the relation between consistency of discipline and child unintentional injury (F (1, 231) = 12.67, p <.001) as well as level of supervision and child unintentional injury (F (1,146) = 6.23, p = .01). Age did not moderate the relation between positive parenting and unintentional injuries. These results imply that children being raised by older grandparents were especially at risk for increased injuries when their grandparents used less consistent discipline or lower rates of supervision. Pathways are suggested for age-specific psychoeducation interventions for custodial grandparents.

PREDICTORS OF CUSTODIAL GRANDPARENTS' PERCEIVED BARRIERS TO THE USE OF SERVICES

Julian Montoro-Rodriguez,¹ Bert Hayslip Jr,² and Jennifer Ramsey,³ 1. *UNC Charlotte, Charlotte, North Carolina, United States*, 2. *University of North Texas, Denton, Texas, United States*, 3. *Case Western Reserve University, Cleveland, Ohio, United States*

Getting timely access to help, information, and a variety of services is paramount among the challenges of raising a grandchild, and grandparents face a variety of internal and external barriers in getting such help. The present pilot exploratory study focused on caregiving-related and personal resource variables best predicting grandparent caregivers' perceptions of barriers to receiving services. Fifty-two grandparents (M age = 59.1) raising their grandchildren completed measures assessing caregiver strain, social support, resilience, self-care, psychosocial adequacy, health, depression, and grandchild relationship quality. They also completed measures of the extent to which they faced personal and caregiving-related difficulties giving rise to the need for services (e.g. health, grandchild well-being, support from others) as well as the extent to which they had experienced barriers to service (health/financial limitations, isolation, transportation, respite care, lack of knowledge of services) in the past 3 months. Correlations ($p < .05$) suggested that psychosocial adequacy ($r = -.32$), depression ($r = .27$), caregiver strain ($r = .42$) and difficulties ($r = .48$) were all related to greater perceived barriers. Regression analyses ($F(7, 40) = 2.81, p < .02$) indicated that caregiver strain (Beta = .33, $p < .05$) and difficulties giving rise to the need for services (Beta = .32, $p < .04$) emerged as most salient in predicting barriers. These findings underscore the fact that personal, caregiving-related, and interpersonal factors exacerbate the barriers associated with grandparents' accessing needed services and reinforce such factors' impact on grandparents as targets for overcoming impediments to accessing services among them.

SERVING KINSHIP FAMILIES DURING COVID: PIVOTAL MOMENTS

Andrea Smith,¹ Michelle Mongeluzzo,² and Tawyna Drente,² 1. *Western Michigan University, Ada, Michigan, United States*, 2. *Kids Central Inc, Wildwood, Florida, United States*

Kinship caregivers, who are relatives or non-family members providing care to children when biological parents are unable to do so, comprise over 2.5 million adults in the United States. The vast majority are grandparent caregivers. The 7.8 million children in their care make up approximately 10.5 percent of all children in the United States under the age of 18 (Generations United, 2017: State of Grandfamilies). Navigating daily life is often challenging. Kinship caregivers routinely face difficulties in multiple aspects of their lives, including finances, physical health, mental health, education, employment, parenting, and family relationships. The COVID pandemic heightened existing challenges and stimulated new issues for many kinship providers and the children in their care. This poster will highlight actions taken by one Family Service agency, annually serving approximately 225 kinship families, to meet the unprecedented needs of family members and kinship program staff during COVID.

A timeline of decision-related rationales, specific actions taken and results related to these actions will be presented. Data summarizing results for kinship families ($n = 32$) related to COVID-impacted programmatic responses and changes, including level of involvement with group services, recidivism, perceived isolation, and efficacy related to their caregiving roles will be presented. Results summarizing the impact of the agency's COVID-related responses on kinship staff ($n = 6$) will also be presented, including data on staff members' level of stress, perceived support, perceptions of programmatic effectiveness, and prioritized importance of changes will also be shared.

VIRTUAL EMPOWERMENT TRAINING: REACHING GRANDPARENT CAREGIVERS DURING COVID19

Carole Cox, *Fordham University, Fordham University, New York, United States*

COVID-19 has had a devastating impact on minority populations in the United States who have disproportionately been at risk of getting the virus, having severe illness, and dying from it, with these risks most pronounced for older adults. The impact has been particularly severe on the more than 2, 7 million grandparents raising their grandchildren in the United States. Covid-19 has added profound strains to these families as they struggle with resources and isolation, frequently without assistance as well as the challenge of helping children to navigate online learning. The Virtual Empowerment Training Project, developed as a 7 session pilot program for low income grandparent caregivers in New York includes classes that strengthen parenting, communication, coping with loss and grief, and community empowerment. Participants were given iPads and computer training prior to classes, all conducted through Zoom. Initial data from the 56 participants (M age = 62, Race/ethnicity=Black, 79%, Hispanic, 16%, Income annual 41% < \$15, K) indicate improvement, i.e. a lessening of Negative Affect regarding the grandchild ($p < .01$) in the quality of their relationships with their grandchildren while also experiencing a decline ($p < .01$) in their sense of parental efficacy, possibly reflecting their becoming more critical of their own parental skills. Participant evaluations of the course were overwhelmingly positive, with more than 90% finding it extremely helpful, valuable, and eager to share it with others and to become more involved in improving the lives of grandfamilies..

Session 9320 (Poster)

Health Care and Services

A CROSS SECTIONAL SURVEY OF FACTORS INFLUENCING HEALTHCARE ACCESS IN OLDER WOMEN OF SOUTH INDIA

Sreejith Sudhakar,¹ Justin Jose,² and Shanuga Cherayi,³ 1. *Manipal Academy of Higher Education, Manipal, Karnataka, India*, 2. *Dream A Dream, Cherupuzha, Kerala, India*, 3. *Dharmagiri jeevas Social Center, Cherupuzha, Kerala, India*

We examined the determinants of healthcare access barriers, treatment-seeking, and self-medication in older women

aged 60 years and more, using a cross-sectional survey design. Using a structured interview format, we interviewed 1005 older women from 7 out of 14 districts in the state through a stratified random sampling procedure. Multiple linear regression analysis results reveal that older women's healthcare access barriers significantly increased when they experienced a long duration of multimorbidity alongside poor recognition of autonomy and basic amenities available at health facilities. However, confidentiality, the ability to pay for healthcare expenditure, and the type of health care significantly improved healthcare access. In factors influencing older women's delay in treatment-seeking, optimal instrumental functionality in daily living, optimal quality of life and access to healthcare services significantly reduced delay in treatment initiation. Whereas poor health-seeking behaviors, long duration of multimorbidity, and the quality of basic amenities at hospitals significantly increased treatment initiation delay and explained 13.6% of the variance. In factors influencing older women's use of self-medication, advancing age, living in rural areas, optimal functionality, perception of providers' respect for confidentiality were associated with increased self-medication frequency. Whereas, better wealth status, prompt attention to older women's health needs, and basic amenities at hospitals significantly reduced their self-medication practice. Therefore, the optimal functional abilities, fewer morbidities, and optimal health system responsiveness significantly reduce healthcare access barriers and self-medication while improving older women's treatment-seeking behaviors.

A WINDOW TO TELEHEALTH GERIATRIC SOCIAL WORK JOB MARKET LANDSCAPE: A CROSS-SECTIONAL STUDY

Lihua Huang, *Grand Valley State University, Grand Rapids, Michigan, United States*

The purpose of this research study is to explore current Telehealth geriatric social work by describing its most recent job market characteristics. As part of a larger longitudinal research, data for this cross-sectional study was collected in January 2021. Three top job search engines, Google, ZipRecruiter, and Indeed, were used to collect data on Telehealth social work job openings. On each search engine, five searches were completed with the five key words: "social work" Telehealth jobs, LCSW Telehealth jobs, remote LCSW jobs, Telehealth "social work" jobs, and Telehealth "social worker" jobs. It analyzed 112 Telehealth geriatric social work job ads, 12.8% of total 873 ads from these fifteen searches. Results from descriptive and thematic data analysis show large, for-profit organizations are dominating the Telehealth geriatric social work field while small private practices are emerging during the pandemic. The study found Telehealth geriatric social work is providing vital continuum services to older people in communities, hospitals, and long-term care facilities at individual, family, and group levels. The results document innovative technological tools present new methods to engage, assess, and intervene, particularly with mental health needs. The Telehealth organizations are making the pitch to attract competitive professionals. While nearly 1/3 of the sampled organizations stated they intended to make Telehealth/remotely temporary, the study concludes Telehealth has built its infrastructure and

workforce to become an indispensable and ongoing part of gerontological and geriatric social work. Social work education, research, and practice must pay close attention to its implications in skill building.

CONTINUE OR NOT TO CONTINUE? ATTITUDES TOWARDS DEPRESCRIPTION AMONG COMMUNITY-DWELLING OLDER ADULTS IN CHINA

Jie Tan,¹ Li Zhang,² Ying Wang,¹ Lihui Chen,¹ and Chenkai Wu,¹ 1. *Duke Kunshan University, Kunshan, Jiangsu, China (People's Republic)*, 2. *Suzhou Municipal Hospital, Kunshan, Jiangsu, China (People's Republic)*

Inappropriate prescribing of medications and polypharmacy among older adults could lead to avoidable harms. It is hence vital to stop potentially inappropriate medications in this vulnerable group. An approach coined 'deprescribing' has been used to describe a patient-centered process of optimizing medication regimens. But patient resistance to discontinuing medication use is a significant barrier to deprescribing. The present study aims to describe attitudes towards deprescribing and to examine individual-based characteristics that might be associated with these attitudes among community-dwelling older adults in China. We conducted a cross-sectional study through in-person interviews using the validated Patients' Attitudes Towards Deprescribing questionnaire in two communities through the community-based physical examination platform. Participants were 65 years and older and had at least one chronic disease and one regular prescription medication. Of the 1,897 participants in the study, the average age was 74 years and 1,023 (53.9%) were women. The majority had one chronic disease (n=1,364 [71.9%]) and took 1-2 medications (n=1,483 [78.2%]). A total of 947 (50.0%) older adults reported being willing to stop taking one or more of their medicines if their physician said it was possible, and 1204 (63.5%) older adults wanted to stop a medicine been taking for a long time. Chronological age, marital status, number of chronic diseases, and self-rated health status were associated with the attitudes towards deprescribing. This study showed that half of the participants were willing to cease a medication that their physician though was no longer required. Individual-level factors were associated with attitudes towards deprescribing.

OLDER ADULTS' PERCEPTIONS AND USE OF PATIENT PORTALS: A COMPARATIVE ANALYSIS OF TWO SAMPLES

Hyojin Son,¹ Eun-Shim Nahm,² Shijun Zhu,² Elizabeth Galik,³ Barbara Van de Castle,² Kristin Seidl,² and Vince Russomanno,⁴ 1. *National Institutes of Health Clinical Center, Bethesda, Maryland, United States*, 2. *University of Maryland, Baltimore, Maryland, United States*, 3. *University of Maryland School of Nursing, Baltimore, Maryland, United States*, 4. *University of Maryland Medical System, Linthicum Heights, Maryland, United States*

Older adults can benefit from using patient portals. Little is known whether the perceptions and use of patient portals differ among diverse older adult populations. The aim of this study was to assess the difference in perceived usability of patient portals, self-efficacy for using patient

portals, and patient portal use between two adult samples aged 65 years or older. One sample was recruited from a health care system, including hospitals and clinics ($n = 174$), and the other sample was recruited from nationwide communities ($n = 126$). Conducting a secondary data analysis using two survey datasets, this study performed a series of linear and ordinal logistic regression analyses. The health care system sample had a higher mean number of chronic diseases and proportion of recent hospitalization than the community sample. The health care system sample showed higher perceived usability, self-efficacy, and usage frequency of patient portals compared to the community sample. eHealth literacy was a significant predictor of perceived usability and self-efficacy. Perceived usability was another significant predictor of self-efficacy. Self-efficacy and health condition variables significantly predicted the more frequent use of patient portals. Compared to the health care system sample, the relationship between perceived usability and use of patient portals was stronger and significant in the community sample. These findings suggest that approaches for promoting patient portal use should consider personal characteristics and health conditions of diverse older adult populations. Future research needs to focus on assessing the impact of using patient portals on older adults' health care outcomes.

PATTERNS OF HEALTHCARE COSTS AMONG OLDER ADULTS: DEMOGRAPHICS, HEALTH PERSONALITY, AND RESILIENCE

Rotem Arieli, and Peter Martin, *Iowa State University, Ames, Iowa, United States*

The purpose of this study was to examine healthcare costs of older adults in relation to demographic characteristics, individual health personality traits, and resilience. Data included 3,907 participants, 65 and older, collected by a large provider of Medicare Supplemental Health Insurance. The Health Personality Assessment*, Brief Resilience Scale, total healthcare cost, and demographic information were used. In our sample, the average healthcare cost was \$13,283.69 ($SD=30,784.87$), ranging from \$0–\$989,084, and higher healthcare costs were found among older, male, and less health-neurotic (i.e., lower health-related anxiety) adults. Configural frequency analyses were conducted to identify “types” and patterns of healthcare costs by age and gender. The following significant patterns emerged: Women in the oldest group with high healthcare costs and women in the young-old age group who had low healthcare costs occurred significantly more than expected by chance, $p < .01$. Next, we hypothesized configuration patterns for resilience, health personality, and healthcare costs. Results confirmed the following “types” or patterns occurring more often than expected by chance: less-resilient individuals with high health neuroticism and high healthcare costs, $p < .001$, and less-resilient, less-health-conscientious adults with high healthcare costs, $p < .001$. The results suggest higher healthcare costs for individuals who are less resilient, more neurotic about their health, and less disciplined in their health practices. Future intervention programs may benefit from promoting resilience, reducing health neuroticism, and increasing health conscientiousness. *The Health Personality Assessment (HPA) is © 2021 United HealthCare Services, Inc. All rights reserved.

PSYCHOLOGICAL INFLEXIBILITY AND GERIATRIC PRIMARY CARE: TRANSFORMING PERI-URBAN AND RURAL AGING

Lindsey Jacobs,¹ Rebecca Allen,² Timothy Ly,³ John Bell,⁴ Dana Carroll,⁵ and Anne Halli-Tierney,⁴ 1. *The University of Alabama, The University of Alabama, Alabama, United States*, 2. *University of Alabama, Tuscaloosa, Alabama, United States*, 3. *University of Alabama, University of Alabama, Alabama, United States*, 4. *The University of Alabama, Tuscaloosa, Alabama, United States*, 5. *Auburn University Harrison School of Pharmacy, Tuscaloosa, Alabama, United States*

Based on the acceptance and commitment therapy (ACT) framework, human suffering is thought to be caused by psychological inflexibility. Psychological inflexibility is characterized by rigid avoidance of unpleasant experiences, fusion with unhelpful thoughts, lack of contact with the present moment, fusion with a narrow self-narrative, and lack of clarity and contact with one's core values in life. Psychological inflexibility captures the unhelpful or unworkable ways in which individuals respond to emotional discomfort. Research using samples of adults under age 65 indicate that psychological inflexibility is associated with poorer quality of life and mental well-being; however, the literature on psychological inflexibility in older adults is limited. Patients ($N=129$) ages 65 and older presenting to a Geriatric Primary Care clinic in the Deep South completed measures of depression, anxiety, subjective health literacy, and psychological inflexibility. Our team used the Acceptance and Action Questionnaire-II (AAQ-II), which is the most commonly used measure of psychological inflexibility. Anxiety ($r = 0.66$, $p < .001$) and depression ($r = 0.70$, $p < .001$) were moderately correlated with psychological inflexibility, which is consistent with the existing literature on psychological inflexibility in adults under the age of 65. Subjective health literacy significantly predicted psychological inflexibility, $b = -.058$, $t(127) = -4.07$, $p < .001$. This finding provides additional support for the importance of increasing health literacy among older adults in the Deep South, as it has implications in level of psychological flexibility and, thus, quality of life and mental well-being.

SELF-REPORTED UTILIZATION OF NUTRITION-RELATED RESOURCES IN VETERANS COMPARED TO NON-VETERANS

Monica Serra,¹ Ronna Robbins,² and Odessa Addison,³ 1. *UT Health San Antonio - Barshop Institute, San Antonio, Texas, United States*, 2. *Audie Murphy VA Medical Center, San Antonio, Texas, United States*, 3. *University of Maryland School of Medicine, Baltimore, Maryland, United States*

As they age, Veterans are at elevated risk for developing nutrition-associated chronic diseases compared to their Non-Veteran counterparts. This is despite Veterans often being eligible for a variety of nutrition-related resources. This project compared self-reported utilization of community and government nutrition-related resources in male Veterans compared to Non-Veterans participating in the 2013-2014 and 2015-2016 National Health and Nutrition Examination Surveys. Veterans (mean: age: 59 years; BMI: 29 kg/m²; $N=135$) self-reported “yes” and Non-Veterans (age: 61 years; BMI: 30 kg/m²; $N=230$) self-reported “no to “ever having served on

active duty in the U.S. Armed Forces." A similar percentage of Veterans (3%) and Non-Veterans (4%) reported utilizing meal delivery programs (i.e., "Meals on Wheels) and eating at community or senior centers (both 7%) in the past year. Veterans were less likely than Non-Veterans to report receiving emergency food (i.e. from church or food bank) in the past year (7% vs. 12%; $P < 0.01$) and tended to be less likely to report ever having received benefits from a nutrition assistance program (NAP; i.e., Food Stamps) (27% vs. 32%; $P = 0.08$). Veteran also reported their household receiving more financial assistance the last time they received support from a NAP (\$281 vs. \$188; $P = 0.02$). These data suggest that Veterans have less reliance on NAP than Non-Veterans; however, when they do receive assistance, Veterans appear to receive greater financial support. Future studies are needed to identifying ways to improve access to nutrition-related resources in those at risk for food insecurity.

THE IMPACT OF A WHOLE HEALTH MODEL OF CARE ON PATIENT OUTCOMES

Anna Faul,¹ Pamela Yankeelov,² Joseph D'Ambrosio,² Sam Cotton,³ Barbara Gordon,¹ and Maria Hall-Faul,⁴
 1. *University of Louisville, Louisville, Kentucky, United States*, 2. *University of Louisville, University of Louisville, Kentucky, United States*, 3. *University of Louisville Trager Institute, University of Louisville Trager Institute, Louisville KY, Kentucky, United States*, 4. *University of Connecticut, University of Connecticut, Connecticut, United States*

The FlourishCare Model (FCM) transforms primary care sites by addressing all determinants of health and focusing on helping patients to flourish. The FlourishCare Index (FCI) is a clinical measure to assess the effectiveness of the FCM to address all determinants of health. We will present data on the effectiveness of the FCM serving 159 older adults with MCCs. The sample was mostly female (77%), White (64%), retired (54%), married (30%) or widowed (20%) and living in urban areas (64%). The mean age was 69 (SD=15), with 13 years education (SD=3). Patients changed significantly over time on total FCI scores (57%-72%; $\chi^2 = 3.80, SE = 0.63$). Results show significant growth over time for individual health behaviors (58%-67%; $\chi^2 = 2.14, SE = 0.84$), health care access (71%-89%; $\chi^2 = 4.43, SE = 1.00$) and social determinants (62%-85%; $\chi^2 = 5.54, SE = 1.02$) with psychological determinants (54%-61%; $\chi^2 = 1.74, SE = 0.95$) and environmental determinants (70%-81%; $\chi^2 = 2.81, SE = 1.62$) showing a trend to significance. Interaction effects with time show that the FCM supported patients with lower education attainment to improve at a higher rate than those with higher education attainment, for the total FCI score ($\chi^2 = -0.59, SE = 0.24$) and health care access ($\chi^2 = -0.94, SE = 0.38$). Receiving mental health counseling resulted in more improvement in psychological determinants than those who did not receive counseling ($\chi^2 = 3.43, SE = 2.04$). The FCM was able to support rural patients at a higher rate than urban patients to gain access to health care ($\chi^2 = 4.13, SE = 2.02$). The FCM supported Hispanic patients the most in improving social determinants of health ($\chi^2 = 8.40, SE = 3.93$). This study showed the importance of a systems approach to care using measures that focus on what matters most to older adults who value quality-of-life outcomes.

Session 9325 (Poster)

Health Care Utilization

EXPLORING DEMENTIA CARE IN AN ACUTE CARE SETTING: PERSPECTIVES OF SOCIAL WORKERS AND NURSES.

Ruth Dunkle,¹ Katherine Cavagnini,¹ Joonyoung Cho,¹ Laura Sutherland,² Helen Kales,³ Cathleen Connell,⁴ and Amanda Leggett,⁵
 1. *University of Michigan, Ann Arbor, Michigan, United States*, 2. *Wayne State University, Ann Arbor, Michigan, United States*, 3. *University of California, Davis, University of California, Davis, Sacramento, California, United States*, 4. *University of Michigan School of Public Health, Ann Arbor, Michigan, United States*, 5. *The University of Michigan, Ypsilanti, Michigan, United States*

Nurses and social workers in acute care settings have unique perspectives about providing care to persons living with dementia (PLwD) who experience behavioral and psychological symptoms of dementia (BPSD). Their distinctive roles and training have important implications for the recovery and well-being of PLwDs during hospital stays. This study utilized the "rigorous and accelerated data reduction" (RADaR) technique to compare perspectives of social workers (n=12) and nurses (n=5) in a Midwestern tertiary care facility about their caring for PLwDs with BPSD. Three major themes were identified: 1) patient engagement and coordination with family and professionals, 2) treatment and medical management, and 3) barriers to care. Similarities between social workers and nurses emerged within the themes, including the importance of family involvement and providing person centered care. Differences emerged particularly within the treatment and medical management theme, as nurses utilize medications to treat BPSD and social workers were more likely to use redirection. While there is distinctive training for nurses and social workers, both identified similar barriers to providing care to PLwDs with BPSD, including time constraints, competing demands, and lack of training on BPSD management. Results demonstrate how an understanding of the critical and complementary roles that nurses and social workers play in dementia care and work together to build a care team can inform best practices to support symptom management and quality of life in PLwDs. Continuing education and training could be beneficial for both professionals to improve the quality of care for PLwDs.

INSUFFICIENT SLEEP AND HEALTH CARE UTILIZATION: A SCOPING REVIEW

Kolade Olatunde,¹ and Susan Patton,²
 1. *University of Arkansas, University of Arkansas, Arkansas, United States*, 2. *University of Arkansas, Fayetteville, Arkansas, United States*

Insufficient sleep is a common problem among older adults with 26% over the age of 65 reporting less than seven hours sleep in a 24 hour time period. Evidence indicates that untreated sleep disorders are associated with osteoarthritis, heart disease, hypertension, diabetes, obesity, falls, decreased cognitive performance, and decreased health related quality of life in older adults. A scoping review was undertaken to determine what is known about the association between

insufficient sleep or insomnia and health care utilization. The Joanna Briggs Institute, Methodology for JBI Scoping Reviews was used to guide the review. Searches were conducted in PubMed, HINARI, Google Scholar and Cochrane databases. Twenty nine studies were included. Overall, the review indicates that reduced sleep is associated with a greater odds of difficulties in daily activities, higher rates of health care utilization and costs, and poly pharmacy. Findings also reveal sociodemographic and geographic variations in prevalence of healthy sleep duration. Although the majority of studies focused on the causes and consequences of insomnia and recommended clinical and behavioral health promotion interventions, there is a gap in studies related to the public health or economic impact of insufficient sleep. Research in this area will provide perspectives on the need to raise awareness of the importance of sleep and to incorporate the awareness into policies that improve sleep health.

OLDER NONMEDICAL AND MEDICAL CANNABIS USERS: HEALTH CHARACTERISTICS, CANNABIS USE PATTERNS, AND CANNABIS SOURCES

Namkee Choi,¹ and Diana DiNitto,² 1. *University of Texas, Austin, Texas, United States*, 2. *University of Texas at Austin, Austin, Texas, United States*

Despite rapidly growing number of older medical cannabis users, research on them is scant. In this study, we examined medical and nonmedical cannabis users aged 50+ on health-related characteristics and cannabis use patterns and sources. Hypotheses were that compared to nonmedical users, medical users are more likely to have physical and mental health problems, use healthcare services, discuss their drug use with a healthcare professional, use cannabis more frequently, and purchase cannabis from a medical dispensary and other sources rather than obtain it as a gift, share someone else's, or use other means. We used the 2018 and 2019 National Survey on Drug Use and Health data (N=17,685 aged 50+; male=8,030; female=9,655) and multivariable logistic regression analysis to test hypotheses. Of the sample, 8.9% reported past-year cannabis use. Of past-year users, 18.5% reported any medical use. Of medical users, 70.9% reported exclusive medical use and 29.1% reported using medically and nonmedically. A large proportion obtained cannabis from private/informal sources. Any medical use, compared to nonmedical use, was associated with lower odds of alcohol use disorder but higher odds of discussing drug use with a healthcare professional (AOR=4.18, 95% CI=2.53-6.89), more days of use (AOR=2.56, 95% CI=1.35-4.86 for 200-365 days), and purchase at a medical cannabis dispensary (AOR=4.38, 95% CI=2.47-7.76). Medical and nonmedical users did not differ on physical health, and both had high behavioral health problem rates. However, only a small portion discussed their drug use with a healthcare professional. More healthcare professional attention to older cannabis users is needed.

SOCIAL WORKERS IN PRIMARY CARE INCREASE ACCESS TO PALLIATIVE CARE

Portia Cornell,¹ Christopher Halladay,¹ Pedro Gozalo,² Anna-Rae Montano,¹ Caitlin Celardo,³ and James Rudolph,¹ 1. *Providence VA Medical Center, Providence, Rhode Island, United States*, 2. *Brown University, Providence, Rhode Island, United States*,

3. *Northport VA Medical Center, Northport VA Medical Center, New York, United States*

Clinical trials show that palliative care improves patient experiences and reduces costs, and use of palliative care and hospice care have been increasing over the past three decades. In the Veterans Administration health care system (VA), Veterans may receive palliative care concurrently with other treatments. However, many barriers exist to the use of palliative care, such as patients' misperceptions. Social workers in primary care teams may increase use of this valuable service by establishing trust between patient and care team, educating patients and caregivers, and coordinating services. Leveraging a national social-work-staffing program as a natural experiment, we evaluated the effect of hiring one or more social workers to the primary-care team on use of palliative or hospice care among Veterans with a recent hospital stay. Our data included 91,675 episodes of care between 2016 and 2018. 1.45 percent of episodes were followed by use of palliative care or hospice within 30 days. The addition of one or more social workers through the staffing program was associated with an increase of 0.53 percentage points ($p < 0.001$) in the probability of any palliative or hospice care, i.e., a more than 30% increase relative to the mean. Policy makers and health system leaders who seek to improve patient experience and reduce costs through increased access to palliative and hospice care could consider social work staffing as a policy tool to achieve those aims.

TALKING ABOUT COMPLIMENTARY AND ALTERNATIVE MEDICINE: A CONVERSATION ANALYSIS STUDY

Sean Halpin,¹ Kathleen Len,² and Michael Konomos,³ 1. *University of Georgia, Decatur, Georgia, United States*, 2. *University of California Los Angeles, University of California, Los Angeles, California, United States*, 3. *Emory University, Atlanta, Georgia, United States*

Multiple Myeloma (MM) is a clonal plasma cell malignancy characterized by low blood counts and increased risk of infection, and primarily afflicts older adults. Although MM is incurable, advances in treatment, including autologous stem cell transplant (ASCT) has improved the lifespan of patients. MM patients commonly use over-the-counter complementary and alternative medicines (CAM) alongside conventional cancer therapies which, often without recognition by health care practitioners, may impact their treatment. Using data from an 18-month ethnographic study, we applied conversation analysis to examine 1180 minutes of audio-recordings to describe how patients and nurses interacted about CAM during ASCT education visits. Patients (n=12) had a median age of 62 years (IQR= 54-73), were mostly white (n=12, 75%), male (n=9, 56%), and had a moderate score on the FACT-G7 of 15 (IQR= 10-20). All patients had a caregiver present during their visit. Nurses (n=3) were aged 39 (IQR= 29-49) all with at least five years providing care to patients with blood cancers. Results suggested that nurses rarely provided direct feedback about CAM modalities, instead providing brief responses, and moving on to other topics. Excerpts were categorized into three groups, (1) demonstration of implicit epistemic authority, (2) demonstration of deferred epistemic authority in patient-initiated conversations, and (3) demonstration of deferred epistemic

authority in nurse-initiated conversations. Understanding how conversations surrounding CAM are navigated can provide insights into patient-communication in general, and methods for improving ASCT education.

THE EFFECT OF HOME- AND COMMUNITY-BASED SERVICES ON ACTIVITY ENGAGEMENT

Peter Sun, *Washington University in St. Louis, St. Louis, Missouri, United States*

This study examined the association between home- and community-based services (HCBS) and social, cognitive, and physical engagement among community-dwelling older adults in the U.S. Data were drawn from the 2012 Health and Retirement Study (HRS). The sample consisted of respondents ages 50 and over who answered questions on HCBS utilization and activity engagement ($n = 567$). Genetic matching and propensity score weighting were used to mimic randomized control and treatment groups, in order to estimate the population average treatment effect on the treated (PATT). HCBS utilization was found to be significantly associated with social engagement (PATT = 0.17, SE = 0.05, $p < 0.05$) and physical (PATT = -0.20, SE = 0.07, $p < 0.05$) engagement but not significantly associated with cognitive engagement (PATT = -0.04, SE = 0.12, $p > 0.05$). Sensitivity analyses found that the results were robust to the estimation model. These findings suggest that HCBS utilization is a promising model for increased activity engagement, and future policies aimed at targeting these outcomes are warranted.

Session 9330 (Poster)

Health Promotion (AGHE Poster)

DEVELOPMENT OF DIET SCORE FOR REFLECTING DIET PATTERNS AND DIETARY GUIDELINES: A CASE OF SINGAPORE

Yuezhong Liu,¹ Rakhi Verma,² Ringo Ho,³ and Yin-Leng Theng,¹ 1. *Nanyang Technological University, Singapore, Singapore*, 2. *Nanyang Technological University, Singapore*, 3. *Nanyang Technological University, Singapore, Singapore, Singapore*

Foods and dietary patterns substantially affect health outcomes. The overall dietary assessment score associated with dietary guidelines in Singapore has not been assessed previously. This study aimed to develop and evaluate diet score for identifying the relationship between dietary patterns and dietary guidelines in Singapore. Using a localised diet score survey collaborated with the Commonwealth Scientific and Industrial Research Organisation (CSIRO), we conducted a cross-sectional study of 600 Singapore persons in two-generational cohorts (40-64: 300 and > 65 years: 300). The proposed local diet score was calculated to reflect their overall compliance with the Dietary Guidelines in Singapore. ANOVA analysis was used to identify the significant difference among socio-demographic variables associated with diet score and comparison analysis was performed to compare the diet patterns and diet score. There are significant differences among age, education, housing, residency associated with diet score. Diet score of older cohort ($M = 67.71$, $SD =$

13.38) is significantly higher than young cohort ($M = 60.73$, $SD = 14.71$). The highest education level (University or tertiary) obtain the lowest diet score ($M = 58.58$, $SD = 14.41$). The participants who live in the landed property ($M = 69.45$, $SD = 14.43$) are higher than those who live in Condominium and Public House. And the participants who live alone ($M = 67.26$, $SD = 14.66$) have a higher average diet score. Two-generational cohorts are not compliant with recommendations about dietary guideline well in Singapore. The present findings suggest that dietary patterns need improvement in aspects such as vegetables and extra food components.

FOOD INSECURITY IN OLDER ADULTS: GERONTOLOGY STUDENTS AND RSVP A PARTNERSHIP THAT WORKS

Phyllis Greenberg,¹ and Jessica VanderWerf,² 1. *Saint Cloud State University, St. Cloud, Minnesota, United States*, 2. *St. Cloud State University, Saint Cloud State University, Minnesota, United States*

A gerontology course related to policies /programs each year researches, develops and designs a service-learning project related to an issue/concern for older adults and their quality of life. Students wanted to work with vulnerable older adults and after research and discussion decided on tackling the issue of food insecurity in older adults. Food insecurity is a growing issue for older adults which has been exasperated by COVID-19. According to Meals on Wheels America (2020) there has been a 22% increase in the number of older adults needing food assistance. In addition, while the need for food banks has increased donations have declined (Next Avenue, 2020). Students partnered with RSVP, which had previously conducted a food donation project.. Students took on the responsibility for advertising, soliciting grocery stores to allow us to set up and engage shoppers in purchasing items for the project. In addition, they reached out to the university community and set up food donation stations. RSVP sent out emails to their constituents to encourage them to volunteer and do their shopping on the date of the project. Students were paired with RSVP volunteers at two stores and provided shopping lists and information about food insecurity in older adults to shoppers. Students collected 566 pounds of food. The food was distributed equally between Catholic Charities, which has a senior shopping program and the Somali Elder Community. Students sorted the food by categories and removed any foods with pork/gelatin products for the Somali Community.

GERIATRIC ORAL HEALTH FOR DENTAL AND NON-DENTAL PRIMARY CARE PROVIDERS

Maryam Tabrizi, *The University of Texas School of Dentistry at Houston, Houston, Texas, United States*

Age-Friendly Health System is the innovation that provides care to older adults within 4Ms structure comprehensively. The 4Ms structure is the clinicians' guideline for providing treatments for each individual based on what matters most which is the first M. The 4Ms structure creates a person focus approach for the health of the elderly on every visit, as what matters most may change over time based on other health conditions of life situation. We must consider our patients come from all kinds of life walks, based on his/ her lifestyle, health beliefs, and cultural background. Consequently, older adults may

define health and wellness differently and they might have different needs, oral health is no exception. However, evaluating both primary care office workflow and hospital workflow is missing the health element of oral care. The current health flow designed by the Institute of Health Improvement (IHI) in a collaborative effort with John A. Hartford may create a larger gap between oral health and overall health. In the light of integrating oral health to the overall health, the best place and most feasible in both primary care and hospital workflow is at the time of Check history for a baseline on 4Ms. This poster will clearly illustrate how oral health can integrate to overall health leading by the non-dental profession who usually take history for a baseline. As oral health is an integrated factor in the health of the geriatric population in the Age-Friendly Health System.

GLOBAL UNBIASED DETERMINATION OF COMORBIDITY (GUDC) IN U.S. OLDER ADULTS

Beth Hogans,¹ Bernadette Siaton,² Raya Kheirbek,³ Leslie Katzel,¹ and John Sorokin,⁴ 1. VAMHCS, Baltimore, Maryland, United States, 2. University of Maryland School of Medicine, Baltimore, Maryland, United States, 3. University of Maryland School of Medicine, University of Maryland School of Medicine, Maryland, United States, 4. University of Maryland, Baltimore VA Medical Center, Maryland, United States

With age, many adults develop multiple comorbid conditions; and resulting clinical complexity increases markedly so that identifying how specific conditions effect others remains important. Here, our primary objective was rapid unbiased appraisal of pair-wise condition-specific comorbidity; our second objective was identification of common conditions with highest and lowest rates of such comorbidity. In 2016, utilization of ICD-10 codes became mandatory for providers rendering care to Medicare beneficiaries. Universal adoption of ICD-10 coding ensued and concomitantly, all patients had ICD-9 codes replaced with new codes, so that 2017 data represent an opportunity to examine massive amounts of ‘freshly’ coded patient claims data. Evaluating ICD-10 coding data at individual and population levels, we appraised how often two codes were utilized together, i.e. estimated pair-specific comorbidity. Expanding this computationally, we determined the extent to which any given condition was co-coded with all other utilized diagnostic codes, i.e., estimated global, unbiased pair-wise comorbidity. We term this metric the global unbiased dyadic comorbidity (GUDC) value. Based on 40 million claims for a representative sample of 1.5 million older adults across the U.S., GUDC values varied with age and gender but were highly stable across varying comorbid condition prevalence, e.g., common (>1%) vs. less common (1/1000-1/100) prevalence. GUDC values for HIV in older adults were modest, compared to high values for ARDS, we infer substantive progress in HIV management among older adults. We discuss the interpretation and potential applications of GUDC and conclude that access to comorbidity appraisals may advance geriatric care, more study is needed.

PAEAN: PAIN IN AGING, EDUCATIONAL ASSESSMENT OF NEED - AN INTERPROFESSIONAL COLLABORATION

Beth Hogans,¹ Bernadette Siaton,² Laura Frey-Law,³ Lana Brown,⁴ Chris Herndon,⁵ Luis Buenaver,⁶ Les Katzel,²

and Patricia Thomas,⁷ 1. VAMHCS, Baltimore, Maryland, United States, 2. University of Maryland School of Medicine, Baltimore, Maryland, United States, 3. University of Iowa Health Care, Carver College of Medicine, Iowa City, Iowa, United States, 4. Central Arkansas Veterans Healthcare System, Little Rock, Arkansas, United States, 5. School of Pharmacy Southern Illinois University Edwardsville, Edwardsville, Illinois, United States, 6. Johns Hopkins University, Baltimore, Maryland, United States, 7. Case Western Reserve School of Medicine, Cleveland, Ohio, United States

Pain is prevalent in older adults limiting independence directly and through comorbidity-related effects on functional domains such as mobility, well-being, sleep, productivity, and oligo-pharmacy. Improved outcomes for older adults with pain depends on provider knowledge and competence; concomitantly, Veterans, women, and others at socioeconomic disadvantage may face increased pain, comorbidities, and complications of treatments. Previous guidance for educational programs, from pre-licensure to post-graduate training, in geriatrics and pain have focused on expert opinion, whereas an evidence-based approach is preferred. Our working group is conducting a structured needs assessment regarding comorbidities of common pain-associated conditions in older adults. Methods: To capture expertise in medicine, nursing, pharmacy, clinical psychology, and physical therapy, we extended an open invitation to members of the VA Geriatric Research, Education, Clinical Centers Associate Director-Education network and selected, nationally-recognized clinical education experts outside VA. Results: An eight-member working group, interprofessional in composition, through multiple remote meetings has defined goals of the program, evaluated preliminary evidence addressing the clinical needs of older adults with pain, and posed ‘curious questions’ about the available large-scale data. The overarching goal is evidence-based needs assessment of gaps in education about pain in older adults, with purposeful attention to risks of healthcare inequities for older adult women, Veterans, persons of color, those at socioeconomic disadvantage, and caregivers. Conclusions: Interprofessional collaboration is effective in framing a broad needs assessment regarding pain and common comorbidities in older adults with the intent of meeting the educational needs of clinical trainees. More study is needed.

SAVING SENIOR SMILES: A COMMUNITY OUTREACH EDUCATIONAL PROGRAM AND PILOT RESEARCH PROJECT

Prajakta Joshi,¹ and Kadambari Rawal,² 1. Boston University Henry M. Goldman School of Dental Medicine, Boston, Massachusetts, United States, 2. BU Henry M Goldman School of Den, Boston university, Massachusetts, United States

Globally, poor oral health has been evidenced more frequently among older adults. Thus, it is imperative to develop strategies for improving the oral health knowledge and access to dental care amongst the older adult population. The Saving Senior Smiles (S3) pilot outreach program was launched as an oral health education and awareness program for community-dwelling older adults across senior centers in the greater Boston area (Massachusetts, USA). The outreach consisted of oral health educational seminars presented by

pre-doctoral dental students from three dental schools in the Boston area. The presentations highlighted the significance of oral health, and the importance of seeking routine dental care. Pre and post-test surveys were administered to assess the participants' utilization of oral health services and oral health knowledge. The surveys were completed by 85 older adults (Female= 58.8%) across five senior centers. Questions pertaining to utilization of dental services revealed that 78.8% of the participants had a dentist. Expectedly, the center that reported the greatest number of missing teeth (Fenway center= 70.6%) had the least number of individuals who had a dentist (58.3%). With regard to oral health knowledge, before the seminars, less than half of the participants (42.2%) across all the senior centers were aware of the common oral conditions that affected older adults (dry mouth, gum recession and changes in oral bacteria) and after the presentation over 60% of the participants responded correctly to these knowledge questions. Overall, these findings emphasize the value of simple community-based interventions for older adults.

Intervention Research

Session 9335 (Poster)

COMPUTER-MEDIATED FOCUS GROUPS TO ADVANCE AGING RESEARCH: CHALLENGES AND OPPORTUNITIES.

DAVID Coon, Abigail Gomez-Morales, phil Carll, Lourdes Cordova, allison Glinka, and Socorro Gonzalez-Piles, *Arizona State University, Phoenix, Arizona, United States*

When compared to in-person offerings, fewer focus groups to date have been conducted with user-friendly technologies to help reach diverse communities of older adults with chronic health conditions (e.g., Alzheimer's disease, Type II diabetes, Parkinson's) and the family caregivers and professional providers who assist them. The current project describes the adaptations needed to deliver successful computer-mediated focus groups via videoconference, thereby providing solutions to barriers faced by participants who often cannot attend in-person because they are housebound due to transportation or financial barriers, live in rural areas or reside too far from focus group offerings, or work full or part-time and face scheduling conflicts. During the pandemic, we successfully recruited diverse groups of family caregivers, care recipients, and professional providers into computer-mediated focus groups. Caregivers (83%) and care recipients (17%) between 34 to 90 years old (N=47) took part in the series of focus groups facilitated in English and Spanish (25.5%). Over 40% of participants self-identified as Hispanic or Latinx, Native American, or African American with roughly 15% attending from rural areas. Similarly, professional providers age 18 to 80 (N=25) attended separate groups in either English or Spanish (48%). Our results suggest that computer-mediated focus groups offer a unique opportunity to reach diverse samples of older adults, family caregivers, and their providers. These computer-mediated focus groups also offer the chance to learn novel ways to break barriers to health access by providing virtual reach

capabilities for those facing health, transportation, work, or geographic barriers.

DEVELOPMENT OF ONLINE CHILD SUPPORT ACTIVITIES BY OLDER ADULTS; AN ACTION RESEARCH DURING THE COVID-19 PANDEMIC

Mai Takase,¹ Ryogo Ogino,² Ryoichi Nitani,³ and Jun Goto,⁴ *1. The University of Tokyo, Bunkyo-ku, Tokyo, Tokyo, Japan, 2. Saga University, Saga, Saga, Japan, 3. the University of Tokyo, Tokyo, Tokyo, Japan, 4. Tokai University, Hiratsuka, Kanagawa, Japan*

Japanese communities have been attempting a novel type of childcare support, wherein community-dwelling older adults form a specialized group (support group) that aims to provide child support activities. Before the COVID-19 pandemic, the group gathered children and mothers in community spaces and conducted events. However, on-site support had to be halted due to the pandemic. In this study, we report a case of action research aimed at shifting the activities online. First, a suitable online support plan was explored by hosting several discussions with child-rearing mothers. A questionnaire survey was then conducted to determine the most-sought intervention contents (N=19). Finally, based on the results, an intervention was conducted. As a result of the discussions, the hosting of online programs was set as the main goal. Out of the ten activities studied, the three most popular activities were programming (n=17), English conversation (n=16), and science workshop (n=15). Based on the results, an online science workshop that built a Bottleium, a small aquarium using a bottle, was hosted. Eight children participated in the event. A post-activity survey revealed that all participants attended the online activity for the first time, and the parents were happy to have joined the activity that entertained their child during the quarantine period. Furthermore, focus group interviews were conducted with the support group; they reported being satisfied with the outcome and recognized the importance of their role as member of support group. The results suggest the positive effect of this project on both older adults and the children.

EFFECTS OF A 6-WEEK INTEGRATED DEMENTIA PREVENTION INTERVENTION IN COMMUNITY-DWELLING OLDER ADULTS

Sunghee Tak,¹ Ji-yeon Kim,² Hana Ko,³ SuJung Jung,⁴ and Jaegyeong Lee,¹ *1. Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Eulji University, Uijeongbu, Seoul-t'ukpyolsi, Republic of Korea, 3. Gachon University, Incheon, Seoul-t'ukpyolsi, Republic of Korea, 4. Semyung University, Jecheon, Seoul-t'ukpyolsi, Republic of Korea*

This study examined the week of a 6-session integrated dementia p program on dementia knowledge, attitude toward dementia, fear of dementia, and dementia prevention behaviors among community dwelling elders. Using a nonequivalent control group, pre-posttest design, study participants were recruited from a senior center in Seoul, Korea. A total of 40 participants completed the study while half of them were in the experimental group and another half were in the control group. They completed survey questionnaires before and after the program. The findings showed that the

program was effective only to decrease the fear of dementia of the older adults. Knowledge, attitude toward dementia, and healthy behaviors may be difficult to change in a short period of time. However, the integrated dementia prevention program may be effective to decrease negative emotions, particularly, fear toward dementia among older adults. The fear of dementia needs to be further assessed individually in order to identify particular causes and triggers and provide tailored interventions.

EXPLORING FACTORS THAT SHAPE ADHERENCE TO TECHNOLOGY-BASED COGNITIVE INTERVENTIONS

Erin Harrell,¹ Nelson Roque,² Walter Boot,³ and Neil Charness,³ 1. *University of Alabama, Tuscaloosa, Tuscaloosa, Alabama, United States*, 2. *University of Central Florida, University of Central Florida, Florida, United States*, 3. *Florida State University, Tallahassee, Florida, United States*

A cognitive intervention study was conducted to explore methods to improve adherence to a technology-based cognitive intervention and uncover individual differences that predict adherence (N = 120). The study was divided into two phases: (1) in which participants were asked to follow a prescribed schedule of training that involved gamified neuropsychological tasks administered via a tablet, and (2), in which participants were asked to play as frequently as they wished. Positively and negatively framed messages about cognitive health were delivered via the software program, and measures of cognition, technology proficiency, self-efficacy, technology attitudes, and belief in the benefits of cognitive training were collected. We computed an aggregate measure of adherence during each of the two phases, as well as a measure of daily engagement. Across data modeling approaches, the finding was consistent: only during Phase 2, was there evidence that positively-framed messages encouraged greater adherence over negatively-framed messages. Measures of memory and self-efficacy demonstrated some, but limited, ability to predict individual differences in adherence.

FEASIBILITY AND BARRIERS OF AN OLFACTORY TRAINING INTERVENTION

Tomiko Yoneda,¹ Natalia López-Bago Cid,¹ Nathan Lewis,¹ Michael Willden,¹ Anna Nelson,¹ Nadia Semenoff,² Andrea Piccinin,¹ and Jamie Knight,¹ 1. *University of Victoria, Victoria, British Columbia, Canada*, 2. *University of Calgary, Calgary, Alberta, Canada*

Olfactory dysfunction is a common issue in late-life and can be an early indicator for neurodegenerative diseases. Further, olfactory interventions not only improve olfaction but have shown promise for the delay and treatment of dementia. This study aimed to better understand the feasibility and barriers of implementing an olfactory intervention. Participants (N=23) between the ages of 52-86 (mean=71) years were recruited from the community. A demographic questionnaire showed participants were all non-smokers and identified as women (70%), men (26%), and transgender (4%). The majority were married (61%), while some were separated or divorced (17%), widowed (13%), or single (9%). Four focus groups, guided by both structured and open-ended questions, were conducted and audio-recorded with 3-7 unique participants per group. Data were

transcribed, thematically analyzed, and independently coded, which resulted in three overarching themes: (1) cognitive, genetic, and environmental factors of smell, (2) methods to reduce barriers and increase the feasibility of an intervention, and (3) flexibility with technology use. Findings suggest that implementing an olfactory intervention is feasible and of interest to older populations especially when provided with detailed training protocols that have flexibility in the amount of technology used within the study. Barriers included sensitivity to smells, allergies, and dexterity issues. Reducing these barriers will facilitate implementation and decrease the likelihood of attrition. Consulting the target population provides insights into barriers, participant interest, and can assist with the development of training and intervention programs.

RESEARCH WITH OLDER ASIAN AMERICAN FAMILY CAREGIVERS PRE- AND DURING THE PANDEMIC: CHALLENGES AND LESSONS LEARNED

Jung-Ah Lee,¹ and Hannah Nguyen,² 1. *University of California, Irvine, Irvine, California, United States*, 2. *California State University, Dominguez Hills, Carson, California, United States*

Research with hard-to-reach, monolingual adults from ethnic minority communities can present a multitude of challenges throughout the research process. This presentation will highlight challenges and lessons learned from two pilot studies with Vietnamese-, Cambodian-, and Korean-American family caregivers aged 50 and older. The first study (n=9) implemented a one-on-one, telephone-based psychosocial intervention before the COVID-19 pandemic; the second is an ongoing study (n=12) consisting of a group-based intervention via Zoom. Throughout recruitment, the following challenges arose: addressing the lack of familiarity with research among caregivers, earning the trust of caregivers, and identifying creative ways to recruit caregivers to participate. During study implementation, common challenges included: caregivers' unpredictable daily schedule that made it difficult to participate in the scheduled classes, caregivers feeling apprehensive about technology and Zoom, access to reliable internet, and facilitating participation and engaging the voices of caregivers over the phone or via Zoom. Strategies were identified to address these barriers: engaging the support and collaboration of trusted, bilingual and bicultural community-based providers, building culturally-responsive rapport with caregivers, and seeking continuous feedback from caregivers to improve the appeal of the project implementation. The COVID-19 pandemic added an additional layer of difficulty to the research, requiring creativity and flexibility in implementation that took into consideration caregivers' heightened anxiety, distress, lack of participation due to around-the-clock care, and loss and grief. The challenges and lessons learned from these studies could guide the development of future research efforts and strategies to effectively engage older hard-to-reach, monolingual Asian American caregivers.

THE FOCUS GROUP MUST GO ON: LESSONS LEARNED FROM CONDUCTING VIRTUAL FOCUS GROUPS

Ashlee Cordell,¹ Christa Wilk,² Silvia Orsulic-Jeras,¹ Sara Powers,¹ Farida Ejaz,¹ and Lisbeth Sanders,³ 1. *Benjamin Rose Institute on Aging, Cleveland, Ohio*,

United States, 2. Benjamin Rose Institute, Cleveland, Ohio, United States, 3. LifeBio, Marysville, Ohio, United States

The Covid-19 pandemic has presented a multitude of challenges in conducting research with human subjects. In response, researchers have found creative ways to complete these studies using alternative methods that incorporate social distancing. Fortunately, numerous technologies exist today that allow individuals to connect with one another over short and long distances. The current study describes the development of LifeBio Memory: an app-based product that utilizes artificial intelligence and machine learning to improve an existing life story intervention designed for persons living with dementia (PWD). Seven focus groups (n=35), originally planned in-person, were successfully converted to a virtual setting. Groups were hosted using a Zoom platform, lasted 75-90 minutes (Mean = 85; SD = 5.3), and consisted of participants from 14 different states: One group of community-dwelling PWDs with early-stage dementia (n=5); two groups of current and former users of the original LifeBio program (n=12); and four groups of residential care staff and directors (n=18). Virtual focus group delivery was determined to be an acceptable and feasible alternative to traditional in-person formats. Topics discussed in this poster will include: 1) recruitment procedures, 2) screening protocols, 3) methods for sharing materials, 4) guidance for providing technology support, and 5) communication strategies to increase retention. Further discussion will focus on challenges faced when collecting data in a virtual setting, tips for successful facilitation, advantages to using virtual alternatives, and other lessons learned from the virtual field.

USING LIFE STORY TECHNIQUES WITH DIVERSE COMMUNITIES: LESSONS LEARNED FROM A FOCUS GROUP STUDY

Christa Wilk,¹ Ashlee Cordell,² Silvia Orsulic-Jeras,² Sara Powers,² Farida Ejaz,² and Lisbeth Sanders,³ 1. Benjamin Rose Institute, Cleveland, Ohio, United States, 2. Benjamin Rose Institute on Aging, Cleveland, Ohio, United States, 3. LifeBio, Marysville, Ohio, United States

Providing high quality, cost-effective dementia care remains a major health challenge. Life story work, used in residential care settings, helps engage persons living with dementia (PWD) at a low cost with minimal staff burden. LifeBio, one such intervention, is designed to elicit life history data and care preference information through comprehensive life story interviews. LifeBio Memory, an adaptation of LifeBio, utilizes novel speech-to-text technology to process life story data more efficiently. Seven focus groups were conducted to evaluate the acceptability and feasibility of LifeBio Memory. Three types of focus groups were held (n=35) and audio recorded: 1) One group of early-stage PWDs (n=5); 2) Two groups of current and former users of original LifeBio (n = 12); and 3) Four groups of residential care staff and directors (n=18). Sessions were transcribed and thematic analyses were conducted. Findings indicated high levels of acceptability and feasibility of LifeBio Memory. Further, a secondary theme emerged signaling the need to prioritize the emotional safety of PWDs participating in life story work. This poster will discuss: 1) the life story interview process, 2) identifying PWDs who would most benefit from a life story program, 3) involving family and staff care partners

to identify sensitive topics, 4) interview question design, selection and order, and 5) expanding life story work across diverse communities. Discussion will highlight the importance of protecting the emotional well-being of marginalized communities by identifying potential underlying traumas that could impact the safe delivery of otherwise effective life story interventions.

WHERE ARE ALL THE MEN? A REVIEW OF THE BARRIERS AND FACILITATORS TO PARTICIPATION IN HEALTH PROMOTION INTERVENTIONS

Britteny Howell,¹ Sage Corbett,¹ and Jennifer Peterson,² 1. University of Alaska Anchorage, Anchorage, Alaska, United States, 2. University of Alaska Fairbanks, Fairbanks, Alaska, United States

Research shows that men in the U.S. experience significant morbidity and earlier mortality than women and are less likely to access, interpret, and apply health information to improve their outcomes. Although evidence-based health promotion programs have proven successful at increasing healthy lifestyle behaviors and reducing morbidity among older adults, older males are still significantly less likely to enroll and sustain participation in such health interventions. While studies have shown the barriers and facilitators to older adult participation in health programs in general, it is largely unknown why older male recruitment and participation in health promotion interventions remains so low. In this poster presentation, we conducted a thorough review of the last 20 years of existing research across a variety of academic search databases to outline the barriers, facilitators, and recommendations for increasing older male participation in health promotion programs. Of 1,194 initial search results, 383 article abstracts were thoroughly screened for inclusion, and 26 articles met all inclusion criteria. Included studies were coded and analyzed using Grounded Theory and reveal that masculine gender roles, as well as program scope, environment, and gender of the instructors and other participants, were important factors for male participation. Interventions should include men in all aspects of program planning and implementation, take into account men's existing relationships and interests to create gender-sensitive programming, and clearly delineate the benefits to participation. Lastly, the field of public health would benefit by helping to normalize men's participation in health promotion interventions.

Session 9340 (Poster)

Life Course and Developmental Change

AGE, PERIOD, AND COHORT EFFECTS ON LITERACY SKILLS ACROSS LIFE STAGES

Takashi Yamashita,¹ Thomas Smith,² and Phyllis Cummins,³ 1. University of Maryland, Baltimore County, Baltimore, Maryland, United States, 2. Northern Illinois University, DeKalb, Illinois, United States, 3. Miami University, Oxford, Ohio, United States

Literacy skills are essential adult competencies for economic, social, political and cultural participation, which are linked to higher quality of life. Literacy skills are known to be lower for older age groups. However, relatively little is

known about cohort and period effects, which provide clues to the sociohistorical impacts on literacy, in addition to the well-known age effects, over the life course. This study analyzed three nationally representative cross-sectional survey data of the U.S. adults at five time points, from the 1994 International Adult Literacy Survey (IALS), 2003 Adult Literacy and Life Skills Survey (ALL), and the 2012/2014/2017 Program for International Assessment of Adult Competencies (PIAAC). The total analytic sample was 17,450 adults age between 18 and 65 years old. The literacy measures were re-scaled (0-500 points) to be comparable across the surveys. An age-period-cohort hierarchical linear model (i.e., cross-classified random effects model) was constructed using the Bayes estimator. Individuals were cross-classified based on 14 five-year birth cohort and 5 periods (survey years) information. Results showed that literacy skills improved [95% credibility-interval (CI) for linear effect of age = (0.31, 1.07), but the rate of improvement declined over time, faster rates of decline in later life stages [95% CI for quadratic effect of age = (-0.17, -0.09)]. Additionally, the notable variability across the cohorts and periods [95% CI variances = (5.34, 52.52) and (2.30, 172.01), respectively] were identified. Possible explanations for the identified age, period and cohort effects on literacy and implications for adult competencies in later life are evaluated.

DAILY STEPS BUFFER THE IMPACT OF DAILY STRESS ON MOOD IN YOUTH AND MIDDLE-AGED/OLDER ADULTS

Daniel Fleming,¹ Yin Liu,¹ Myles Maxey,² Elizabeth Braungart Fauth,¹ and Troy Beckert,² 1. *Utah State University, Logan, Utah, United States*, 2. *Utah State University, Utah State University, Utah, United States*

Physical activity has known associations with lower stress and improved well-being. These studies often include samples from one developmental phase at a time, which is helpful for researchers in those developmental areas, but less informative for identifying predictors of health and well-being across the lifespan. The current study examined whether protective aspects of physical activity (steps) on stress and mood worked similarly in widely different age cohorts. We also examined these relationships at the daily level, as opposed to global/macro levels. Participants (n = 119, 67% female) were 44 adolescents between 13-18 years (Mage (SD) = 15.73 (1.48) years, 57% female) and 77 middle-aged/older adults between 55-76 years (Mage (4.97) = 59.67, 74% female). They self-reported global life satisfaction and demographic characteristics at baseline and completed ecological momentary assessments (three per day for three consecutive days, across six measurement bursts, each spaced two weeks apart) via smart phones, reporting on their mood, stressor exposures/types, and end-of-day pedometer step count. Multilevel models showed that daily steps had protective effects against social network stressors on both daily mood and life satisfaction, such that more steps weakened the negative relationship between network-related stressors, mood, and life satisfaction. This protective effect was uniform for both older and younger adults, and across boys/men and girls/women. Overall, the present study suggested the importance of physical activity, even that of general step count, on buffering daily stress on daily mood and general life satisfaction for participants at multiple phases of the lifespan.

DEPENDENCY, MORTALITY, INVISIBILITY: LINKING CHILDHOOD DISABILITY WITH LIFE COURSE HEALTH OUTCOMES

Jessica Hoyle, James Laditka, and Sarah Laditka, *University of North Carolina at Charlotte, Charlotte, North Carolina, United States*

People who experienced disability in childhood are living longer. It is not clear if longer lives indicate better health and less dependency, or if longer life is accompanied by increased dependency. We addressed that question by studying the joint dynamics of mortality and dependency. This population is “invisible” in most national surveys, which do not ask about childhood disability. We evaluated special education history as an indicator of childhood disability, and used that indicator to estimate dependency and life expectancy throughout adult life. Data: Panel Study of Income Dynamics and the Health and Retirement Study (n=20,563). Activities of daily living (ADLs), instrumental ADLs, and cognition defined five functioning levels including dependency and death. Multinomial logistic Markov models estimated probabilities for transitioning among the levels, with or without a history of childhood disability, adjusted for demographics. We used the probabilities in microsimulations, creating large populations of completed lives, identifying dependency at each age for each individual. Analysis showed special education history was a valid indicator of childhood disability; 13% had such history. With parent education less than high school, remaining life at age 20 was 46.0 years for people with that history, 58.3 for others; corresponding results with parent’s bachelor’s degree: 48.3 and 60.7 (p < 0.05). Corresponding population percentages dependent 5+ years were: 15.2% and 3.8%, 13.1% and 3.8% (all p<0.05). Special education history can indicate childhood disability. People with that history had significantly more dependency than others, and shorter lives. Accommodations and interventions can improve their health and functioning.

DISCREPANCIES IN OBJECTIVE AND SUBJECTIVE FINE MOTOR ABILITIES IN OCTOGENARIANS

Elizabeth Braungart Fauth,¹ Andrew Hooyman,² Sydney Schaefer,² Anna Hall,¹ and Marie Ernsth-Bravell,³ 1. *Utah State University, Logan, Utah, United States*, 2. *Arizona State University, Tempe, Arizona, United States*, 3. *Jönköping University, Jönköping, Jonkopings Lan, Sweden*

Older individuals may have discrepancies between self-reported and performance-based abilities on activities of daily living (ADL). We examined objective and self-reported fine motor abilities (FMA). FMA are required for many ADLs, but are examined less frequently than gross-motor tasks in this population. We used two waves of the population-based OCTO-Twin study including mono-/dizygotic Swedish twins, aged 80+. One twin was randomly selected for analyses (baseline N=262; wave 2 N=198; Meanage =83.27; SDage=2.90; 66.4% female). Participants self-reported their ability to manipulate things with hands (cannot do, some problem, no problem) and completed a timed FMA assessment including five everyday tasks (e.g. inserting a key in a lock). Slow performance was coded as 1+ SD from the mean (=80+ seconds). At baseline, 65.8% of slow performers reported ‘no problems’ with hand manipulation. Over two waves (two years), a two-factor ANOVA (including slowness-by-perception interaction) supported a significant difference in total motor

task performance between slow performers reporting 'no problems' and fast performers reporting 'no problems', for both rate of change (diff = -26 seconds, $p < .0001$) and wave 2 level (diff = 50 seconds, $p < .0001$). 82% of slow performers at wave 2 reported 'no problems', which is surprising given that they had become even slower over the past two years. Findings suggest that objective FMA measures are needed, as self-report is inaccurate and not prognostic. Future work will examine if discrepancies in performance/perceived FMA predict poorer outcomes, and/or if reporting 'no problems' despite slower performance is protective against cognitive adaptation to slowing.

HEALTH BEHAVIORS IN THE LGB+ POPULATION: VARIATION ACROSS ADULTHOOD

Jessica Noblitt, and Anne Barrett, *Florida State University, Tallahassee, Florida, United States*

Health behaviors, which predict physical and mental health, are patterned by social factors, with some groups engaging in more health-enhancing behaviors than others. LGB+ people face more economic and social barriers to participation in healthy behaviors, along with the stress of discrimination that could lead to unhealthy behaviors to cope. Although some studies have examined variation in health behaviors by sexual identity, they focus almost exclusively on adolescents and young adults. However, such differences may decline across adulthood, as stress related to sexual identity declines with age among LGB+ individuals. Addressing this issue, we use data from the National Health Interview Survey (2016-2018) to examine differences by sexual identity in substance use, weight-related behaviors, healthcare utilization, and sleep. We compare the patterns across three age groups – young, middle-aged, and older adults. Results for each health behavior reveal that differences by sexual identity are indeed greatest among young adults. The magnitude is smaller in middle age, and no significant differences by sexual minority status are observed at older ages.

THE POSITIVE AND NEGATIVE AFFECT RELATION IN THE CONTEXT OF STRESS AND AGE

Jessica Blaxton,¹ Nicole Nelson,² and Cindy Bergeman,²
1. *Metropolitan State University, Saint Paul, Minnesota, United States*, 2. *University of Notre Dame, University of Notre Dame, Indiana, United States*

Research suggests that the within-person inverse relationship between negative affect (NA) and positive affect (PA) indicates poorer emotional well-being, and this interaffect correlation fluctuates in relation to the context of the individual. Specifically, age, stress, and global PA all relate to changes in the interaffect correlation. The current study uses comprehensive data from the Notre Dame Study of Health & Well Being (NDHWB), which allows us to uniquely examine between-person differences in within-person change and variability in the interaffect correlation, thereby examining these constructs from a process-oriented perspective. Midlife and later life participants ($N = 965$) completed daily questionnaires assessing stress, NA, and PA. Three-level multi-level models illustrated that the interaffect correlation becomes more negative during times of stress, adults with greater global PA experience a stronger inverse interaffect correlation during times of stress, and days of higher stress

relate to a stronger inverse interaffect correlation for older adults compared to midlife adults. The findings illustrate the idiographic nature of these relationships and suggest that later life adults and adults with high levels of global PA undergoing higher than typical stressful situations experience stronger inverse interaffect correlations.

TRAJECTORIES OF FUNCTIONAL HEALTH FOLLOWING STROKE: THE ROLE OF SOCIAL RESOURCES

Takeshi Nakagawa,¹ Taiji Noguchi,¹ Ayane Komatsu,² Masumi Ishihara,¹ and Tami Saito,¹
1. *National Center for Geriatrics and Gerontology, Obu, Aichi, Japan*, 2. *Center for Gerontology and Social Science, Research Institute, National Center for Geriatrics and Gerontology, Obu, Aichi, Japan*

Stroke is one of the major causes of disability in old age. Predictors for the functional prognosis have been studied, but the role of social resources in recovery has not studied as much. We examined whether social resources available before and after stroke onset improved functional prognoses. Data was derived from longitudinal data collected between 1987 and 2006 from Japanese adults aged 60 years and older. We identified 396 people who had experienced their self- or proxy-reported first stroke during follow-up (age at stroke onset: $M = 76.0$, $SD = 6.9$; 74.2% women). Functional health was measured by self- or proxy-reported activities of daily living. Social resources were indexed as residential status, contact with non-coresident children, social participation, and perceived support. Analyses were adjusted for age at stroke onset, gender, and education. A multiphase growth model showed that functional health typically deteriorated surrounding stroke and gradually declined thereafter. There were also individual differences in the trajectories of functional health. Individuals who more frequently participated in social groups prior to stroke and those who came to participate more frequently thereafter exhibited less functional decline immediately following stroke. Our findings indicate that social participation plays a protective role against adverse prognoses following stroke regardless of when individuals start participating. Inclusive communities would enable older adults to remain independent. Our study was limited in that crucial information about stroke, such as objective measures of initial severity, was not available and that individuals with more severe stroke may have dropped out after the onset.

Session 9345 (Poster)

Long-Term Care Policy II

ASSET TRANSFERS AMONG THOSE ACCESSING THE MEDICAID PROGRAM: ARE WEALTHY OLDER ADULTS GAMING THE SYSTEM?

Jane Tavares,¹ and Marc Cohen,²
1. *LeadingAge LTSS Center @UMass Boston, Boston, Massachusetts, United States*, 2. *University of Massachusetts Boston, University of Massachusetts Boston, Massachusetts, United States*

Medicaid is the largest payer of long-term services and supports and millions of older Americans rely on the

means-tested program for health care coverage. There has been longstanding concern that wealthy older adults are taking advantage of the program by divesting assets in order to qualify for coverage. The existing research on the issue is somewhat dated, does not focus on the question of asset transfer, and often lacks a significant longitudinal view. Thus, questions remain about whether states need to tighten asset eligibility rules to prevent the wealthier older adults from accessing the program. This analysis explores longitudinal data from the Health and Retirement Study (1998 to 2016) to determine the extent to which wealthier Americans age 50 and older engage in asset transfer to access Medicaid. Our findings demonstrate that this may occur among a relatively small proportion of wealthy older adults, and that tightening Medicaid eligibility criteria would likely have a small to modest impact on the financial status of the program.

DIFFERENTIAL EFFECTIVENESS OF THE MINNESOTA SAFE PATIENT HANDLING ACT BY HEALTH CARE SETTING

Christina Rosebush,¹ and Katherine Schofield,² 1. *University of Minnesota, Twin Cities, Minneapolis, Minnesota, United States*, 2. *University of Minnesota Duluth, Duluth, MN, Minnesota, United States*

The Minnesota Safe Patient Handling (SPH) Act requires nursing homes, hospitals, and outpatient facilities to develop comprehensive SPH programs and acquire mechanical lifts. The law was designed to prevent the adverse outcomes of manual patient handling among workers (e.g., musculoskeletal injuries) and care recipients (e.g., falls, skin tears). Reducing manual handling is of particular concern in nursing homes where residents' care needs necessitate frequent lifts and transfers. To date, research has focused on the effects of SPH laws separately in nursing homes and hospitals. Our study aimed to assess whether change in worker injury rate differed between nursing homes and other health care settings following enactment of the 2007 Minnesota law. We used 2005-2017 claims data from a large workers' compensation insurer and assessed the effects of time, health care setting, and their interaction on claim rate using negative binomial regression models. The claim rate for patient handling injuries was highest in nursing homes (2.8/million payroll), followed by hospitals (1.4/million payroll), and outpatient facilities (0.04/million payroll). Across settings, patient handling claims declined by 38% (95% CI 19-53%) between pre-law (2005-2007) and post-implementation (2014-2017). The decline in claims over time did not differ by health care setting (Wald χ^2 for interaction=3.40, $p=0.758$). Our results suggest that nursing homes are successfully addressing the unique mobility needs of their residents in their mandated SPH programs. Future work should seek to describe the magnitude and nature of care recipient injuries caused by lifting and transferring and evaluate trends in care recipient injuries over time.

FAILING TO COMPLAIN: DO NURSING HOMES WITH MORE RESIDENTS WITH DEMENTIA HAVE FEWER COMPLAINTS?

Kallol Kumar Bhattacharyya,¹ Lindsay Peterson,² John Bowlblis,³ and Kathryn Hyer,⁴ 1. *School of Aging Studies, University of South Florida, Tampa, Florida, United*

States, 2. *University of South Florida, Bradenton, Florida, United States*, 3. *Miami University, Oxford, Ohio, United States*, 4. *University of South Florida, University of South Florida, Florida, United States*

The majority of nursing home (NH) residents have Alzheimer's Disease or Related Dementias (ADRD). However, the association of ADRD prevalence and NH quality is unclear. The objective of the current study is to understand the association of NH characteristics, including the proportion of ADRD residents, with the prevalence of NH complaints as an indicator of quality of care and quality of life. We merged data from the ASPEN Complaints/Incident Tracking System with national NH data from the Certification and Survey Provider Enhanced Reports, the Minimum Data Set, the Area Health Resource File, and zip-code level rural-urban codes in 2017. Three groups of NHs were created, including those whose proportion of residents with ADRD was in the top decile (i.e., high-dementia NHs (N=1,473)) and those whose proportion of ADRD residents was in the lowest decile (i.e., low-dementia NHs (N=1,524)). Bivariate results revealed high-ADRD NHs had higher percentages of Medicaid-paying residents, were less likely to be for-profit and chain-affiliated, had lower staffing hours and lower percentages of Black, Hispanic, and Asian residents. Using NHs in the middle deciles as reference, negative binomial regression models showed that having a low proportion of ADRD residents was significantly associated with higher numbers of total complaints ($p<.001$) and substantiated complaints ($p<.001$), whereas having a high proportion of ADRD residents was significantly associated with lower numbers of substantiated complaints ($p=.001$). The findings suggest the proportion of residents with ADRD in NHs is associated with quality, as measured by complaints. Policy implications of these findings will be discussed.

MEANINGFUL ASSESSMENT OR MINIMUM COMPLIANCE: PASRR FOR NURSING HOME RESIDENTS WITH MENTAL ILLNESS

Taylor Bucy,¹ Kelly Moeller,¹ John Bowlblis,² and Tetyana Shippee,¹ 1. *University of Minnesota, University of Minnesota, Minnesota, United States*, 2. *Miami University, Oxford, Ohio, United States*

The Omnibus Budget Reconciliation Act (OBRA) of 1987 included provisions for the Preadmission Screening and Resident Review (PASRR) program, which requires states to create and maintain systems to assess persons with serious mental illness (SMI) seeking NH care. The prevalence of SMI in NHs is increasing, and little is known about the effectiveness of the PASRR program intervention. We conducted 20 interviews with state and national PASRR stakeholders, including assessors, hospital discharge planners, mental health advocates, geriatricians and geriatric psychiatrists. Interview data were triangulated with state provided materials on PASRR collection and implementation. Based on these interviews, we identified four themes: 1) variation in the implementation of federal PASRR legislation across states and jurisdictions, 2) the need for investment in professional development and workforce capacity, 3) lack of usefulness of PASRR in ongoing care planning, and 4) the need to consider the role of age, race/ethnicity, and stigma on quality of care for NH residents with SMI. Stakeholders

agree that PASRR legislation was well intentioned, but also expressed concern regarding the completion of PASRR as an issue of compliance versus meaningful assessment. More work is needed to determine how best to develop and support the care needs of people with SMI, while being mindful of the original goals of deinstitutionalization that prompted OBRA passage. In order to assess the impact of the PASRR program on quality of care and mental health outcomes, further research should take an evaluative approach through meaningful use of PASRR data.

PREVENTABLE? LONG-TERM CARE POLICY SUCCESSES AND FAILURES DURING COVID-19 PANDEMIC: A SCOPING LITERATURE REVIEW

CHAORAN WU,¹ Aleksandra Zecevic,² Maxwell Smith,³ and Shannon Sibbald,¹ 1. *University of Western Ontario, London, Ontario, Canada*, 2. *Western University, London, Ontario, Canada*, 3. *University of Western Ontario, University of Western Ontario, Ontario, Canada*

The number of older adults who live in long-term care (LTC) is expected to increase worldwide. The COVID-19 pandemic has caused serious consequences in Canadian LTC homes, while homes in China and Japan reported minimal infection and death rates in residents. The differences in LTC policies may be one of the contributors. The purpose of this literature review was to identify elements of the LTC policies that might have impacted COVID-19 outcomes in LTC homes in Canada, China, and Japan. A scoping review was conducted following the framework proposed by Arksey and O'Malley. Scholarly articles and grey literature published between January 2015 and June 2020 were identified in six databases, four in English (CINAHL, Scopus, ProQuest, and PubMed), one in Chinese (CNKI), and one in Japanese (CiNii), using MeSH terms for LTC and health policy. Grey literature was identified using Google. Data were extracted, summarized and common themes identified through content analysis. A total of 52 articles and 26 grey sources were included in the review based on determined inclusion criteria. They were research articles, reviews, government or association reports, policy briefs, policy documents, and guides. Four common themes of challenges emerged: caregiver workforce, service provision, funding, and physical environments. Three sub-themes were identified for caregiver workforce and service provision. Differences in COVID-19 consequences in LTC homes in the three countries seem to be related mainly to the challenges with the caregiver workforce and the lack of funding. The result suggests Improvements of LTC policies are required, especially in Canada.

SCOPING REVIEW: HOME AND COMMUNITY-BASED SERVICE WAIVER PROGRAMS AND PERSON-REPORTED OUTCOMES

Taylor Bucy,¹ John Mulcahy,¹ Eric Jutkowitz,² and Tetyana Shippee,¹ 1. *University of Minnesota, University of Minnesota, Minnesota, United States*, 2. *Brown University, Brown University, Rhode Island, United States*

State Medicaid programs are rebalancing their long-term care spending from nursing home to home and community-based services (HCBS). Emphasis on person-centered and person-directed care warrants investigation into models of HCBS delivery that promote quality of life. We performed

a scoping review of the literature to catalogue the breadth of the studies describing HCBS waiver programs targeting adults (18+). We identified 757 articles, and after duplicate removal and reconciliation, we excluded articles on children or adolescents, non-peer reviewed reports, international studies, and articles that did not describe HCBS waiver programs. After abstract and title review, 292 articles met our inclusion criteria. Most included articles (22.3%) were single state descriptive evaluations or evaluations of service use patterns among participants. 17.8% of included articles examined multi-state or national variation in program trends, while 17.1% made national program conclusions without a major focus on interstate comparison. Less common were studies examining integrated care or dual-eligibles (7.5%), PACE (3.4%), medication management (3.1%), quality and satisfaction of both consumer and caretaker perspectives (3.8%) and consumer-only perspectives (5.1%). The remaining articles focused on HIV (4.1%), TBI (1.4%) or ID/DD (14.4%) waiver programs. The 8.9% of articles addressing quality and satisfaction consisted mostly of interviews, either with state Medicaid administrators or with care recipients and/or caregivers. Consumer reported satisfaction and unmet care needs were the primary outcomes examined. Given the heightened focus on long-term care as a result of the ongoing coronavirus pandemic, this review justifies further exploration into the delivery and outcomes of state-directed HCBS waiver programs.

THE DEVELOPMENT OF A SELF-APPRAISAL TOOL FOR THE LEVEL OF LONG-TERM CARE SERVICE INTEGRATION.

Yu-Chien Chang,¹ and Ya-Mei Chen,² 1. *National Taiwan University, Taiwan, Taipei, Taiwan (Republic of China)*, 2. *National Taiwan University, Taipei, Taipei, Taiwan (Republic of China)*

Introduction Taiwan is the fastest aging countries in the world. In 2016, Taiwan implemented Long-Term Care Plan 2.0 (LTC Plan 2.0), aims to provide coordinated and integrated LTC services. However, how to assess the level of integration and which integration mechanisms are better applied are still unclear in the literature. This study intended to address a research question regarding "How can agencies measure their level of service integration?" and, therefore, aimed to develop an integration assessment tool—the Taiwanese Self-Assessment for LTC Systems Integration (TwSASI)- for LTC agencies to use to self-evaluate their current "level" of providing integrating LTC services. Methods TwSASI was first developed base on Connie J. Evashwick's (2005) framework and literature review, including four domains: inter-entity planning and management, care coordination, integrated information system, and integrated financing, and 11 dimensions with 51 items. Through the Delphi method, with two rounds of investigation and feedback from 26 experts, RAND/UCLA Appropriateness Method (RAM) was used to assess the consensus regarding the dimensions and items developed and refined the tool content accordingly. Results After two rounds of investigation, four domains remained with 10, 11, 4, and 5 items in each domain respectively. All items reached good experts' consensus with medians of the 30 items' importance, feasibility, and appropriateness all over 8. The Scale Content Validity Index (SCVI) of the 4

dimensions all over than 0.9. Conclusion The TwSASI can be feasible for evaluating the level of LTC service integration in Taiwan. LTC agencies can improve their level of service integration accordingly.

WHO IS COMING TO JAPAN UNDER THE NEW STATUS OF RESIDENCE “SPECIFIED SKILLED CARE WORKERS”?

Noriko Tsukada, *Nihon University, Tokyo, Tokyo, Japan*

The Japanese government created a new status of residence called “Specified Skilled Workers” encompassing 14 job categories that have laborer shortages, including long-term care (LTC) workers on April 1, 2019. A survey of students (N=79) at a language institute in Manila, Philippines was conducted in February, 2020 to explore characteristics of future foreign LTC workers in Japan under this new status of residence and identify factors that may help facilitate worker retention. At the time of data collected, these students were studying both Japanese and LTC practices in order to pass skill evaluation tests to enter Japan. Students were asked their perceptions of long-term care, planned lengths of stay, concerns about staying in Japan, and future career plans. Preliminary analyses revealed that 67 (88%) were single, 74(93.7%) had graduated from universities, and a half of them had a nursing background. Most students (93.7%) showed interest in an extended stay in Japan, with some interested in taking the national certified care worker examination which permits extended work in Japan. The most cited concern about being in Japan was “weather, climate and typhoons” (28.1%), followed by “language proficiency” and “living expenses” (21.9%) respectively. As Japan has limited immigration policies but a large need for LTC workers, it is imperative to understand how to attract and retain foreigners who obtain the Specified Skilled Worker status. This includes addressing both work-related and living-related concerns and needs.

Session 9350 (Poster)

Long-Term Care Practice

DIRECT CARE WORKERS EMPLOYED AS MEDICAL AIDES: HOME HEALTH AIDES, NURSING ASSISTANTS, AND ORDERLIES

Christopher Kelly, and Jerome Deichert, *University of Nebraska at Omaha, Omaha, Nebraska, United States*

Purpose: This study describes the differences among direct workers (DCWs) employed as medical aides in three occupations: home health aides, nursing assistants, and orderlies. Design and Methods: Data were from the 1% Public Use Microdata Sample (PUMS) of the 2019 American Community Survey (ACS). Logistic regression was used to compare demographic and employment characteristics of DCWs employed as medical aides in three occupations: home health aides, nursing assistants and orderlies. Results: Compared to orderlies and psychiatric aides, home health aides are more likely to be foreign born, more likely to be female, less likely to work in institutional settings, less likely to be under age 25, less likely to work year-round full-time, less likely to have more education, and less likely to receive

insurance from their employers. Implications: Since 2018, the PUMS of the ACS separates nursing, psychiatric, and home health aides (previously one occupational category) into three: home health aides, nursing assistants, and orderlies. This affords researchers a more precise understanding of this part of the direct care workforce. Home health aides represented more than 2/3 of DCWs employed as medical aides in 2019. Further, these workers are distinct among medical aides. More than nursing assistants and orderlies, home health aides are older, female, underinsured, foreign-born, and with limited education. This reflects both the barriers home health aides face to other occupations and also the preferences of their employers (which include private households). These findings have implications for the recruitment and retention of medical aides across all three occupations.

DO PERSONALITY AND BELIEF INFLUENCE THE OWNERSHIP OF PRIVATE LONG-TERM CARE INSURANCE?

Shu-Chuan Jennifer Yeh,¹ Hsueh-Chih Chou,² and Shih-Hua Sarah Chen,³ 1. *National Sun Yat-sen University, Kaohsiung, Kaohsiung, Taiwan (Republic of China)*, 2. *Kaohsiung Veterans General Hospital, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan (Republic of China)*, 3. *The University of Chicago, Chicago, Illinois, United States*

Long-term care is the largest out-of-pocket expenditure risk for the elderly. Private long-term care insurance is one crucial source to cover the gap. The study aims to investigate (1) whether wealthy people are more likely to purchase private long-term care insurance (LTCI); (2) whether personality traits are associated with ownership of LTCI; and (3) whether individual experience influences the ownership of private LTCI. We surveyed 375 participants for three groups, including nurses, executive MBA, and MBA students. EMBA group had highest percentage of personal discretionary income (defined as greater than 1,780 US dollar per month) (77.6%), followed by MBA group (17.6%) and nurse group (8.8%). The nurse group had highest in long-term caring experience for sick family members (46.4%), self-experience catastrophic diseases (11.2%), and number of family/relatives/friends share responsibilities of caregivers (2.33 persons). The nurse group had lowest risk propensity score as well as openness to experience traits. The percentage of ownership in private LTCI was 48%, 45.6%, and 28.8% for nurse, EMBA, and MBA groups, respectively. After controlling for age and tenure, results from logistic regression indicated that MBA group was less likely to own LTCI compared with nursing group. Compared with less than 30,000, only personal discretionary income 30,001~ 50,000 had higher odds ratio to own LTCI. Wealthy is inconclusive in determining ownership of private LTCI. Nurses who were lowest risk propensity and openness traits and have more sickness experience were more likely to purchase private LTCI. Believe needing LTCI is the strongest predictor in ownership of LTCI.

DO YOUNG ADULTS SEE VALUE IN ADVANCE DIRECTIVES?

Arianna Stone,¹ Yuchi Young,² Taylor Perre,³ Kuo-Piao Chung,⁴ and Ya-Mei Chen,⁵ 1. *University at*

Albany School of Public Health, Albany, New York, United States, 2. State University of New York at Albany, Rensselaer, New York, United States, 3. University at Albany, Rensselaer, New York, United States, 4. National Taiwan University, School of Public Health, Taipei, Taipei, Taiwan (Republic of China), 5. National Taiwan University, Taipei, Taipei, Taiwan (Republic of China)

Many Americans avoid end-of-life care planning; only 26% have completed an advance directive (AD). An AD promotes end-of-life care with dignity allowing individuals to make end-of-life treatment and care decisions before they are unable to do so. Previous studies related to ADs are focused on older adults with serious illness or people with functional/mental disability. The objective of this survey is to better understand young adults' knowledge of and attitude toward ADs and their preferences for ADs related to treatment and care options. Methods. Participants include graduate students ($n=25$) attending a state university in New York State (NYS). Data were collected using two ADs (Five Wishes; Medical Orders for Life-Sustaining Treatment (MOLST)) and one survey questionnaire. Summary statistics and multivariate models will be used to address the study aims. Results. Preliminary results show the average age was 23 years, 72% were female, 48% White, and 44% Black. The majority of young adults hadn't completed an AD; however, their attitude toward ADs was positive; the majority believe it is important to have an AD prepared at their current age; and they believe young adults would willing to fill out ADs. Young adults can make difficult treatment and care decisions when the situation requires it. Conclusion. The study findings can be useful to policy makers, healthcare providers and other stakeholders in promoting population-based healthcare decision-making. Limitation. Participants were recruited from one university in NYS; thus, the study results may be generalized to a population sharing similar characteristics.

EFFECTIVENESS OF SUPERVISION ON WORK ENGAGEMENT AND TURNOVER INTENTION OF CARE MANAGERS IN JAPAN

Ryosuke HATA, *Hokusei Gakuen University, Sapporo, Hokkaido, Japan*

In Japan, care managers engage frail older adults to support their assisted living in long term care insurance system. However, due to the lack of some or all supervision, many care managers face problems such as low work engagement and high turnover rate. This study aims to examine what types of supervision have positive effects on work engagement and turnover intentions of care managers in Japan. The sample of 241 care managers were asked whether they have received individual supervision in the workplace (ISVW), individual supervision in the community (ISVC), group supervision in the workplace (GSVW), or group supervision in the community (GSVC). Independent samples t-tests and one-way ANOVAs were conducted to examine the effectiveness of each types of supervision on work engagement and turnover intension. T-tests showed that only GSVW was significantly related to work engagement ($t=-2.06$, $p<0.05$). Whereas, only ISVW had a significant effect on turnover intentions ($t=2.37$, $p<0.05$). One-way ANOVAs revealed that 28 care managers receiving GSV had significantly higher

work engagement than 92 care managers who did not receive any SV ($F=5.33$, $p<0.01$). 40 care managers receiving both ISV and GSV showed significantly lower turnover intentions than 92 care managers who received neither ISV nor GSV ($F=2.84$, $p<0.05$). Since the results have implications for the importance of supervisions to enhance work engagement or to reduce turnover intension of care managers, a larger sample will need to confirm these effects.

EVIDENCE-BASED RECOMMENDATIONS TO INFORM BEST PRACTICES FOR LGBTQ OLDER ADULTS IN LONG-TERM CARE SETTINGS

Katherine Fasullo,¹ Erik McIntosh,¹ Susan W. Buchholz,² Todd Ruppert,³ and Sarah Ailey,¹ *1. Rush University, Chicago, Illinois, United States, 2. Michigan State University, East Lansing, Michigan, United States, 3. Rush University College of Nursing, Chicago, Illinois, United States*

Lesbian, gay, bisexual, transgender, and queer (LGBTQ) older adults are more likely to live alone and have less familial support, which disproportionately contributes to a reliance on long-term care facilities as they age. Best-practice guidelines supported by scholarly literature to care for LGBTQ older adults in long-term care settings do not exist. This review synthesizes literature about LGBTQ older adults in long-term care facilities and provides recommendations for best practice guideline development. Four electronic databases were searched in June 2019 for studies conducted between 2000 – 2019 related to caring for LGBTQ older adults in long-term care settings. An integrative literature review was completed on the twenty eligible studies. Findings showed that LGBTQ participants fear discrimination in long-term care leading to the invisibility of their identities. They recognize a need for increased staff training and the importance of community networks and facility preferences. Long-term care staff have mixed experiences with inclusive practices and complex views of LGBTQ older adults. They experience training deficits and have a need for more expansive training modalities. The recommendations offered by both LGBTQ participants and long-term care staff are to revise policies and forms as well as provide widespread training and education. LGBTQ participants recommend that their unique identities be recognized within long-term care while long-term care staff recommend leadership involvement to change culture and practice. This review provides evidence-based recommendations to promote equitable healthcare to the LGBTQ older adult population and calls to attention the need for long-term care settings to uniformly follow best-practices.

INTERGENERATIONAL ENGAGEMENT IN RESIDENTIAL SETTINGS: A SCOPING REVIEW OF THE LITERATURE

Andrea Gardiola,¹ Raza Mirza,² Amanda Bull,³ Christopher Klinger,² Jessica Hsieh,² and Samantha Peck,⁴ *1. Queen's University, Toronto, Ontario, Canada, 2. University of Toronto, Toronto, Ontario, Canada, 3. University of Toronto, Whitby, Ontario, Canada, 4. Family Councils of Ontario, Toronto, Ontario, Canada*

Intergenerational engagement provides a rich environment for people of different ages to come together and exchange life stories, skills, and knowledge. Today,

intergenerational interactions are decreasing, however, these exchanges can have positive implications for seniors in residential care homes (RCHs) and younger persons. A scoping review following Arksey and O'Malley's five-step framework was conducted to investigate the impact of intergenerational engagement and programs (IGPs) on older adults in RCHs. A systematic search of ten electronic databases and hand search of references was carried out; thematic content analysis to established key themes. A total of 1,183 academic and grey literature sources were reviewed, with 66 full-text studies assessed for eligibility. Of these sources, 35 studies met inclusion criteria. Studies highlighted four main themes: 1. Types of IGPs, 2. Psycho-social benefits for older adults and improved status among elders with cognitive impairments, 3. Younger person benefits, suggesting reduced ageism and improved social and communication skills, and 4. Program recommendations, including the need for enthusiastic program facilitators, coordination between facilities, sensitivity training for younger persons, detailed advertisements, and appropriate activities for different age groups. Findings inform future practice and research, highlighting that IGPs are an effective strategy to alleviate negative health outcomes for seniors in RCHs. Future research is needed to evaluate long-term effects and further health outcomes. IGPs provide an opportunity to facilitate purposeful and reciprocal relationships between generations, fostering intergenerational understanding. By studying IGPs and intergenerational interactions, we can better determine practices that meaningfully engage elders in RCHs in Canada.

IS HIGHER NURSE AIDE RETENTION ASSOCIATED WITH FEWER NURSING HOME ALLEGATIONS AND COMPLAINTS?

Katherine Kennedy, *LTSS COIN Providence VA Medical Center*

Consumer voices are often left out from assessments of nursing home (NH) quality. For this reason, consumer allegations and complaints against nursing homes were studied in relation to facility rates of nurse aide retention. Analyses involved means and frequencies, correlations, ANOVAs with Tukey correction to examine the independent and dependent variables (N=690). Four quartiles of retention were created. In the final models, medium, high, and extremely high retention facilities are compared to the low retention facilities. Negative binomial regressions were estimated on total, substantiated, and unsubstantiated counts of allegations and complaints. All regressions controlled for the same characteristics, including nurse aide empowerment, consistent assignment, administrator turnover, director of nursing turnover, average age of residents, and percent female. The correlation between retention and the dependent variables was negative and statistically significant ($r=-0.11$, $p<.01$). The ANOVAs showed that high retention NHs (61-72%) received significantly fewer allegations than low (0-48%) and medium (49-60%) retention NHs; they also received fewer unsubstantiated allegations, and fewer complaints, both substantiated and unsubstantiated. After controlling for other variables, each retention group was significantly related to having fewer allegations and complaints compared to the low retention NHs. Notably, high retention NHs received between 29 and 35% fewer allegations and complaints of all

types. Unexpectedly, extremely high retention NHs had more allegations, complaints, and unsubstantiated allegations than high retention NHs. Policy and practice have a role to promote nurse aide retention, improve job quality, and ensure adequate support for this critical, in-demand workforce.

SUPPORT FOR ADJUSTING THE INTENTIONS OF FAMILY MEMBERS AND USERS REGARDING CARE SERVICE USE: AIMED AT CARE MANAGEMENT

Kazutaka Masuda, *Mukogawa Women's University, Nishinomiya, Hyogo, Japan*

In Japan, there are key healthcare professionals for home nursing care for elderly people called Care Managers. The care manager coordinates the service while adjusting the family situation and the user's intentions. The purpose of this study was to examine the practical structure of support for adjusting the intentions of family members and users regarding care service use. Data from seven cases, where family members and users have different intentions regarding care service use, were analyzed using the grounded theory approach. The phenomenon of "confirmation of discrepancies" was discovered with six sub-categories: adjusting the intentions of users and their families, effort to restore relationships, expression of intention to refuse involvement, expression of desire for adjustment, arrangement of opportunities for adjustment of intentions, and appropriate service adjustment. Four patterns occurred in the process of "confirmation of discrepancies": smooth adjustment, restoration and promotion of mutual relationships, failure to reach an agreement, and negative feedback loops. These patterns were based on a combination of the care managers' degree of understanding strength, the managers' degree of insistence, the managers' degree of representation of mutual feelings, the degree of managers' prediction of life prospects, the degree of trust in care managers, and the degree of expression of family anxiety.

THE PRESERVATION OF SPOUSAL AND PARTNER RELATIONSHIPS AMONG NURSING HOME RESIDENTS

Shanae Shaw,¹ and Ellen Csikai,² *1. Alabama State University, Calera, Alabama, United States, 2. The University of Alabama, The University of Alabama, Alabama, United States*

The decision to seek placement in a nursing home may be especially difficult for spouses or partners of the potential nursing home residents. Disruption of the attachment relationship following placement may influence the psychosocial well-being of nursing home residents. Although the responsibility of nursing home staff is to ensure psychosocial well-being, including awareness of the influence that separation can have on a spousal or partner relationship, little is known about services offered for the maintenance of spousal and partner relationships. This study was conducted to identify nursing home practices that had preservation of spouse/partner relationships as the goal. A mixed methods approach utilized both an online survey (81 respondents) with nursing home social workers in four Southern states and ten telephone interviews (from among the respondents). Survey results revealed that 49% of respondents' facilities had a written policy to preserve these relationships, however,

only 22% reported having a specific formal program to carry this out. In the interviews, participants expanded on survey topics and shared that facilitating outings and encouraging participation in routine facility activities were commonly used to preserve relationships. Privacy was discussed as being important in maintaining relationships and also found to be a barrier to doing so. Nursing home social workers can utilize the results in the design and implementation of specific services to preserve relationships and maintain strong attachment between residents and their spouses/partners. These will be best carried out in a coordinated, collaborative manner among multiple disciplines within the nursing home setting.

WHEN ADVOCATES ARE FORCED TO GO VIRTUAL: THE LONG-TERM CARE OMBUDSMAN RESPONSE TO COVID 19

H. Wayne Nelson,¹ F. Ellen Netting,² Mary W. Carter,¹ and Bo Kyum Yang,¹ 1. *Towson University, Towson, Maryland, United States*, 2. *Virginia Commonwealth University, Richmond, Virginia, United States*

This study explores strategies used by the nation's Long-Term Care (LTC) Ombudsman Programs (LTCOP) to perform their grass roots, investigatory, sentinel defense advocacy during the near total COVID LTC lock out from March 13th 2020 through September 17th, when the "ban" was conditionally lifted. Our layered systematic searches by title, subject, and total text for unrestricted allusions to the LTCOP used the multi-disciplinary database Academic Search Ultimate that includes mass media. Selection criteria included print and broadcast news. Search keywords were "ombudsman" singly and with 10 other terms. This was augmented by reviewing the National LTC Ombudsman Resource Center (NORC) clearinghouse information website and by interviewing NORC staff. Resulting (172) media entries (92% print) were manually coded independently by a team of five, and iteratively reconciled according to a simple flat frame format to identify key words and associated themes. Four main LTCOP lock out strategies emerged: (1) virtual resident interventions (via phone, Skype, Zoom, in-facility allies); (2) public outreach (services provided, sharing COVID data and best practices, social isolation threats and mitigation efforts [window visits], need for volunteers); (3) systems advocacy (state/federal; CMS, legislative and other testimony about social isolation, CARES Act check problems, visitation issues; and (4) partnering with others (multi-agency planning groups, task forces, Zoom town halls, interstate information sharing). NORC interviews revealed that older LTCOP volunteers are seizing the COVID lock-out to retire undermining an already short-staffed network—so calls for volunteers were evident in about 25% of all stories regardless of any other focus.

WHEN IS A NURSING HOME COMPLAINT REALLY A COMPLAINT? MAKING SENSE OUT OF INCREASED COMPLAINTS IN U.S. NURSING HOMES

Xiao Qiu, Jane Straker, and Katherine Abbott, *Miami University, Oxford, Ohio, United States*

Official complaints are one tool for addressing nursing home quality concerns in a timely manner. Similar to trends nationwide, the Ohio Department of Health (ODH) has

noticed a trend in increasing nursing home complaints and has partnered with the Scripps Gerontology Center to learn more about facilities that receive complaints. Greater understanding may lead to proactive approaches to addressing and preventing issues. This study relies on two years of statewide Ohio nursing home complaint data. Between 2018 and 2019, the average complaint rate per 100 residents went from 6.59 to 7.06, with more than 70% of complaints unsubstantiated. Complaint information from 629 Ohio nursing homes in 2018 was linked with Centers for Medicare and Medicaid Services Nursing Home Compare data, the Ohio Biennial Survey of Long-Term Care Facilities, and Ohio Nursing Home Resident and Family Satisfaction Surveys. Using ordered logistic regression analyses, we investigated nursing home providers' characteristics using different levels of complaints and substantiated complaints. Findings suggest that providers with higher complaint rates are located in urban areas, had administrator and/or director of nursing (DON) turnover in the previous 3 years, experienced decreased occupancy rates, had reduced nurse aide retention, and received lower family satisfaction scores. Additionally, providers with administrator and/or DON turnover, and low family satisfaction scores are more likely to have substantiated complaints. Because increasing numbers of complaints are accompanied by relatively low substantiation rates, policy interventions targeted to specific types of providers may improve the cost-effectiveness of complaint resolution, as well as the quality of care.

Session 9355 (Poster)

Long-Term Supports and Services

BURNOUT, COMPASSION SATISFACTION, AND PERSONALITY AMONG NURSING ASSISTANTS: WHO IS AT RISK?

Mallory Richert, *Xavier University, Cincinnati, Ohio, United States*

Nursing assistants often experience high rates of turnover and burnout, which may lead to poor resident care outcomes and quality of life, as well as continued staff shortages and increased workload for nursing assistants. This study examined personality correlates of burnout and compassion satisfaction among 100 nursing assistants employed as nursing assistants in long-term care (LTC) and hospitals throughout the United States. Participants completed the Professional Quality of Life Scale 5 (ProQOL 5) and the Big Five Inventory – 2 Short (BFI-2-S). There was a significant positive correlation between compassion satisfaction and agreeableness, and extraversion, and between burnout and neuroticism. Additionally, there were significant negative correlations between compassion satisfaction and neuroticism, and between burnout and agreeableness, and extraversion. These results indicate which nursing assistants may be more likely to experience burnout and may be at an increased risk of turnover. Specific interventions may be developed for such individuals to increase compassion satisfaction, reduce burnout, and reduce staff turnover. Furthermore, information regarding personality types of individuals at greater or lesser risk for burnout may be helpful for LTC administrators in the

recruitment and hiring of nursing assistants, and thus may reduce rates of turnover. Resident care outcomes may also improve as nursing assistant hiring efforts are focused more on individuals who are less likely to experience burnout. Future researchers might investigate potential risk and protective factors for burnout and compassion satisfaction in nursing assistants.

CARE AIDES' PERCEPTIONS OF CARING FOR NURSING HOME RESIDENTS WITH PAST PSYCHOLOGICAL TRAUMA

Trina Thorne,¹ Heather Titley,¹ Peter Norton,² Ruth Lanius,³ and Carole Estabrooks,¹ 1. *University of Alberta, Edmonton, Alberta, Canada*, 2. *University of Calgary, University of Calgary, Alberta, Canada*, 3. *University of Western Ontario, London, Ontario, Canada*

The dynamic interplay between dementia and psychological trauma can exert powerful effects on nursing home residents' behavioral symptoms and quality of life. Our objectives in this exploratory study were to assess care aides' perceptions of how often they worked with residents with past psychological trauma, the types of trauma encountered, and reasons for these beliefs. We conducted semi-structured cognitive interviews (n = 10) with care aides in June 2019 to inform the development of a trauma needs assessment (4 questions) that we included in a large survey of nursing staff (2019 - 2020). Care aides (n = 3761) were sampled from 91 randomly selected urban nursing homes stratified by health region, owner operator model, and size. We completed basic statistics and content analyses. Care aides identified residents they believed to have psychological trauma histories and provided reasons for their beliefs. Approximately 12% of the reported traumatic events were disclosed to staff. The most common, broad categories of trauma to emerge during analysis were abuse (40%) and war exposure (30%). Each had sub-categories. The most common categories of signs of trauma were re-experiencing symptoms such as flashbacks and nightmares (28%), and avoidance of specific triggers, such as water or intimate care (24%). The majority of the reported signs of trauma were persistent and distressing for staff and residents. Some behaviours assumed to be responsive behaviours of dementia may relate to traumatic stress symptomatology. Implementing trauma-informed supports for residents and care aides is essential to person-centred care and optimal quality of life.

DEMENTIA CARE COACHING: A PILOT TO EVALUATE ACCEPTABILITY AND FEASIBILITY IN CARE COMMUNITIES

Lorna Prophater,¹ Boeun Kim,² Basia Belza,² Sarah Cameron,³ and Sam Fazio,¹ 1. *Alzheimer's Association, Chicago, Illinois, United States*, 2. *University of Washington, Seattle, Washington, United States*, 3. *Alzheimer's Association, Dayton, Ohio, United States*

The Alzheimer's Association (AA) Dementia Care Practice Recommendations (DCPR) outline ten recommendations to achieve quality care with a person-centered focus. The AA has developed tools to assist care communities (CC) to evaluate their status within the recommendations by working with a trained coach to maximize adoption and

implementation of these recommendations. The purpose of this pilot was to evaluate the acceptability and feasibility of pairing trained DCPR coaches with CC teams to implement the DCPR tools. Seven CCs were recruited and four received the DCPR overview and self-assessment. Of the four CC, one withdrew and did not receive the intervention. The remaining three were located in a suburban area, nonprofit, and with memory care units. Data was collected from November 2019 through March 2020. Nine CC staff participated with a mean age 35.8 years and had worked for 11.8 years. Baseline mean scores on the Organizational Readiness to Implementing Change (ORIC) scale were 4.6 for the commitment domain and 4.4 for the efficacy domain. Mean scores on the Nursing Home Employee Satisfaction Survey were high. Sixty-nine percent of CC participants were satisfied with their jobs (greater than 4). Findings from mid-project interviews with the coaches revealed difficulty with scheduling appointments, significant efforts needed to get the "right" people at the table and need for the DCPR tools to be more user-friendly. No post-intervention results were collected due to closing of the CCs to visitors due to COVID. The DCPR tools shows promise and are being evaluated in additional CCs.

DEVELOPMENT OF AN ANIMAL-ASSISTED ACTIVITY/THERAPY DOG CHECKLIST FOR LONG-TERM CARE FACILITIES

Karen Dunn,¹ Amy Johnson,¹ and Melissa Winkle,² 1. *Oakland University, Rochester, Michigan, United States*, 2. *American Occupational Therapy Organization, North Bethesda, Maryland, United States*

Animal-assisted activities (AAA) and therapy standards of practice have been published to protect the well-being of animals, animal handlers, and the special populations of patients that benefit from this mode of treatment. Inconsistencies among practice standards with concerns surrounding the topics of dog welfare, human well-being, and zoonotic transmission have been reported. The purpose of this qualitative research study was to review published AAA and therapy standards with older adult populations for best practices, conduct focus group sessions with caregivers from long-term care facilities that allow therapy dog visitation, and synthesize findings into an AAA checklist to be used by long-term care facility decision-makers when interviewing or bringing in therapy dog teams. Comparative analyses utilizing a systematic and sequential approach was used to analyze the data from the focus group sessions. Due to the COVID-19 pandemic, only two focus group sessions at one long-term care facility were conducted resulting in a total of 15 caregivers. Four themes emerged from the data: promotes positive mood, essential resident screenings, caregiver roles, and memory aides. Relevant themes and AAA and therapy standards and guidelines were then combined in the development of the AAA/Therapy Dog Checklist. Administrators may find having a user-friendly AAA/therapy dog checklist a useful tool that can be used when interviewing therapy dog teams to ensure future dog therapy experiences will be positive and safe. The safety and well-being of residents in long-term care facilities and animals are essential to promote positive health outcomes for both populations.

DISTRESS BEHAVIOR CONVERSATIONS: SUPPORTING WHOLE PERSON WHOLE TEAM RESPONSES IN VA COMMUNITY LIVING CENTERS

Julia Loup,¹ Kate Smith,¹ Susan Wehry,² Sharon Sloup,³ Jennie Keleher,³ Princess Nash,³ Christine Hartmann,⁴ and Andrea Snow,³ 1. *University of Alabama, Tuscaloosa, Alabama, United States*, 2. *University of New England College of Osteopathic Medicine, Biddeford, Maine, United States*, 3. *Tuscaloosa VA Medical Center, Tuscaloosa, Alabama, United States*, 4. *VA Bedford Healthcare System, VA Bedford Healthcare System, Massachusetts, United States*

Resident distress behavior, a prevalent challenge in long-term care, contributes to resident morbidity, staff burden, and turnover. We describe an education model developed in the Veterans Administration (VA) Community Living Centers (CLC) through a CONCERT (VA CLCs' Ongoing Center for Enhancing Resources & Training) quality improvement series. The Distress Behavior Conversation (DBC) uses a team meeting structure and process. Informed by unmet need and relational coordination theories, it guides the whole team, inclusive of interdisciplinary team members and front-line staff with resident contact, through a collaborative problem-solving action-planning discussion. DBC uses facilitated round-robins to identify potential resident behavior causes and individualized solutions. DBC supports the team in maintaining whole person and whole team mindsets, thus challenging the narrower medical model of discipline-specific clinical mindsets and staff level hierarchies. Over two years we have co-created and refined DBC through trainings and team debriefings with over 80 CLCs. Care teams reported "aha" moments during DBCs their thinking shifted ("we are now looking at the REAL why"; "we went from asking, how did he fall? to, why did he fall?"; "tended to try to treat falls in a standardized way, [but] when you focus on a specific person you get to focus on HIS needs"; "personal information about the Veteran is the 5th vital sign!"). Teams additionally reported reduced strain and improved collaborative thinking ("I feel better about what I'm doing...more motivated to keep going!"; "Now I see it is a team approach – don't have to do it by myself.").

LEARNING BEST PRACTICES FOR EDUCATING A CAREGIVING WORKFORCE

Sweta Tewary,¹ Yumna Indorewala,² Nicole Cook,³ Naushira Pandya,³ Sashah Damier,¹ and Assma Twahir,³ 1. *Nova Southeastern University, Fort Lauderdale, Florida, United States*, 2. *NSU, NSU, Florida, United States*, 3. *NSU, Davie, Florida, United States*

It is well established that the health professional workforce is not adequately prepared to meet the demands of an aging older population. Caregivers are often the backbone supplemental workforce for seniors, providing daily care with assistance with activities of daily living, with little training. Part of the mission of the South Florida Geriatric Workforce Enhancement Program (SFGWEP) is to support and empower caregivers through community based training programs. Between January 1 2020 to January 31, 2021 SFGWEP provided education to more than 340 caregivers on topics related to opioid use, effective communication with individuals with dementia and other topics. Attendees

responded to a short evaluation survey, which included three multiple-choice questions on if attending was a good use of their time, if they gained knowledge and if they plan to apply material, and two open-ended questions to identify opportunities for improvement in future trainings. Responses were overwhelmingly positive (>98% for multiple-choice questions.) There were also three open-ended questions that were analyzed using a modified thematic approach. The three questions covered what attendees learned, what they wanted to learn more about and suggestions for improvement. Analysis suggests that attendees plan to be more mindful about communication (e.g. improve eye contact, listen more) and that they want more information on neurocognitive disorders and resent research, including psychological changes due to disease and medication side effects. In terms of improvement, attendees said the program should allow more time for questions and should use more engaging materials (polls, posters, flyers and case studies).

MULTIPLE STREAMS ANALYSIS OF THE LONG- TERM CARE INSURANCE IN SOUTH KOREA: UNDERSTANDING POLICY CHANGES (2008 - 2014)

Mijin Jeong, *University of Kansas, LAWRENCE, Kansas, United States*

The Long-Term Care Insurance (LTCI) Act in South Korea was enacted in 2008 to improve the quality of life of older adults by promoting better health and to mitigate the burden of care on family members. In 2014, the Enforcement Decree for the LTCI Act was revised to broaden criteria for eligible recipients of LTCI-related services and care. This policy analysis seeks to explore the political circumstances under which the Act was formed and how social environmental factors had evolved to revise the LTCI Act using a multiple streams policy analysis framework. A combination of factors influenced the status of LTCI policy agenda, including shifts in aged demographic structure and increasing medical expenditures. From the Korean National Dementia Plan, a pilot project of dementia care was conducting to prove the efficiency of dementia care service. While the Korean Senior Citizens Association (KSCA) was less successful gaining press attention around dementia care, the presidential election and candidates' election pledges were key factors to suddenly open the opportunity to extend the recipients for dementia care. The process through which the LTCI Act was revised and expanded showed the importance of the political environment associated with the election. Based on the recognition of LTIC policy agenda and already testing the efficiency of dementia care services, the election led to revision of LTCI Act and it quickly diffused by the new administration. From the revision of LTCI, international policymakers and scholars should recognize how the political events might use the policy for older adults.

PERSONAL CARE AIDES IN RESIDENTIAL CARE AND ADULT DAY CENTERS: DIFFERENCES IN TRAINING, BENEFITS, AND ROLES

Manisha Sengupta,¹ and Farida Ejaz,² 1. *CDC/NCHS, Hyattsville, Maryland, United States*, 2. *Benjamin Rose Institute on Aging, Cleveland, Ohio, United States*

Personal care aides (PCAs), along with other direct care workers, provide the hands-on care, including help with

activities of daily living for individuals receiving care in residential care communities (RCC) and adult day services centers (ADSC). Recruitment and retention of such workers is a challenge as low pay, inadequate training, unsatisfactory roles and lack of benefits contribute to turnover. Using data from the 2018 National Study of Long-Term Care Providers, the only nationally representative data about PCAs in RCCs and ADSCs, this study will assess differences in training hours, benefits, and work roles among PCAs in these settings. About 76% of RCCs and 66% of ADSCs employed aides. On average, PCAs received 32 hours and 51 hours of initial training in ADSCs and RCCs, respectively. Results from bivariate analyses (accounting for complex survey design), showed that benefits received by PCAs varied by sector. A higher percentage of PCAs in ADSCs than in RCCs received health insurance for employees (60% vs. 46%), and pension (51% vs. 40%). About 51% of ADSCs and 46% of RCCs reported that PCAs rarely or sometimes attended care plan meetings. Further, 11% of RCCs and 15% of ADSCs reported that aides rarely or sometimes worked with the same care recipient. This overview of PCA activities, training and benefits may provide insights into approaches to improve the retention of PCAs and subsequently the quality of care provided across sectors.

RESILIENCE AND MENTAL HEALTH AMONG MALE OLDER ADULTS IN EXTREME POVERTY IN LONG-TERM CARE FACILITIES IN RURAL CHINA

Ying Ma,¹ and Patrick Leung,² 1. *University of Houston, Richmond, Texas, United States*, 2. *University of Houston, Houston, Texas, United States*

Older adults in extreme poverty refer to “three-noes people”: no working ability, no income source, and no children or legal supporters. They are eligible for a government-funded welfare system called “Five Guarantee system”. The majority of residents in rural welfare institutes are male older adults in extreme poverty. Research demonstrates that resilience is a critical factor in shaping health. This study aims to examine the association between resilience and mental health for male older adults in extreme poverty, and its differences in young-old (60-69 years), old-old (70-79 years), and oldest-old groups (≥ 80 years). A cross-sectional study was conducted with 1,427 eligible subjects in rural long-term care facilities from Anhui province in China during 2019, with a response rate of 77.4%. Resilience was measured by the Chinese version of Connor-Davidson Resilience Scale, including three subscales of optimism, strength and tenacity. Mental health was assessed using General Health Questionnaire-12. A MANOVA test revealed a significant difference among age groups on three subscales of resilience [Pillai's Trace=.023, $F(6, 1486) = 2.709$, $p = .013$, $\eta^2 = .012$]. Tukey Post hoc indicated the oldest reported significantly lower levels of strength, optimism, and tenacity compared to the other two groups. A multiple logistic regression identified a significant negative association between resilience and mental disorder for the old-old (OR=0.95, 95%CI: 0.93-0.97) and oldest-old (OR=0.93, 95%CI: 0.88-0.99) groups. Our findings identified the differences in the link between resilience and mental health within the three different age groups. Resilience-training programs to improve mental health would require targeting specific subscales of resilience for each group.

ROBOTIC-ASSISTED VIRTUAL CARE

Lillian Hung, *University of British Columbia, Vancouver, British Columbia, Canada*

Heightened isolation during the pandemic has exacerbated the stress, anxiety, and adverse consequences through the loss of family connections older people experience in LTC. Heavy workload and staffing shortage limit staff's capacity to assist residents in accessing regular virtual visits. Using a Collaborative Action Research (CAR) approach, this project aims to assess the implementation of a telepresence robot, Double 3 to help residents connect with their families. CAR allows careful planning of implementation with stakeholders (patient and family partners, staff, and decision-makers), tailoring adaptation to the complex LTC environment. We will program path planning to allow efficient movement between target destinations (residents' rooms) and the charging dock. For example, the robot will go to a resident's room every morning or evening to help the resident to make a virtual call with family. The project involves three phases (a) Observe and Reflect, (b) Act and Adapt, (c) Evaluate. We work with two Canadian LTC homes in British Columbia to investigate feasibility and acceptability. CAR emphasizes research with, rather than research on people. Meaningful engagement with patient and family partners, frontline staff, and decision-makers at each site throughout the whole project will ensure the project will meet the local needs. Anticipated resident outcomes include improved quality of life, mood, perceived loneliness, perceived social support, and acceptance. Anticipated staff outcomes include perceived ease of use, and acceptability.

ROOM TYPE AND SOCIAL COHESION IN SENIOR-LIVING FACILITIES

ZHE WANG, *Henan University, Henan University, Kaifeng, Henan, China (People's Republic)*

Private rooms are generally preferred by senior-living residents. However, having roommates may help residents to build and maintain social networks in the facility, leading to promoted social cohesion and mental health. The differences in social cohesion among senior-living residents who resided in private or shared rooms need investigation. This research collected empirical data from eight senior-living facilities in Beijing and Shanghai, China. Focusing on social cohesion, room type, and personal factors, on-site questionnaire surveys recruited 345 residents receiving independent living, assisted living, or nursing care services. Facility environments were measured and rated by researchers through on-site observation. Controlling for personal and facility factors, ANOVA tests were employed to investigate the differences in social cohesion among residents who resided in private, double, or triple rooms. Room type was found significant to the social cohesion in assisted-living and nursing care residents. At the assisted-living level, compared with private and double rooms, triple rooms were more likely to contribute to social cohesion ($p < 0.01$). At the nursing care level, residents with less numbers of roommates (private versus double and double versus triple) had stronger social cohesion ($p < 0.05$). At the independent-living level, no factors significant to social cohesion were found. These findings can be used to guide the new design, renovation, and modification of senior-living environments to promote social cohesion. Recommendations

for future research and practice implications for senior-living professionals and facility designers are discussed. Senior-living facilities should be built to be social-friendly through design and planning and within the context of its cultural characteristics.

THE INFLUENCE OF STAFF-RESIDENT INTERACTIONS ON RESISTIVENESS TO CARE BEHAVIOR IN ASSISTED LIVING

Rachel McPherson,¹ Barbara Resnick,² and Elizabeth Galik,³ 1. *University of Maryland Baltimore and Baltimore County, Catonsville, Maryland, United States*, 2. *University of Maryland, Baltimore, Maryland, United States*, 3. *University of Maryland School of Nursing, Baltimore, Maryland, United States*

Resistiveness to care (RTC) is a behavioral and psychological symptom of dementia that is common among dementia residents in assisted living facilities. RTC encompasses verbal and nonverbal behaviors that oppose care, such as crying, grabbing, hitting, or yelling, among many other resistive behaviors. The quality of care interactions which can be positive, neutral or negative, have been associated with increased RTC. The purpose of this study was to test the association between quality of care and RTC. This was a secondary data analysis using baseline data from the Function-Focused Care for Assisted Living Using the Evidence Integration Triangle (FFC-AL-EIT) implementation study. Controlling for cognition, age, gender, medication use, and comorbidities, it was hypothesized that quality of care interactions would be associated with resistiveness to care. A linear regression analysis was conducted to test the hypothesis. The sample included 794 participants the majority of whom were white women with a mean age of 89.48 (SD=7.61). The mean RTC was .09 (SD=.41, range 0-13) and the mean quality of care interactions were 5.96 (SD=1.44, range 0-7). Based on the regression analysis there was no significant association between quality of care and RTC. These findings may be due to the high quality of care provided and limited RTC in this sample. Ongoing research is needed, however, to continue to explore these relationships and assure that all RTC is being reported among staff and that there is no evidence of negative quality of care interactions in these settings.

Session 9360 (Poster)

Mental Health (BSS Poster)

AGE, EMOTION REGULATION, AND WELL-BEING AFTER THE 2016 FLOOD

Katie Cherry,¹ Piper Bordes,² Matthew Calamia,³ and Emily Elliott,³ 1. *Louisiana State University, Louisiana State University/Baton Rouge, Louisiana, United States*, 2. *Louisiana State University, Louisiana State University, Louisiana, United States*, 3. *Louisiana State University, Baton Rouge, Louisiana, United States*

In 2016, catastrophic flooding in south Louisiana claimed 13 lives with billions of dollars in damage to homes and communities in the decade after Hurricanes Katrina and Rita devastated the US Gulf Coast. In this study, we tested the inoculation hypothesis which predicts that older adults

will be less distressed than younger adults due to their prior experience with severe weather events. Participants were 218 predominately middle-aged and older adults who varied in current and prior flood experience: less than half (40%) did not flood in 2016, 31% had flood damage, and 29% had relocated permanently inland after catastrophic losses in the 2005 Hurricanes Katrina and Rita and they flooded again in 2016. Depression symptoms were assessed with the 9-item Patient Health Questionnaire (PHQ-9). Emotion regulation strategies were measured using the Cognitive Emotion Regulation Questionnaire-Short Form. Results indicated that the older adults had fewer symptoms of depression and were less likely to report self blame for flood-related adversities compared to younger adults. The two age groups did not differ significantly on the emotion regulation strategies of acceptance, reappraisal, positive refocusing, other blame, and perseveration. Age was inversely associated with symptoms of depression and the maladaptive strategies of self blame for flood-related misfortune and perseveration over losses. These data support the inoculation hypothesis and suggest that prior severe weather experiences, which are likely for older adults living in hurricane prone areas, are important for post-flood resilience. Implications of these findings for disaster planning and age-sensitive interventions to mitigate adversity are considered.

BEST PRACTICES FOR WORKING WITH LATINX OLDER ADULTS IN MENTAL HEALTHCARE

Kendall Weber,¹ and Lisa Stone,² 1. *University of Colorado at Colorado Springs, University of Colorado at Colorado Springs, Colorado, United States*, 2. *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*

Background: The number of older adults in the United States is growing rapidly. The percentage of individuals from ethnic minority groups that make up this population is also rapidly increasing, with Latinx older adults comprising the fastest growing subgroup. However, Latinx older adults historically underutilize mental health services, in large part due to the lack of culturally sensitive and informed care provided by mental health professionals (de Guzman et al., 2015). However, to date, comprehensive, evidence-based best practices for mental healthcare for Latinx older adults do not exist. Method: A literature review was conducted of research on the developmental, social, cognitive, biological, and affective bases of behavior among Latinx older adults. Results: Taking an integrated, evidence-based psychological approach with cultural considerations, we found that the literature could broadly be organized into six best practice guidelines. We propose assessing for and incorporating the following topics into mental health treatment of Latinx older adults: immigration status, acculturation, attitudes towards mental health, physical and cognitive health disparities, discrimination, and unique preferences for care structure in later life. Discussion: These guidelines are intended to represent basic principles to incorporate into practice and do not represent an exhaustive list of factors to consider for a heterogeneous group of older adults. Instead, the six, empirically-based guidelines proposed in this study can serve as a starting point for increasing mental health providers' awareness of the unique experiences of Latinx older adults, with the aim

of improving the experience of this historically underserved population in mental healthcare treatment.

COGNITIVE CHANGES IN OLDER ADULTS FOLLOWING A STEPPED CARE INTERVENTION FOR LATE-LIFE DEPRESSION

Anna Y Zhang,¹ Shiyu Lu,² Tianyin Liu,² Dara KY Leung,² Gloria HY Wong,² and Terry YS Lum,² 1. *The University of Hong Kong, The University of Hong Kong, Not Applicable, Hong Kong*, 2. *The University of Hong Kong, Hong Kong, Not Applicable, Hong Kong*

Older adults with depression may manifest cognitive decline and treating depression may maintain or improve cognition. However, cognitive outcomes could be overlooked in non-pharmacological interventions for depression. This analysis investigated cognitive changes in a stepped-care intervention (Clinical Trial ID: NCT03593889) and the potential association with individual depressive symptom change. The community-dwelling older adults at risk of or with depressive symptoms without significant cognitive impairment (n=802) were assigned to intervention group (n=644) and control group (n=138). Depressive symptoms and cognitive functions were measured using Patient Health Questionnaire-9 and Cognitive Montreal Assessment-5 minutes protocol, respectively. Paired-t-Test showed significant improvements in overall cognition and attention in both intervention and control groups, but the improvements of language fluency (Intervention: MD=-0.51 p<0.01; control: MD=0.14, p=0.500) and orientation (Intervention: MD=-0.22 p<0.05; control: MD=-0.11, p=0.229) only displayed in intervention group. As control group had better cognition at baseline, linear mixed-effects model analysis was used to compare between-group difference. Intervention group had no significant cognitive improvement after adjusting the covariates but a potential improvement in language fluency (Coef. =0.442, SE=0.247, p=0.074). A linear regression analysis in intervention group indicated that reduction of concentration problem ($\beta=0.106$, p<0.05) and retardedness ($\beta=0.117$, p<0.01) under the symptomatology of depression were associated with the improvement of language fluency. In this group of older persons without significant cognitive impairment, there is no clear evidence of global cognitive benefits in a stepped care depression intervention, although there may be improvements in certain cognitive domains, which may be related to improvements in cognitive aspects of depression.

COMPARING COGNITIVE AND PHYSICAL LIMITATIONS AS PREDICTORS OF DEPRESSION AMONG OLDER ADULTS

Clara Scher,¹ Lenna Nepomnyaschy,² and Takashi Amano,³ 1. *Rutgers University, New York, New York, United States*, 2. *Rutgers University, New Brunswick, New Jersey, United States*, 3. *Rutgers University-Newark, Newark, New Jersey, United States*

Depression in older adults is associated with loss of functioning and increased mortality. While many factors contribute to depression among this population, activities of daily living (ADL) limitations and cognitive impairment have been identified as key risk factors. However, no study, to our knowledge, has examined the extent to which physical and cognitive limitations independently and jointly contribute to the risk of

depression. The current study describes the prevalence and compares the independent and joint associations of these limitations with depression in a nationally representative sample of adults aged 51 and older in the US. Analyses are based on a sample of 17,044 repeated observations on 6,636 unique primary respondents from three waves of pooled data from the Health and Retirement Study. We estimate linear and logistic multivariate regression models investigating the association between ADL limitations (any limitation on Katz ADL scale), cognitive impairment (<12 on the TICS-27 scale), and depressive symptoms (8-item CES-D), controlling for a standard set of socioeconomic and health factors. First, we find that 66% of respondents report no limitations, 16% report only cognitive impairment, 11% report only ADL limitations, and 7% report both types of limitations. Multivariate analyses suggest that ADL limitations have a much stronger association with depression compared to cognitive impairment, and this association is robust across alternative specifications. In next steps, we will take advantage of the longitudinal nature of these data to estimate changes in these characteristics over time and within individuals and explore heterogeneity in associations across relevant groups.

DEPRESSIVE AND ANXIETY DISORDERS IN ALCOHOL USE AND RELATED PROBLEMS AMONG OLDER AFRICAN AMERICANS

Tomorrow Arnold, *University of Tennessee at Chattanooga, Chattanooga, Tennessee, United States*

The older African American (AA) population is expected to triple by 2050; however, research on depression, anxiety, and alcohol use among older AAs is lacking. Current mental health and substance use studies involving older AAs often focus on between-race differences, frequently comparing AAs to Whites, without addressing within-group variation in the former. As such, little is known about the associations between depression, anxiety, alcohol use and related disorders in this population. The present study used data from 2016-2017 Midlife in the United States (MIDUS) Milwaukee 2 to examine whether depressive and anxiety symptoms and disorders are associated with alcohol use and alcohol problems among 274 African Americans aged 50 to 93 (62.8% women). Of the sample, 9.5%, 3.6%, and 6.6% met criteria for depression, generalized anxiety (GAD), and panic disorders, respectively. About 8.1% had drunk heavily and 18.5% binge drank in the past month with 10.2% reporting alcohol problems in the past year. Those with depression and those with panic disorder were more likely to be heavy drinkers; while only those with panic disorder were more likely to be binge drinkers. Meeting criteria for depression or panic disorder but not GAD disorder were both more likely to have had alcohol-related problems than those not meeting criteria. Only panic disorder was associated with increased likelihood of drinking more than intended in the past year. Preliminary exploratory findings suggest that the associations between depressive symptoms, type of anxiety disorder, alcohol use, and problems varied by gender.

DEPRESSIVE SYMPTOMS MEDIATE THE INFLUENCE OF FIBROMYALGIA STATUS ON PHYSICAL PERFORMANCE AND BMI IN AGING ADULTS

Dylan Serpas,¹ Laura Zettel-Watson,² and Barbara Cherry,² 1. *California State University, Fullerton, Bonita, California*,

United States, 2. California State University, Fullerton, Fullerton, California, United States

Fibromyalgia is a chronic pain condition that is frequently accompanied by comorbid conditions, including depression. Depression is associated with reduced physical functioning and health disproportionately affecting middle-aged and older adults with fibromyalgia. This study examined depressive symptoms as a mechanism through which FM status is associated with BMI and physical performance among adults in mid-to-late-life. Participants included 250 community-dwelling middle-aged and older adults (82% female) with (59%) or without (41%) fibromyalgia (M age = 64.44, SD = 9.16). Depressive symptoms were measured using the Beck Depression Inventory-II, BMI was objectively assessed, and physical performance was measured using the Fullerton Advanced Balance scale, 6-Minute Walk Test, 30-Second Chair Stand, and 8-Foot Up and Go Test. Physical performance measure analyses were adjusted for age. Asymptotic mediation analyses revealed that fibromyalgia status was indirectly associated with higher BMI (95% CI [.18, 16.74]), and poorer performance in the Fullerton Advanced Balance (CI [-2.93, -1.24]), 6-Minute Walk Test (CI [-73.75, -35.35]), 30-Second Chair Stand (CI [-2.45, -1.16]), and 8-Foot Up and Go test (CI [.35, .92]) via depressive symptoms. Participants with fibromyalgia reported greater depressive symptoms which was subsequently associated with greater BMI and reduced physical performance. Findings support depressive symptoms as one factor through which fibromyalgia status is associated with higher obesity risk and reduced physical function in middle-aged and older adults with fibromyalgia. This study supports fibromyalgia status as a critical consideration when evaluating the health and disability risk of aging adults.

DIFFERENT STATISTICAL APPROACHES TO DEVELOP A GUIDELINE FOR IMPROVEMENT OF CAREGIVER'S MENTAL HEALTH

Amanda Leggett,¹ and Hyun Jung Koo,² *1. The University of Michigan, Ypsilanti, Michigan, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

Caregiver burden is common, and improvement of caregivers' mental health could lead to better quality of care and well-being for both caregivers and care recipients. We investigate ways to develop a guideline to enhance caregiver's mental well-being by applying and comparing regression tree and ensemble tree models. Data comes from the 2017 National Health and Aging Trends Study and National Study of Caregiving. Dementia caregivers' (n=945) aspects of caregiving, care activities, support environment, and participation along with basic demographics and health are considered. First, insignificant predictors are preselected using linear regression with backward selection, which will not be included in the tree models. Using the predetermined predictors that are not excluded in the backward selection method, regression tree and ensemble tree models are generated to predict emotional difficulty of caregivers. The regression tree with the preselected predictors predicts caregivers with low to moderate levels of overload and high levels of joy being with their care recipient associated with the lowest level of emotional difficulty. On the other hand, if caregivers have high levels of overload and low to moderately high

levels of positive affect, this is linked with the highest level of emotional difficulty. Ensemble tree models showed similar results with lower error measures. Using tree-based methods can help determine the most important predictors of caregiver mental health. Easily interpretable results with applicable decision rules can provide a guideline for intervention developers.

EFFECTIVE RECRUITMENT STRATEGIES FOR HOME-LIVING VULNERABLE OLDER ADULTS WITH DEPRESSION INTO A PSYCHOTHERAPY RCT

Eva-Marie Kessler,¹ Fee Hoppmann,¹ Julie L. O'Sullivan,² Paul Gellert,³ and Christina Tegeler,⁴ *1. MSB Medical School Berlin, Berlin, Berlin, Germany, 2. Charité – Universitätsmedizin Berlin, Charité – Universitätsmedizin Berlin, Berlin, Germany, 3. Charité – Universitätsmedizin Berlin 10117, Berlin, Germany, 4. MSB Medical School Berlin, MSB Medical School Berlin, Berlin, Germany*

Objectives: Vulnerable older adults, such as physically impaired or care-dependent individuals, are vastly underrepresented in psychotherapy research. Improving their inclusion in randomized controlled trials is necessary to determine the effectiveness of psychotherapy in this population. This study is the first to systematically evaluate strategies to recruit home-living vulnerable older adults with clinically significant depression into a large randomized controlled psychotherapy trial. Potential participants were approached directly (self-referral) or via cooperation with gatekeepers (gatekeeper-referral). Methods: The initiator of the first contact with the study team and successful recruitment strategies were recorded. Referral strategies were compared with respect to number of inquiries and inclusion rates; study personnel's time investment; and participant characteristics (sociodemographics, functional and cognitive status, depression and anxiety scores). Results: Most of the N=197 participants were included via gatekeeper-referral (80.5%, 95%CI=[74.9%,86.1%]), but time investment for gatekeeper-referrals was five times higher than for self-referral by media reports. Clinical psychologists and medical practitioners referred the largest proportion of participants (32.3% each) and referral by medical practitioners led to highest inclusion rates (55.6%; $\chi^2(3)=8.964$, $p<.05$). Most participants were referred from a hospital setting (50.3%), whereas referral numbers by medical practices were low (15.9%). Participants who initiated the first contact themselves had higher inclusion rates and were less functionally and cognitively impaired. Conclusions: Including home-living vulnerable older adults into psychotherapy trials requires simultaneous implementation of diverse recruitment strategies. Medical practitioners and psychologists, especially in hospitals, are the most effective recruitment strategy, but self-referral via media is most cost-efficient in terms of time investment.

EMOTION REGULATION PROFILES OF DEVELOPMENT OF DEPRESSIVE SYMPTOMATOLOGY: A LONGITUDINAL STUDY.

Teresa Paniagua,¹ Virginia Fernández-Fernández,² and M^aÁngeles Molina Martínez,³ *1. Universidad Europea de Madrid, Majadahonda, Madrid, Spain, 2. Universidad Nacional de Educación a Distancia, Madrid, Madrid, Spain, 3. Universidad Francisco de Vitoria, Madrid, Madrid, Spain*

Introduction: COVID-19 pandemic has had a psychological impact on the eldest population. The aim is to analyse whether there are differences depending on the emotional regulation profile shown by a group of older people 6 months before the pandemic and the depressive symptomatology of these people at the same time, during home confinement and 8 months later. **Method:** Longitudinal study, sample of people over 65, three evaluation measures: WAVE1 (6 months before COVID-19, N=305; M=73.63; 58.9% women), WAVE2 (house confinement; N=151; M=73.14; 59.6% women) and WAVE3 (8 months later; N=91; M=72.62; 64.70% women). We measured depressive symptomatology (CES-D; Radloff, 1977) and nine emotional regulation strategies (CERQ-S; Garnefski et al., 2001; Carvajal et al., 2020), with which 3 clusters were preset (after dendrogram inspection and K means analysis). Three mean difference analyses (one-factor ANOVA) were performed taking as factor profiles and as outcomes variables depression in each wave. **Results:** profile 1, people use adaptive cognitive-emotional regulation strategies; profile 2, those with low levels of strategies (adaptive and maladaptive); profile 3, high scores in maladaptive strategies. Statistically significant differences between profiles 1 and 3, in the pre-confinement depression variable ($F(2,91)=6.18; p=.00$) and during confinement ($F(2,91)=4.02; p=.02$). Profile 3 higher depressive symptomatology ($\bar{x}_1=17.16; \bar{x}_2=16.80$) than 1 ($\bar{x}_1=8.41; \bar{x}_2=9.65$). Differences between profile 1 and 2 and 3 in depression 8 months after confinement ($F(2,91)=4.02; p=.02$). Profile 1 lower levels of depression ($\bar{x}_3=98.00$) than 2 ($\bar{x}_3=15.78$) and 3 ($\bar{x}_3=14.20$). Profiles explain 12.3%, 8.4% and 12.5% of the depression variance in each wave. **Conclusions:** a "protected profile" (1), a "medium-term vulnerable profile" (2) and a "vulnerable profile" (3) to the development of depressive symptomatology.

EMPIRICALLY EVALUATED SUICIDE PREVENTION PROGRAM APPROACHES FOR OLDER ADULTS: A SYSTEMATIC REVIEW

Vivian Miller,¹ Noelle Fields,² Ling Xu,² Marta Mercado-Sierra,³ and Marissa Wallace,² 1. *Bowling Green State University, Bowling Green, Ohio, United States*, 2. *University of Texas at Arlington, Arlington, Texas, United States*, 3. *Texas A&M Commerce, Commerce, Texas, United States*

Suicide is a serious public health concern, particularly for individuals in later life. Studies suggest that greater attention to suicide prevention programs for older adults is needed as well as continued research related to interventions with older adults at risk of attempting suicide. A systematic review of the literature on suicide prevention treatment and effectiveness is fundamental to assessing existing services and developing new programs and practice standards. This systematic review of the literature extends an earlier and well-cited systematic review (1966-2009) by examining articles published between 2009 and 2021 with a focus on what types of empirically evaluated suicide prevention programs effectively prevent and reduce suicidality in older adults. The Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines were used to gather the appropriate extant research and improve reporting accuracy. A three-stage review guided the

selection of the articles. At stage one, titles were screened, which excluded 284 articles based on the inclusion criteria. Second, after a full review of each abstract, a final 14 articles remained for full-text review. Lastly, three independent researchers reviewed each of the full-text articles, and six articles were excluded. The final sample includes eight articles (N=8). The articles were categorized into three types of programs: 1) primary and home health care, 2) community-based outreach, and 3) counseling. Following a description of the articles, the authors assessed each study using the GRADE rating system. Findings underscore the critical need for evidence-based suicide prevention programs for older adults. Implications for future research are offered.

EXAMINING MEASUREMENT INVARIANCE OF DEPRESSION AMONG MALE AND FEMALE IN CHINESE OLDER ADULTS

Roberto Melipillán,¹ and Mengyao Hu,² 1. *Universidad del Desarrollo, Concepcion, Bio-Bio, Chile*, 2. *University of Michigan, Ann Arbor, Michigan, United States*

Depression of older adults is an important public health concern. With the increasing popularity of cross-cultural research and comparison studies, researchers are facing a difficult problem: responses to the depression scales obtained from different population groups may not always be comparable. This study examines the measurement invariance of the 10-item version of the Center for Epidemiological Studies Depression (CES-D) Scale across male and female in Chinese older adults. Data are drawn from the baseline wave of the China Health and Retirement Survey (CHARLS), a national survey conducted biennially with a sample of the Chinese population who are 45 years of age or older. The final sample size includes 15,977 respondents; 53.2% of whom are female. The mean age for the sample is 58.3 (SD = 10.2). Measurement invariance (MI) tests based on Multiple Group Categorical Confirmatory Factor Analyses (MGCCFA) was performed. Results show that full scalar model was not supported, and question items invariant across groups were identified. These results indicate that any mean comparisons of CES-D across Chinese male and female older adults not accounting for the noninvariance in the items could be biased, highlighting the importance of performing MI tests before conducting mean comparisons across groups.

HOW DO ALCOHOL USE AND DEPRESSION PREDICT GRIP STRENGTH AMONG MIDDLE-AGED AND OLDER ADULTS?

Song Ge,¹ Linda Dune,² Desiree Frantz,² Laurel Laviolette,² Mary Njuguna,³ xianping tang,⁴ and Changwei Li,⁵ 1. *University of Houston-Downtown, University of Houston-Downtown, Texas, United States*, 2. *University of Houston Downtown, Houston, Texas, United States*, 3. *University of Houston downtown, Richmond, Texas, United States*, 4. *Xuzhou Medical University, Xuzhou, Jiangsu, China (People's Republic)*, 5. *Tulane University School of Public Health and Tropical Medicine, New Orleans, Louisiana, United States*

Background: Physical performance is an important indicator that reflects current and predicts future health. In this study, we examined the association of alcohol use and depression with grip strength a national sample of middle aged and older Chinese adults. **Methods:** We used the baseline data

from the China Health and Retirement Longitudinal Study (CHARLS) and constructed a multivariate linear regression using SAS 9.4 to examine the independent association of alcohol use (never, former, moderate, and at-risk drinkers) and depression with grip strength controlling for socio-economic factors and domestic partner status. Results: The study population consisted of 12,488 Chinese adults (mean age 59). The prevalence of ever drinking during lifetime and current at-risk drinking (>14 standard drinks [one standard drink contains 14 grams of pure alcohol] per week) in this population was 25.7% and 15.2% respectively. 28.4% of the study population had depression. Compared with never drinkers, moderate and at-risk alcohol use were independently associated with better grip strength ($P < 0.0001$). Depression was independently negatively associated with grip strength ($P < 0.0001$). Conclusions: We found that current alcohol use might be protective of grip strength while depression might be detrimental to grip strength among middle-aged adults. However, the underlying mechanism is unclear. Given the negative impact of alcohol and depression on adults' overall health, clinicians should assess alcohol use and depression in middle-aged and older patients using validated tools and provide resources. Clinicians should counsel patients that if depression is not managed, patients may suffer from depression associated health consequences such as declined grip strength.

INFLUENCE OF DEPRESSION AND PERSONALITY ON SOCIAL FUNCTIONING IN OLDER ADULTS

David Freedman,¹ George Lederer,² Lauren Atlas,³ Rachel Waldman,⁴ Jennifer Ho,⁵ Helene Geramian,⁵ Dmitry Francois,⁶ and Richard Zweig,⁵ 1. *Lenox Hill Hospital, Brooklyn, New York, United States*, 2. *Jacobi Medical Center, Scarsdale, New York, United States*, 3. *New York-Presbyterian/Columbia University Irving Medical Center, NEW YORK, New York, United States*, 4. *Weill Cornell Medicine, New York, New York, United States*, 5. *Yeshiva University, Bronx, New York, United States*, 6. *NY, White Plains, New York, United States*

Among older adults there is significant comorbidity between depression and personality pathology and both are associated with poorer social functioning. Personality pathology is associated with greater prevalence, poorer recovery, and a higher likelihood of recurrence of depression in older adults. This study is a secondary analysis examining the relationships between personality traits associated with personality pathology (i.e. high neuroticism and low agreeableness), depression, and social functioning across older adults surveyed in primary care and psychiatric inpatient settings ($N = 227$). Individual variable as well as interaction models were examined. Higher neuroticism ($F_{[1,217]} = 40.119$, $p < .001$), lower agreeableness ($F_{[1,217]} = 20.614$, $p < .001$), and clinical status (i.e. primary care vs. psychiatric inpatient) ($F_{[1,217]} = 19.817$, $p < .001$) were associated with poorer social functioning. Clinical status moderated the relationships between neuroticism and social functioning ($B = -.0147$, $p = .0341$) and between agreeableness and social functioning ($B = .0268$, $p = .0015$). Interaction effects were not observed between neuroticism and depression or agreeableness and depression as they relate to social functioning. However, depression

severity was observed to mediate the relationship between neuroticism and social functioning [Indirect effect = .0212, 95% CI = .0141, .0289]. These findings highlight the importance of accounting for depression and clinical status in the assessment and treatment of older adults with personality pathology. Findings warrant future research focused upon mechanisms through which personality pathology and depression influence functional status in older adults.

MOBILE INTERVENTION OUTCOMES COMPARED PRE AND POST-SHELTER-IN-PLACE FOR MIDDLE AGED AND OLDER ADULTS

Chalise Carlson,¹ Ana Alfaro,¹ Christina Chick,² Martha Bruce,³ Valerie Forman Hoffman,⁴ and Christine Gould,¹ 1. *VA Palo Alto Health Care System, Palo Alto, California, United States*, 2. *Stanford University School of Medicine, Stanford University, California, United States*, 3. *The Dartmouth Institute, Geisel School of Medicine at Dartmouth, New Hampshire, United States*, 4. *Meru Health, Meru Health, California, United States*

The Meru Health Program (MHP), a mobile app-based intervention targeting depressive symptoms, teaches mindfulness and cognitive behavioral skills through video lessons and practices. MHP includes integrated asynchronous therapist and peer support. Our aim was to examine whether using the MHP reduced loneliness and improved mental health quality of life (QoL) in middle-aged and older adults with depressive symptoms (Patient Health Questionnaire-9 [PHQ-9] ≥ 7). The timing of this study partially overlapped with the emergence of the SARS-CoV-2 (COVID-19) pandemic resulting in California's shelter-in-place (SIP) orders. Fifty participants (42 enrolled prior to SIP) completed baseline assessments with a mean age of 57.06 (SD = 11.26; Range: 40-81 years) exhibiting mild to moderate depression symptoms (PHQ-9: $M = 12.28$, $SD = 5.47$). Participants enrolled pre-SIP exhibited significant improvements in QoL, $F(1,38) = 12.61$, $p = .001$, $\eta^2 = .25$, and significant declines in loneliness, $F(1,38) = 5.42$, $p = .03$, $\eta^2 = .13$. Improvements in QoL were found for post-SIP participants as well, $F(1,44) = 6.02$, $p = .02$, $\eta^2 = .12$. In contrast, loneliness did not improve for the post-SIP cohort, perhaps alluding to the increased impact of social isolation during SIP. Our findings indicate MHP can improve QoL symptoms before and during SIP. It is possible that middle-aged and older individuals may require more individualized support during SIP to help alleviate loneliness when social connection is severely restricted. MHP remains a promising and scalable solution for those middle-aged and older adults struggling with mental health symptoms.

OLDER ADULTS' EXPERIENCES IN AN ONLINE INTERVENTION FOR MANAGING SUBJECTIVE DEPRESSIVE SYMPTOMS

Janella Hudson,¹ Rachel Ungar,² Laurie Albright,³ Rifky Tkatch,⁴ James Schaeffer,² and Ellen Wicker,⁵ 1. *Optum/United Healthcare, Tampa, Florida, United States*, 2. *UnitedHealth Group, Minnetonka, Minnesota, United States*, 3. *UnitedHealth Group, Minneapolis, Minnesota, United States*, 4. *UnitedHealth Group, Oak Park, Michigan, United States*, 5. *AARP Services, Inc., Washington, District of Columbia, United States*

Background: Many older adults struggle with late-life depression, stress, and anxiety, especially when facing age-related transitions including retirement, relocation, and the death of a spouse. Given the consequences of depression among older adults, which include higher rates of suicide, timely interventions that help to manage depressive symptoms are essential. **Objective:** The primary purpose of this study was to explore the perceived efficacy of an online program in improving subjective depressive feelings. **Methods:** Older adult participants were recruited for semi-structured interviews ($n = 24$) in a web-based intervention that included interactive games and activities undergirded by a cognitive behavioral therapy (CBT) approach. Participants were asked to provide feedback about program features, including weekly module content, games, interactive activities and community interactions, and any perceived effects on their health behaviors and/or emotional well-being. Participants' responses were analyzed using qualitative content analysis. **Results:** Participants reported several gains, including developing the habit of forming ongoing, incremental goals, achieving wellness-related goals, and experiencing an overall positive shift in perspective. In addition, participants reported feeling greater gratitude, increased positivity, and improvement in mood. Featured games and activities helped to promote stress relief and entertainment, and mindfulness exercises were cited as the most helpful and/or enjoyable among participants. Participants expressed a preference for program content related to aging and aging-related transitions. **Conclusions:** This study demonstrated feasibility of an interactive web-based intervention for older adults with subjective depressive feelings, while also providing important findings about users' preferences for personalized, aging-related feedback.

PARENTING STRESS AND MENTAL HEALTH IN MIDLIFE ADULTS: EVALUATING THE ROLE OF GENDER

Jean Choi,¹ Elizabeth Munoz,² Robin Corley,³ Sally Wadsworth,³ and Chandra Reynolds,⁴ 1. *The University of Texas at Austin, Austin, Texas, United States*, 2. *The University of Texas at Austin, The University of Texas at Austin, Texas, United States*, 3. *University of Colorado Boulder, Boulder, Colorado, United States*, 4. *University of California Riverside, Riverside, California, United States*

Parenthood is a major source of stress in midlife that can have adverse consequences for long-term mental health trajectories. Yet, little research asks how parenting stress impacts mental health for both mothers and fathers in midlife. The current study examined (a) whether parenting stress was associated with parental depressive and anxiety symptoms and (b) whether these associations vary by gender. We utilized data from the ongoing Colorado Adoption/Twin Study of Lifespan behavioral development and cognitive aging (CATSLife); participants were aged 28 to 49 who reported having child(ren) ($N = 520$). Participants completed surveys that encompassed measures of demographics, relationships, health, and well-being. Overall, multilevel models accounting for non-independence among siblings and with relevant covariates (e.g., number of children, marital status) showed that higher levels of parenting stress were associated

with greater depressive ($b = .47 (.12)$, $p < .001$) and anxiety ($b = .27 (.09)$, $p < .05$) symptoms. An evaluation of the individual parenting stress items indicated that feeling less happy and more overwhelmed in the parental role were significantly associated with higher levels of anxiety and depressive symptoms. Parents who reported feeling less close to their children were also significantly more likely to report greater levels of depressive symptoms. These effects were consistent across mothers and fathers. Our study provides further insight into the negative associations between parenting stress and mental health among both mothers and fathers, and warrants further investigation into resources that may buffer these negative effects prior to late life.

PROTECTIVE EFFECTS OF PERCEIVED CONTROL ON PRESCRIPTION DRUG MISUSE 10-YEARS LATER IN THE MIDUS STUDY

Sara Miller, and David Almeida, *Pennsylvania State University, University Park, Pennsylvania, United States*

The current study examined if control beliefs predict prescription drug misuse (PDM) 10-years later and how problem drinking status moderates this relationship. PDM refers to taking medications without a prescription or in a manner not intended by the prescriber. Older adults are especially vulnerable to PDM due to drug sensitivity, comorbid health conditions, and high rates of polypharmacy. Participants were adults ($n=2162$, 56% female, mean age=54, range=30-84) who completed Waves 2 and 3 of the Midlife Development in the United States (MIDUS) study. At Wave 2, participants reported on two subscales of perceived control (personal mastery and constraints) and past 12-month problem drinking behaviors. At Wave 3, participants reported past 12-month PDM of five substances (painkillers, sedatives, stimulants, tranquilizers, and depression medications). Results indicated that at Wave 3, 10% of the sample reported misusing at least one prescription drug in the past year. Logistic Regression analysis revealed that problem drinking was associated with higher odds of PDM ($p < .001$), and perceived control was associated with lower odds of PDM ($p < .05$) after controlling for previous PDM and sociodemographic, health behavior, and health status covariates. However, there was an interaction effect such that perceived control was not protective for those individuals who engaged in problem drinking at Wave 2 ($p < .05$). Future analyses will explore the meaning of this interaction. Identifying psychosocial protective factors, such as perceived control, predicting PDM will be critical for designing interventions that prevent the adverse consequences of PDM among this population.

THE EFFECT OF COMPUTERIZED COGNITIVE TRAINING FOR ADULTS OVER 40 WITH DEMENTIA-RELATED ANXIETY

Jennifer Roberts,¹ and Molly Maxfield,² 1. *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*, 2. *Arizona State University, Phoenix, Arizona, United States*

Dementia-related anxiety (DRA) may occur when cognitive lapses are appraised as threatening. Individuals with DRA may seek activities to improve cognitive function, including popular computerized cognitive training programs like Lumosity®. We evaluated if DRA changed after eight

weeks of Lumosity© use and whether changes were maintained over time. Participants aged 40 and older with pre-existing DRA participated via Amazon's Mechanical Turk (T1 N = 395; age M = 52.49, SD = 8.71) and were randomly assigned to the experimental (Lumosity© software), active control (Lumosity© crossword puzzles), or no treatment group. Participants completed measures of DRA at T1 and at four follow-up points (T2 = 8 weeks; T3 = 12 weeks; T4 = 16 weeks; T5 = 20 weeks). Repeated measures ANOVAs were used to evaluate the change in DRA. A significant T1-T2 reduction in DRA occurred for the Lumosity© group only ($p = .01$, partial- $\eta^2 = .03$). Longitudinal changes were observed for the Lumosity© group only: DRA scores at T1 were significantly greater than at T2, T4, and T5 ($ps < .05$). A step-up test procedure was conducted to determine minimum treatment dose effects. A greater reduction in DRA occurred between the Lumosity© and crossword puzzle groups between 25.00 and 29.99 hours of software use ($p = .05$, partial- $\eta^2 = .19$). Lumosity© software outperformed crossword puzzles in DRA reduction from T1 to T2, which was maintained for 12 weeks post-software use. Independent of Lumosity's intended purpose of supporting cognitive functioning, participants subjectively believe it helps and experience associated benefits.

THE ILLNESS EXPERIENCE OF VETERANS WITH DEMENTIA: PERCEIVED MEASURES RELATED TO DEPRESSIVE SYMPTOMS

Amanda MacNeil,¹ Katherine Judge,² Kate McCarthy,³ and David Bass,⁴ 1. *Cleveland State University, Fairview Park, Ohio, United States*, 2. *Cleveland State University, Cleveland, Ohio, United States*, 3. *Benjamin Rose Institute on Aging, Benjamin Rose Institute on Aging, Ohio, United States*, 4. *Benjamin Rose Institute on Aging, Cleveland, Ohio, United States*

Recent work has examined how individuals with dementia (IWDs) experience their illness, although few studies have looked at IWDs who report heightened depressive symptoms, a key well-being outcome. Stressing the ability of IWDs to self-report and guided by the Stress Process Model for Individuals with Dementia, this study examined the relationships between depressive symptoms and various aspects of the illness experience including objective cognition, perceived memory difficulty, perceived functional difficulty, and dyadic relationship strain. The sample includes IWDs with mild to severe dementia who are veterans (N=69). Significant positive correlations emerged between depressive symptoms and several measures of the illness experience: perceived cognition ($r=.48$, $p<.001$), perceived function ($r=.43$, $p<.001$), and dyadic relationship strain ($r=.32$, $p=.01$). In contrast, objective cognition, measured by a modified version of the Blessed Orientation Memory Concentration test, was not significant ($r=-.06$, $p=.63$). A multiple regression found the total variance explained by all independent variables was 32% ($R^2=.32$, $F(4,68)=7.58$, $p<.001$), with perceived memory difficulty ($B=.26$, $p<.01$) and dyadic relationship strain ($B=.25$, $p=.04$) accounting for unique and significant variance in depressive symptoms. A mediation analysis indicated perceived memory difficulty fully mediated the relationship between perceived functional difficulty and depressive symptoms. Findings highlight the importance of IWDs perceptions of

their illness experience for psychosocial well-being outcomes, such as depressive symptoms. Findings add to the literature by showing the importance of IWDs perceptions of their illness and their impact on well-being outcomes. Results also demonstrate the utility and feasibility of including self-reported data from IWDs in research studies.

THE LONG-TERM IMPACT OF CHILDHOOD DISABILITY ON MENTAL HEALTH IN MID- TO LATE-ADULTHOOD

Jessica West, *Duke University Aging Center, Durham, North Carolina, United States*

For decades, life course and stress process scholars have documented that negative, stressful experiences in childhood have consequences for health across the life course. One aspect of the childhood adversity that deserves more research attention is childhood disability. Children with disabilities experience higher levels of psychological distress compared to their peers and having a disability can negatively impact traditional markers of the transition to adulthood (e.g., education, employment, family status). At present, there is limited evidence regarding the impact of childhood disability on mental health over multiple years of adulthood. This study applies random effects models to nationally representative data from five waves (2008-2016) of the Health and Retirement Study (n=15,380; n=590 with a childhood disability), to examine how experiencing disability before the age of 16 shapes depressive symptoms over multiple years of adulthood. Given known gender differences in mental health, the models are stratified by gender to examine how the association between childhood disability and adult mental health varies by gender. Preliminary results suggest that experiencing a childhood disability is associated with different patterns of depressive symptoms in adulthood. Men who experienced childhood disability report more depressive symptoms in adulthood, net of sociodemographic, adult health, and childhood disadvantage covariates. Women who experienced childhood disability report more depressive symptoms in adulthood, net of all covariates except for childhood depression. Next steps are to conduct age-based growth curve models using Stata's mixed function to estimate whether childhood disability influences baseline and growth of depressive symptoms in adulthood.

TIME USE, GENDER, AND MENTAL HEALTH OF OLDER ADULTS IN RURAL CHINA

Zhiyong Lin,¹ and Feinian Chen,² 1. *The University of Texas at Austin, Austin, Texas, United States*, 2. *University of Maryland College Park, University of Maryland, Maryland, United States*

Time use is considered a valuable descriptor of people's lifestyles, and studying how people spend their time is critical for understanding the determinants and consequences of individual well-being. In this study, we first develop a time use typology to characterize how older adults in rural Chinese families allocate their time in later life, and then examined how older adults' time allocation influenced their mental health, with a special focus on differential implications for older women and men. Data derived from 2015 and 2018 waves of a longitudinal study of 1,007 older adults, aged 60 and older, living in rural areas of Anhui Province, China. We

specifically focused on how social and solitary dimensions of time use, as well as time spent within and outside households, impacted depressive symptoms of older adults. Using the K-means cluster analysis, we identified four time use categories: “work-oriented,” “socially-active,” “homemaker/caretaker,” and “socially-isolated.” Results from fixed-effects regression analysis demonstrated that older women involved in “socially-active” time-use category tended to report better mental than those in other time-use types, while the time spent on housework and caregiving was harmful to their mental health. For older men, more time spent on paid activities outside households (“work-oriented”) was associated with better psychological outcomes while solitary leisure time (“socially-isolated”) was associated with higher levels of depressive symptoms. These findings will be helpful for health policymakers and practitioners who seek to better identify vulnerable subpopulations and to design effective intervention strategies to reduce mental health problems.

Mental Health (Health Poster)

DENTAL ISSUES AND DEPRESSIVE SYMPTOMS IN INSTITUTIONALIZED OLDER ADULTS

Alexandre Bulgarelli,¹ Luiza Guilhermina Lopes,² Karla Frichembruder,² and Camila Santos,³ 1. *Federal University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil*, 2. *University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil*, 3. *Federal University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil*

Objective: To map and discuss scientific knowledge involving the research object "Oral health conditions and depression in institutionalized elderly people". Method: Systematic scoping review. The mapping of the selected data was carried out using Summative Content Analysis from Manifest Themes' perspective in the texts. After the exclusions, 27 articles were selected. Results: With the analysis of the articles, it was possible to divide them into two themes named: 'Oral health condition: Long-term institution, depressive disorders and pluralities' and 'Depression in institutionalized older adults: medicalization, oral health conditions and subjectivities'. Heterogeneity was found in the sub-themes of the articles accessed and in the characteristics of the published studies as well. All continents have publications on the topic. Many studies with deductive methods have been carried out when dealing with its methodology, and less research has been carried out with inductive methods. Conclusion: The present study identified that there is an association between some oral health conditions (dry mouth and tooth loss) and prevalence of depressive disorders in institutionalized older people. The knowledge produced about oral health and mental health in long-term care facilities for the elderly is relatively recent, reflecting the contemporary nature of the theme. Besides, the construction of this knowledge is associated with the diversity of epidemiological and qualitative studies seeking to answer questions that involve technical and subjective plurality involving mental health and oral health of institutionalized older adults.

EFFECTS OF PARTICIPATING IN A VOLUNTEER DRIVING PROGRAM ON MENTAL HEALTH IN SERVICE RECIPIENTS AND VOLUNTEERS

Machiko Tomita,¹ and Sutanuka Bhattacharjya,² 1. *University at Buffalo, State University of New York, Buffalo, New York, United States*, 2. *Georgia State University, Atlanta, Georgia, United States*

Objectives: To assess the effects of a volunteer transportation program on mental health in riders and volunteers. Methods: A cross-sectional study (N=133, age ≥60) compared pre- and existing (≥2 years) riders, pre- and existing (≥2 years) volunteer drivers, and riders (Rs) and pre-volunteers (PreVs), representing general older adults. The cohorts belonged to a large, community volunteer organization. Outcome measures, depression and quality of life, were analyzed using ANCOVA. Percentages of people who wanted to go to specific destinations with available transportation were identified for pre-riders (PreRs) and Rs. Results: Rs had better depression scores (p<.001), no longer exhibited depressive symptoms (p=.005), and were better in quality of life (p=.002) than PreRs. Rs were similar to PreVs. PreRs' major needs were going to medically related places (doctors' offices – 74.4%, drug stores - 44.2%, hospitals – 37.2%) and basic living (grocery – 60.5%, clothing -37.2%). In Rs, these had significantly lowered, but still 40% wanted to go to doctors' offices and 30%, grocery stores. Volunteer driver's (Vs)' depression (p=.009), health (p=.006), and social relationships (p=.004) were significantly better than PreVs'. Discussion: Although the use of free transportation up to four times a month may not be enough to improve perceived health for Rs, it was beneficial to prevent depression and increase quality of life. Since many PreVs were doing volunteer work other than driving, the type of volunteer work matters. Regularly helping people, in person, with their core needs for living resulted in positive outcomes for Vs.

GROUP-BASED SMOKING CESSATION PROGRAM FOR OLDER ADULTS WITH SERIOUS MENTAL ILLNESS

Heather Leutwyler,¹ and Erin Hubbard,² 1. *University of California, San Francisco, San Francisco, California, United States*, 2. *UCSF, UCSF, California, United States*

Smoking is one of the most important modifiable risk factors for excess morbidity and mortality in older adults with serious mental illness (SMI). Many older smokers with SMI are reportedly motivated to quit, however evidence-based treatment targeting this vulnerable group is limited. To address an urgent need to identify interventions that assist smoking cessation efforts, we are conducting a pilot two-arm randomized controlled trial (RCT) targeting adults with SMI. Our Videogame-based Physical activity (“VIP”) smoking cessation intervention includes: a) group videogame-based physical activity intervention (50 minutes, 3X/week for 12 weeks), b) pharmacotherapy (bupropion or nicotine replacement therapy), and c) smoking cessation counseling. Upon completion of the 12 week program, participants in the VIP and control groups completed a semi-structured interview in order to determine how the program impacted their smoking cessation. To date, six participants completed an interview. Participants described how the program helped with smoking cessation because it allowed them to “face their addiction”

and learn more about why they smoke and how to quit. The program provided the structure, resources, and encouragement needed to start the process of quitting. Finally, they enjoyed having the game time as a distraction from smoking. Older adults with SMI need support, resources, and group-based exercise as they begin quitting and practice the skills needed to quit.

INCREASING MIXED-BERRY FLAVONOID INTAKE MAY REDUCE DEPRESSIVE SYMPTOMS IN OLDER ADULTS: FRAMINGHAM HEART STUDY

Courtney Millar,¹ Alyssa Dufour,² Marian Hannan,¹ and Shivani Sahni,¹ 1. *Hebrew SeniorLife, Roslindale, Massachusetts, United States*, 2. *Hebrew SeniorLife, Boston, Massachusetts, United States*

Depression affects more than 250 million people worldwide. Although epidemiological studies have linked higher dietary flavonoids with depression prevention in older women, it is unknown if increasing dietary flavonoids could effectively reduce depression. Mixed berries (blueberry, blackberry, and raspberry) are a rich source of flavonoids, particularly anthocyanin, flavanol, and flavan-3-ol subclasses. Our aim was to determine the association of mixed-berry flavonoid intake with change in depressive symptoms over ~8 years in older adults from the Framingham Heart Study. This community-based prospective longitudinal study included 1,278 adults with assessments on diet (food frequency questionnaire) and depressive symptoms (Center for Epidemiologic Studies Depression, CES-D) at baseline (1998-2001) and follow-up (2005-2008). Absolute change in mixed-berry flavonoid intake (defined as sum of anthocyanin, flavanol, and flavan-3-ols, mg/day) and change in CES-D scores were calculated. Linear regression estimated beta and standard error (SE) for change in CES-D scores per 250 mg/day increase in mixed-berry flavonoids (obtained from ~3/4 cup of mixed berries), adjusting for baseline age, sex, energy-intake, current smoking, body mass index, physical activity, cardiovascular disease, and non-melanoma cancer. Mean age was 59±9 years (range: 33-81), 57% female and mean change in mixed-berry flavonoid intake was 15.0±72.8 mg/day over ~8 years. In adjusted models, each 250 mg/day increase in mixed-berry flavonoid intake was associated with a 1-point reduction in depressive symptoms (beta: -1.06, SE: 0.61, p=0.08) over ~8 years, although this was not statistically significant. These data highlight the need for randomized clinical trials of flavonoid-rich berries to target depressive symptoms in older adults.

MINIMALLY ADEQUATE MENTAL HEALTH TREATMENT AND MORTALITY IN PRIMARY CARE OLDER ADULTS WITH DEPRESSION AND ANXIETY

Helen-Maria Vasiliadis,¹ Catherine Lamoureux-Lamarche,¹ Sébastien Grenier,² and Pasquale Roberge,¹ 1. *Université de Sherbrooke, Université de Sherbrooke, Quebec, Canada*, 2. *Université de Montréal, Institut universitaire de gériatrie de Montréal, Quebec, Canada*

Receipt of quality mental health (MH) care can influence mortality. Given the scarce literature on the topic, the aim was to assess the 3-year risk of mortality in older adults (OA) associated with receiving adequate MH treatment for depression/anxiety in an epidemiologic context. The study sample included 358 OA with depression/anxiety recruited

in primary care practices and followed prospectively for 3 years. Mortality was assessed from vital statistics data. Adequate care was based on receipt of pharmacotherapy, follow-up care and psychotherapy. Propensity score analysis was carried out where the inverse probability (IPW) of receiving adequate treatment was calculated. Time to event analyses with IPW was used to assess the effect of receipt of adequate MH treatment on the risk of mortality controlling for individual and health system factors. The results showed that receipt of adequate MH treatment reduced the risk of mortality (HR0.44; 95% CI: 0.22 – 0.99). Individual factors that increased mortality were male sex, being single, reduced functional status and cognitive functioning, # physical disorders, current smoking; while exercise reduced risk. Health system factors such as past # of hospitalizations increased the risk; while # of emergency department visits and continuity of care reduced mortality. Finally, treating depression/anxiety with minimal follow-up care and pharmacotherapy or psychotherapy has a significant impact on reducing mortality in OA. Primary care physicians should recognize the important potential impact of years of lives saved when providing quality MH care to OA.

SLEEP HEALTH, DEPRESSION, PAIN AND QUALITY OF LIFE AMONG OLDER ADULTS DURING THE FIRST MONTHS OF THE COVID-19 PANDEMIC

Rebecca Lorenz,¹ Devita Stallings,² Janice Palmer,³ and Helen Lach,⁴ 1. *University at Buffalo, Buffalo, New York, United States*, 2. *Saint Louis University, St. Louis, Missouri, United States*, 3. *Webster University, St. Louis, Missouri, United States*, 4. *Saint Louis University, Saint Louis, Missouri, United States*

To slow the spread of Covid-19, many states instituted restrictions on group size for religious services, exercise, and social engagement. We are beginning to understand the effect of these mandates on older adults. The purpose of this study was to examine the relationships between sleep health, depression, pain, and quality of life (QOL) among older adults during the initial months of the Covid-19 pandemic. Older adults completed an anonymous online survey to collect data including personal characteristics, behaviors, and health conditions during May-September 2020. Sleep Health was assessed with a survey of satisfaction, timing, efficiency, and duration of sleep along with daytime alertness. Pearson correlations were used to explore relationships between age, education, socioeconomic status, pain, depression, and QOL. Participants (N=509) were primarily female (n=392, 77%), white (n=466; 92%), college educated (n=471, 93%) and with a mean age of 75.6 years (SD=5.0; range 63-93 years). Mean Sleep Health score was 7.4 (SD=2.1; range 0-10). Higher (better) Sleep Health scores were associated with education (r=.15, p<.01) and socioeconomic status (r=.17, p<.01) and lower scores with depression (r= -.35, p<.01), pain (r= -.23, p<.01), and QOL (r= -.26, p<.01). Poorer Sleep Health among older adults during the initial months of the pandemic were associated with depression, pain, and reduced QOL. Sleep, depression, and pain have reciprocal relationships that may have lasting consequences on physical and mental health among older adults. These findings suggest that poor sleep health should be identified and treated to improve QOL among older adults.

Mental Health and Technology

CONNECTING OLDER ADULTS WITH MENTAL HEALTH APPS: A SURVEY OF PROVIDER APP AND EDUCATION MATERIAL USE

Priyanka Mehta,¹ Chalise Carlson,² Jason Anderson,² Ana Alfaro,² Erin Sakai,² and Christine Gould,² 1. VA Palo Alto Health Care System, Palo Alto, California, United States, 2. VA Palo Alto Health Care System, Palo Alto, California, United States

Many older veterans have access to mobile devices and are interested in using apps for mental health self-management, but few have ever downloaded health apps. To address the need for awareness of and access to VA mental health apps, we developed patient educational materials aimed towards older (or novice) users of mobile devices. The present study explored health care providers' and staff's perceptions about use of mental health mobile applications (apps) with older veterans and examined potential utility of these patient educational materials. Requestors of mobile device education materials (N = 90) were surveyed when ordering materials and again 4 months later. Baseline and follow-up surveys assessed frequency of app recommendation, and comfort recommending apps. Baseline surveys examined perceived advantages of apps; follow-up surveys examined perceived utility of the educational materials. Descriptive statistics and qualitative analysis were conducted. Most requestors (68.5%) initially were not comfortable using apps, yet perceived many advantages to using apps and hoped materials could facilitate app use. At follow-up, requestors felt more comfortable recommending apps alongside our materials. Qualitative analysis revealed perceived advantages to using the education materials. The benefits of developing and disseminating educational materials for providers to share with older veterans helped support older veterans' app use, and potentially increased providers' comfort with and frequency of recommending apps to their older patients. Access to educational materials can mitigate discomfort among providers in recommending apps to older users and may bring about valuable discussions about apps which support mental health.

EMENTAL HEALTH LITERACY AND PSYCHOLOGICAL DISTRESS AS PREDICTORS OF BARRIERS TO MENTAL HEALTH SERVICES

Eve Root,¹ and Grace Caskie,² 1. Lehigh University, Philadelphia, Pennsylvania, United States, 2. Lehigh University, Bethlehem, Pennsylvania, United States

Since the COVID-19 pandemic, psychologists have begun to rely heavily on technology to provide mental health information and services (APA, 2020). As the older adult population increases, the number of older adults in need of mental health services also increases; however, little is known about the way older adults might utilize technology to inform mental health-related decisions. This study expands on the construct of eHealth Literacy by examining eMental Health Literacy, which is defined as the degree to which individuals seek, find, understand, and appraise basic mental health information and services online that are needed to

inform mental health-related decisions. A sample of 244 older adults (M=68.34, range=65-82 years) were recruited online through Amazon Mechanical Turk. A structural equation model was estimated specifying eMental Health Literacy and psychological distress as predictors of extrinsic and intrinsic barriers to mental health services. After adding three correlated errors, the model achieved good fit ($\chi^2(110)=329.20$, $p<.001$, SRMR=.08, CFI=.93, TLI=.91, GFI=.86, RMSEA=.09). All indicators were significantly related to their latent construct ($p<.001$). The results indicated that, controlling for psychological distress, higher eMental health literacy was significantly related to fewer reported intrinsic ($b=-.386$, $p<.001$) and extrinsic barriers ($b=-.315$, $p<.001$) to mental health services. Higher distress was also significantly related to more intrinsic ($b=.537$, $p<.001$) and extrinsic barriers ($b=.645$, $p<.001$) to mental health services. These findings suggest that, as we move towards a more digital world, eMental health literacy could play a significant role in the way older adults navigate through the mental healthcare system.

MOOD LIFTERS: A PEER-LED MENTAL HEALTH PROGRAM FOR OLDER ADULTS VIA VIDEO CONFERENCING

Courtney Funk,¹ Rebecca Ferber,² Anne Harrington,³ Jennifer Porte,⁴ Cathleen Connell,¹ Susan Maixner,² and Scott Roberts,² 1. University of Michigan School of Public Health, Ann Arbor, Michigan, United States, 2. University of Michigan, Ann Arbor, Michigan, United States, 3. The University of Michigan, ANN ARBOR, Michigan, United States, 4. Mood Lifters, LLC, Ann Arbor, Michigan, United States

Effective and scalable mental health programs are greatly needed for older adults, given the vast majority in need do not receive formal mental health services. In this study, we adapted Mood Lifters—a peer-led, community-based program promoting mental well-being—to address the unique needs of older adults. The 14 weekly program sessions were delivered via Zoom. Twelve older adults (mean age = 69.7 years; 4 men, 8 women) enrolled; 9 completed the program (2 of 3 dropouts were due to health issues). A battery of validated measures administered within one week before and after the program assessed domains including depression and anxiety, stress management, and health behaviors. Compared to baseline, participants who completed the program showed significant improvements in perceived stress ($p=0.03$), sleep quality ($p=0.02$), and emotion regulation via cognitive reappraisal ($p=0.06$). Depression and anxiety symptoms (assessed by the Geriatric Depression and Anxiety Scales, respectively) were lower at program completion, although improvements were not statistically significant. No significant changes from pre- to post-test were reported in loneliness and health behaviors. Participant ratings of program satisfaction were very high (mean = 4.78/5, with 1=poor, 5=excellent). Results from this pilot test of Mood Lifters for Seniors suggest it is feasible and acceptable for outreach to older adults, with preliminary evidence of benefits in several domains related to mental health and wellness. Future randomized trials with larger, more diverse samples will be necessary to confirm program benefits.

PILOTING AN AUGMENTED REALITY LIFE REVIEW EXPERIENCE TO PROMOTE MENTAL HEALTH OUTCOMES IN AGING ASIAN AMERICAN WOMEN

Sarah Hwang,¹ Jazlyn Armendariz,¹ Jeremy Argueta,¹ Veronica Fruith,² and Thomas Chan,¹ 1. *California State University Northridge, Northridge, California, United States*, 2. *Dominican University of California, Dominican University of California, California, United States*

Asian-American older women report the highest prevalence of suicidal ideations and rates of completed suicide compared to other racial groups. Ironically, Asian-American communities report disproportionately low rates of formal mental health utilization—this may be attributed to the lack of culturally-relevant services and negatively ingrained perceptions of mental health aid. One potential solution that has not been widely investigated is the use of technology to help older Asian-American women engage in mental health interventions. This study leverages innovations in augmented reality (AR) technology (i.e., overlaying of digital holograms onto the real world) to create a life review intervention aimed at promoting mental health well-being. The application, Tell-Being, is a personalized holographic life review experience that facilitates older adults to foster a sense of coherence and wholeness within their lives. Pilot data collection was amassed from four aging Asian-American female participants averaging 51.3 (SD=8.61) years of age. Initial pre/post analyses showcased mean differences that trend towards a higher presence of emotion regulation from pre-test (M=4.88, SD=1.08) to post-test (M=5.21, SD=1.17). Although data collection was prematurely halted due to COVID-19, results trended in promising directions. The technological innovations and findings from this study may lead to promising novel avenues to address barriers for older Asian-American women in seeking mental health assessment and treatment in a “new normal” world.

TECHNOLOGY BASED COGNITIVE BEHAVIORAL THERAPY ON PSYCHOLOGICAL DISTRESS: EXPLORING HEALTH, PAIN, AND ACTIVITY

Avani Shah,¹ Martin Morthland,² and Forrest Scogin,² 1. *University of Alabama, Tuscaloosa, Alabama, United States*, 2. *University of Alabama, University of Alabama, Alabama, United States*

This randomized controlled trial investigates two technologically based self-administered cognitive behavioral depression treatments (CBT) on psychological distress in older adults. Health may change the ability to participate in types of activities, thereby impacting mental well-being and treatment response. The aims of this research are 1) to understand the impact of technologically based cognitive behavioral treatment on psychological distress 2) explore how health, pain, and activity engagement may affect treatment response. Fifty one participants recruited were randomized to one of 3 groups: audio-based cognitive behavioral therapy, computer-based cognitive-behavioral therapy, and control group. The combined treatment groups are compared to the control group. Health was examined in multiple ways; the Vulnerable Elders Scale-13 score ; (Saliba et al., 2001); and a reported chronic pain condition. For overall psychological distress, improvement on the Brief Symptom Inventory General Severity Index (GSI; Derogatis & Spencer,

1983) scores from baseline to post-treatment indicated treatment response. The California Older Person's Pleasant Events Scale (COPPE; Rider, Gallagher-Thompson, & Thompson, 2004) measured activity engagement. While controlling for the Time 1 GSI score, an ANOVA revealed a significant difference in psychological distress between the CBT treatment group and control group $F(1, 43) = 4.22, p = .046$. A linear regression analysis with the VES-13 score and GSI baseline score as predictors and the GSI posttreatment score as the dependent variable, found that health did not significantly predict psychological distress outcomes. Observation of the descriptives and these analyses suggest that CBT can impact psychological distress, potentially even with variations in health and pain.

Session 9375 (Poster)

Mental Health, Social Connection, and Isolation

DOG PARK MEMBERSHIP AND LIFE SATISFACTION AMONG OLDER ADULTS

Betz King,¹ Adam Duberstein,² and McGlenn Maureen,³ 1. *King & Associates, King & Associates, Michigan, United States*, 2. *King & Associates, Hazel Park, Michigan, United States*, 3. *Southfield Mental Health, Southfield, Michigan, United States*

Dog park members initially join and attend dog parks for the wellbeing of their dogs, but often experience their own biopsychosocial benefits. This mixed methodology (Quantitative n=44, Qualitative n=11) pilot study utilized qualitative heuristic interviewing (Moustakas, C., 1990) and the Satisfaction with Life Survey (Pavot, W., & Diener, E. 2013). Data gathered from interviews and surveys administered to participants of a members-only dog-park indicate a high satisfaction with life. Members 60 years and older reported feelings of life satisfaction almost 7 points over the total respondent average, placing them in the “highly satisfied” range. All members experience the dog-park as a supportive social environment that benefits their physical health, mental health and the well-being of their canine companions. Five qualitative themes were identified: Canine Well-being, Community, Mental Health Benefits, Physical Health Benefits and Fights, Falls & Frustrations. These findings demonstrate the need for more research into the impact and importance of pet ownership, community dog parks and outdoor green spaces on older adults and life satisfaction.

FOSTERING INTERGENERATIONAL CONNECTIONS IN THE TIME OF COVID-19: A FRIENDLY CALLER PROGRAM

Maria Claver,¹ Tatia Clark,² Alexandra Wilkinson,³ and Chan Park,⁴ 1. *California State University, Long Beach, Whittier, California, United States*, 2. *California State University Long Beach, California State University, Long Beach, California, United States*, 3. *California State University, Long Beach, California State Univ Long Beach, California, United States*, 4. *Covia - Lutheran Towers, Long Beach, California, United States*

Social isolation affects one in five older adults, significantly increases the risk of premature death from all causes and is associated with higher rates of depression, anxiety and suicide. Covid-19 has exacerbated social isolation, including among older adults that reside in senior apartments. In response, a Friendly Caller Program was developed to foster intergenerational social connections among university students and residents in a large housing community that serves older adults aged 62 and older who have limited income and have mobility impairments. This study aimed to evaluate the Friendly Caller Program from the perspective of the older adult. An online survey includes questions about the participants' demographic characteristics, physical and mental health self-assessment, social support, and ways in which the Friendly Caller Program has affected these areas of their life. An open-ended question assesses older adult participant expectations of the Friendly Caller Program. Results describe the population currently being served by this program and indicate that the program has a positive influence on participants' feelings of safety, support and ability to function. Suggestions for future research include assessing university student perceptions about the benefits of participation as callers in the program and creating a toolkit that can guide other universities to create similar programs in partnership with housing communities that serve older adults.

SAVING FALL-INJURED OLDER ADULTS FROM DEPRESSIVE SYMPTOMS: THE MEDIATING ROLE OF SOCIAL PARTICIPATION

Yalu Zhang, Lei Zhang, Jiling Sun, Xinhui Zhang, Jingjing Sun, Xinming Song, and Gong Chen, *Peking University, Beijing, China (People's Republic)*

Falls are the second primary cause of unintentional injury deaths globally. Prior studies found that fall incidences are associated with depressive symptoms among older adults, which could reversely lead to repeated fall incidences. However, few have investigated the role of social interventions in saving fall-injured older adults from experiencing depressive symptoms among older adults. Using the Chinese Health and Retirement Longitudinal Study (CHARLS) 2011-2018 data and multiple levels of fixed-effect analysis, this study examined the potential mediating role of social participation in alternating the effect of fall injuries on depressive symptoms. For the first time, this study specified the fall-injured older adults among those who had fall incidences. It also implemented the current literature by removing the bias caused by unobservable confounding variables at provincial and city levels. The descriptive results show that 22.2% and 20.6% of rural ($n=4,972$) and urban ($n=3,258$) older adults (65+), respectively, experienced fall incidences, among whom 45.1% needed one or more times of medical treatment. The fixed-effect results show that for urban older adults, social participation accounted for partial effects (17.2%) of fall injuries on their depressive symptoms. For rural older adults, fall injuries are significantly associated with more depressive symptoms, but social participation no longer functions as the mediator. Findings from this study emphasize the necessity of collecting efforts from multiple levels to improve the social engagement of urban older adults who had fall injuries. Future studies could further specify what types of social participation would be more helpful in buffering the intervention effects.

TECHNOLOGY ACCEPTANCE AND DEPRESSIVE SYMPTOMS AMONG COMMUNITY-DWELLING OLDER PEOPLE

Suk-Young Kang,¹ Jeungkun Kim,² Jeffrey Winthal,³ and Rosemarie Lenz,³ 1. *Binghamton University, State University of New York, Binghamton, New York, United States*, 2. *Kangnam University, Yong-In, Kyonggi-do, Republic of Korea*, 3. *Binghamton University, Binghamton, New York, United States*

Depression is a major public health issue among older adults, with an estimated prevalence between 5% and 10%. The aim of this study is to explore the possible benefits technology acceptance has in reducing depression among older people. Mail-survey data were collected from community-dwelling adults over the age of 65. This method was chosen over face-to-face surveys due to Covid-19. There were 192 total participants. The GDS-5 was used to measure the level of depressive symptoms. Among the participants, 25 participants (13%) scored higher than 2, indicating the presence of depression. Using a hierarchical regression analysis revealed that the equation explained 42.4% of the variance (adjusted R square = .382) in levels of depression ($F(3,176) = 9.973$, $p < .000$). Variance inflation factor (VIF) values were smaller than 10, indicating that multicollinearity among the correlates was not an issue. The correlates of the level of depression were: level of education, overall physical health, level of loneliness, perceived ease of technology use, attitude toward technology use, and intent to purchase new technology for older people. Results indicate that a positive attitude toward technology use might be inversely associated with depression levels. This shows how quality of life related to mental health may be improved by a change in attitude in favor of technology use. Participants were interested in learning to use new technology, and would like more opportunities to do so. Policy changes that increase lifelong learning options would help to make this happen.

THE IMPACT OF ORAL HEALTH ON PSYCHOLOGICAL DISTRESS AMONG OLDER ADULTS IN CALIFORNIA

Esmeralda Melgoza,¹ Jennifer Archuleta,¹ Emma Tran,² Gabino Abarca,² and Anna Fiastro,³ 1. *UCLA Fielding School of Public Health, Los Angeles, California, United States*, 2. *UCLA, UCLA, Los Angeles, California, United States*, 3. *University of California, Los Angeles, Los Angeles, California, United States*

In California, the population of adults ages 65 and older is projected to increase from 11% in 2010 to 19% in 2030. The aging of the population requires modifications in public health to ensure that people are not only living longer, but also healthier lives. Oral health is an important, but often overlooked factor that affects the overall health of older adults. Poor oral health increases the risk of physical comorbidities, decreases chewing performance, limits food choices, and exacerbates weight loss. Furthermore, poor oral health disrupts social health via decreases in verbal communication and facial expressions, such as smiling. This study examines the effects of oral health, assessed by tooth condition, on psychological distress among adults ages 65 and older in California. The study uses the 2019 California Health Interview Survey (CHIS), an annual survey of a representative sample of the state's residential, noninstitutionalized population. Logistic regression models are used to determine

the association between tooth condition on psychological distress controlling for gender, race, and elderly poverty index. Worsening tooth condition increases the odds of having psychological distress with lower odds among individuals 85+, and higher odds among women, and non-Hispanic whites compared to Hispanics. Public health programs and interventions are required in California to prevent and mitigate the impacts of poor oral health on psychological distress among the increasing and diverse older adult population.

THE INTERPLAY BETWEEN RETIREMENT TRANSITION SEQUENCES AND MENTAL HEALTH: FOCUSING ON GENDER DIFFERENCES

Oejin Shin,¹ Sojung Park,² and BoRin Kim,³ 1. *University of Illinois at Urbana Champaign, Savoy, Illinois, United States*, 2. *Washington university, St.Louis, Missouri, United States*, 3. *University of New Hampshire, University of New Hampshire, New Hampshire, United States*

Although retirement has been given a substantial amount of attention, there are gaps in the literature on 1) the various forms of retirement (nature= voluntary/involuntary, timing= early/ late, type= full/ partial) using with previous employment history, and 2) gender differences in retirement transition. Drawing on the life course perspective, this study examined the gender differences in retirement transition sequences using the labor participation history and various forms of retirement. Data are from the 2004 to 2016 HRS with 1,653 older workers. Sequence analysis was used to answer how individuals experienced retirement in the extended time frame. OLS regression analysis was used to estimate the relationship between retirement transition sequences and depression. For both genders, eight clusters of retirement transition sequences were identified. However, the most prevalent group for males was those who experience voluntary retirement transition from full-time work in mid-time point (19%), while the most prevalent group was a gradual involuntary retirement (21%) for females. Regarding the association with depression, those who experienced voluntary retirement after full-time work in all different time points (early, mid, late) and those who retired from self-employment were less likely to have depressive symptoms for males. For females, only those who experienced voluntary retirement from full-time work in mid-time point were less likely to have depressive symptoms. This result contributes to identifying the heterogeneity of retirement transition sequences and their association with depression. The result suggests important implications of gender-specified intervention programs to prevent involuntary retirement and mental health support program for involuntary retirees.

Session 9380 (Poster)

Minority and Diverse Populations: Between-Group Differences and Within-Group Experiences

BMI CHANGE AFTER PARENT'S DEATH IN ADULTHOOD: EXAMINING AGE AND RACE DIFFERENCES WITH TIME-VARYING EFFECTS MODELING

Hye Won Chai, Hyungmin Cha, and Debra Umberson, *The University of Texas at Austin, Austin, Texas, United States*

Parental bereavement in adulthood is a stressful event that can have adverse health consequences for middle and older adults, including weight gain. Considering that the impact of bereavement is found to vary depending on the timing of death as well as across race/ethnicity, changes in weight after a parent's passing may also be contingent on the timing of parent's death and the bereaved individual's race/ethnicity. Using Time-Varying Effects Modeling (TVEM), this study examined whether changes in BMI following a parent's death differed across respondent's age when their parent passed away. We also tested whether these age differences varied by race. Data came the Health and Retirement Study (HRS) Waves 1 – 13 and we selected respondents who experienced passing of either parent while participating in HRS. Analyses were run separately for mother's death (n = 6,191) and father's death (n = 3,301). Results showed significant racial/ethnic differences in BMI change following a mother's death, particularly during late midlife to early late life. Specifically, non-Hispanic White and Black adults showed a greater increase in BMI compared to Hispanic adults. These race differences were consistent for father's death as well, but to a lesser extent compared to mother's death. Results suggest that White and Black adults who lost their parents between late midlife and early late life gained more weight compared to their Hispanic counterparts. This may be attributed to the racial/ethnic differences in health behaviors in response to parent's death.

CARING FOR THE STONEWALL GENERATION: ASSESSMENT OF STAFF TRAINING FOR TRANSGENDER PERSONS LIVING IN LONG TERM CARE

Sara English, *University of South Carolina, Blair, South Carolina, United States*

Transgender persons who came of age in the late 1960s are considered LGBTQ+ elders - The Stonewall Generation. These persons experience unique bio-psychosocial challenges, often complicated by a history of a lack of access to good medical care and social supports. Discrimination and bias can influence the provision of care and the protection of privacy for transgender or gender non-conforming persons. Staff training is essential to provide ethical care for aging trans persons who require residential care. This presentation examines current staff training modules of 100 Long Term Care (LTC) facilities, assessing training needs to provide affirming, culturally competent, and ethical care for sexual and gender minorities.

Keywords: cultural competence; Long Term Care; staff training; transgender

CULTURAL SAFETY WITHIN THE INDIGENOUS HEALTH CONTEXT: FINDINGS FROM A REVIEW OF REVIEWS

Juanita-Dawne Bacsu,¹ Christina Chakanyuka,² Andrea DesRoches,³ Jennifer Walker,⁴ Jessy Dame,⁵ Megan O'Connell,¹ Paisly Symenuk,⁶ and Lisa Bourque Bearskin,⁷ 1. *University of Saskatchewan, Saskatoon, Saskatchewan, Canada*, 2. *University of Victoria, Victoria, British Columbia, Canada*, 3. *University of*

Saskatchewan, University of Saskatchewan, Saskatchewan, Canada, 4. Laurentian University, Sudbury, Ontario, Canada, 5. UBC, Vancouver, British Columbia, Canada, 6. Independent, Edmonton, Alberta, Canada, 7. Thompson Rivers University, Kamloops, British Columbia, Canada

First Nations, Inuit, and Métis older adults often face systemic barriers to accessing culturally safe and equitable healthcare, including racism, structural injustice, and a historical legacy of colonialism. However, there is a paucity of knowledge on cultural safety interventions and implementation strategies in care for older adults. This presentation aims to: 1) explore persistent barriers to achieving health equity and advancing cultural safety in healthcare; and 2) identify cultural safety interventions to improve healthcare for Indigenous older adults. Guided by Arksey and O'Malley's scoping review framework, we conducted a review of reviews published between January 2010 to December 2020 on Indigenous cultural safety in healthcare. We searched five databases (CINAHL, PubMed, Scopus, Web of Science, and Google Scholar) and hand-searched reference lists of relevant articles. We conducted a thematic analysis to identify patterns and themes in the literature. Key barriers to achieving health equity and advancing cultural safety in healthcare included care providers lacking knowledge of Indigenous culture, power imbalances, racism, and discrimination. A range of cultural safety interventions were identified, from education and training initiatives for healthcare providers (emergency physicians and occupational therapists) to collaborative partnerships with First Nations, Inuit, and Métis communities. As First Nations, Inuit, and Métis populations age, there is a growing need for safe healthcare services for Indigenous older adults, and these findings suggest focusing on healthcare providers knowledge and attitudes is key. Research is necessary to develop, implement, and evaluate cultural safety interventions aimed at healthcare providers to improve healthcare for Indigenous older adults.

CUMULATIVE COVID-19 DISPARITIES IN NURSING HOME: FOCUSING ON GEOGRAPHICAL FACTORS AND RACIAL COMPONENTS

Sungjae Hong,¹ and Shannon Meija,² 1. *University of Illinois-Urbana-Champaign, Champaign, Illinois, United States*, 2. *University of Illinois, Champaign, Illinois, United States*

The impact of COVID-19 has been greatest in vulnerable US populations. This study examines the cumulative geographical and racial disparities of COVID-19 cases in nursing homes. Analysis of COVID-19 Nursing Home Data from Centers for Medicare & Medicaid Services was limited to weekly reports from the nursing homes that reported the ratio of black residents, from 2020-05-31 to 2021-01-17 (N=268,222 from 8,026 nursing homes). The outcomes were weekly COVID-19 cases and death per 1,000 occupied beds. Nursing homes were categorized by a geographic (rural vs. urban) and racial composition (>50% of residents are black vs. else). Elapsed time and county-level weekly COVID-19 cases and deaths/1,000 people were the key covariates. Multilevel zero-inflated negative binomial regression revealed evidence of cumulative COVID-19 disparity between rural and urban nursing homes. At the earliest time, COVID-19 incidence was lower in rural nursing homes than in urban nursing homes (IRR=0.406 for cases, 0.034 for death). The significant interaction with time implied

that, over and above evolving disease prevalence, rural nursing homes became more likely than urban nursing homes to experience COVID-19 over time (IRR=1.057 for cases, 1.193 for death). Nursing homes, with >50% black residents, were more likely to experience COVID-19 than their counterparts at the earliest time (IRR=1.339 for cases, 5.630 for death), but independent of local disease prevalence, this disparity decreased over time (IRR=0.973 for cases, 0.972 for death). Our findings suggest that racial and geographic factors contribute to the cumulation of disadvantage during the COVID-19 crisis at the second half of 2020.

EXPERIENCES OF BLACK AND WHITE FAMILY HOSPICE CAREGIVERS: ANXIETY, DEPRESSION, QOL, BURDEN, HOSPICE COMMUNICATION

Lauren Starr,¹ Karla Washington,² Subhash Aryal,³ Debra Parker Oliver,² and George Demiris,⁴ 1. *University of Pennsylvania, Philadelphia, Pennsylvania, United States*, 2. *Washington University in St. Louis, St. Louis, Missouri, United States*, 3. *University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania, United States*, 4. *School of Nursing, University of Pennsylvania, University of Pennsylvania, Pennsylvania, United States*

Although hospice care benefits seriously ill patients and their families, growing evidence suggests anxiety, depression, and altered quality of life are prevalent among family hospice caregivers. It is unknown if Black and white family hospice caregivers experience differences in mental health, quality of life, caregiver burden, or quality of hospice communication. In this secondary analysis of baseline data collected from 717 family hospice caregivers in two randomized clinical trials, we compared anxiety (GAD-7), depression (PHQ-9), quality of life (CQLI-R), caregiver burden (Zarit), and caregiver-reported quality of hospice team communication (CCCQ) between Black and white caregivers. Black and white caregivers differed demographically across multiple variables. In bivariate analysis, we found no differences in depression (P=0.3536), anxiety (P=0.0733), caregiver burden (P=0.6680), and perceptions of caregiver-centered hospice communication (P=0.4549). White caregivers reported lower quality of life than Blacks (P=0.0386), specifically in emotional (P=0.0321) and social (P=0.0002) domains. Financial and physical quality of life did not differ. In multivariate regression analyses controlling for caregiver and patient factors, we found no racial differences in depression (P=0.5071), anxiety (P=0.7288), quality of life (P=0.0584), caregiver burden (P=0.9465), or hospice communication (P=0.8779). Variables explained 7.7% to 20% of variability in outcomes, suggesting research is needed to understand which other factors contribute to hospice caregiver coping and communication experiences. Results suggest Black and white informal hospice caregivers experience similar levels of anxiety, depression, burden, and perceptions of hospice team communication quality. Interventions to support hospice caregivers across racial groups are needed.

EXPLORE THE IMPACT OF ALCOHOL AND OTHER DRUG USE ON HIV CARE AMONG AFRICAN AMERICAN OLDER ADULTS LIVING WITH HIV/AIDS
Lesley Harris,¹ Sydney Silverstein,² Timothy Crawford,² Jelani Kerr,¹ and Diana Ball,¹ 1. *University of Louisville*,

Louisville, Kentucky, United States, 2. Wright State University, Dayton, Ohio, United States

For people living with HIV, there are multiple barriers to engagement with care. This study qualitatively examines the role of use of alcohol and other drugs (AOD) on the health and management of Human Immunodeficiency Virus (HIV) disease among older African Americans (≥ 50 years). It draws on interviews conducted with twenty-seven older African Americans living with HIV in the Louisville, Kentucky area. Interviews were transcribed verbatim and then analyzed using constructivist grounded theory analytic techniques. Participants' understandings of their AOD use fell on a continuum of problematic use to use for self-care. Regardless of where participants fell on this continuum, they faced a) environmental impacts of AOD use and b) current or historic discrimination from the health care system. The analysis focused on gaining a deeper understanding of the intersection of AOD use and engagement in the HIV care continuum. This revealed six major phases, which occurred at various stages of the continuum: (1) Linking AOD use as the cause of HIV diagnosis (2) Having AOD use facilitate denial of HIV, (3) Experiencing problematic use, (4) "Testing the Waters," (5) Relying on AIDS Service Organizations (ASO) and medical providers and (6) Maintaining health and/or using AOD for self-care. We discuss the ways that stigma along the lines of race, gender, and age intersect with co-occurring conditions such as substance use disorders in complex and multifaceted ways. Recommendations include assessing a patients' AOD use in relationship to the HIV care continuum to assess patients' experiences and barriers within systems of care.

GEOGRAPHIC VARIATION IN GENDER GAP AMONG OLDER ADULTS IN INDIA AND CHINA: APPLICATION OF A NEW AGEING MEASURE

Arun Balachandran,¹ and Feinian Chen,² 1. *University of Maryland College Park, Hyattsville, Maryland, United States, 2. University of Maryland College Park, University of Maryland, Maryland, United States*

A continuous rise in the life expectancy of females above that of the males among older adults in India and China may give an impression that the gender gap in health is decreasing. However, given the systemic bias against females in these countries across multiple facets, and the diversity across provinces, a fuller understanding of gender gap calls for (a) understanding the gender gap in multiple dimensions of health, and (b) understanding the variations across provinces. We estimate a multi-dimensional old-age threshold (MOAT) across provinces in India and China, that specifies different old-age thresholds for female and male populations after simultaneously accommodating for multiple dimensions related to their health. These aspects of health include remaining life expectancy, intellectual and functional health. We estimate the gender gap across provinces in these countries by differencing the MOAT of males against that of females. In addition, we also illustrate the gender gap across individual dimensions of health. Our results show that females in almost all the provinces of India and China have a lower MOAT than their male counterparts, showing an earlier advent of 'old-age' among females compared to males. The estimates based on remaining life expectancy shows gender gap in favor of females, but the estimates of

multi-dimensional gender gap are higher and biased against females. A huge variation is seen across provinces, with Karnataka and Hubei showing lower levels of gender gap and Rajasthan and Yunnan showing higher gender gaps in India in China respectively.

HEALTH LITERACY AND HEALTH CONDITIONS AT THE INTERSECTIONS OF GENDER AND RACE IN LATER LIFE

Takashi Yamashita,¹ Darren Liu,² Betty Burston,³ and Jennifer Keene,³ 1. *University of Maryland, Baltimore County, Baltimore, Maryland, United States, 2. Des Moines University, Des Moines, Iowa, United States, 3. University of Nevada, Las Vegas, Las Vegas, Nevada, United States*

The benefits of health literacy are well-documented. Health literacy is a set of skills to locate, understand, and use health-related information to make optimal health decisions. However, relatively less is known about the long-term relationship between health literacy and overall health conditions among older adults. Additionally, health literacy and health at the intersection of gender and race/ethnicity, rather than gender and race separately, are yet to be investigated. This study analyzed sub-samples ($n = 1,260$ adults age 50+) of the 2010 Health and Retirement Study (HRS) health literacy module data, and the 2012, 2014, and 2016 HRS data to examine the trajectories of health based on eight physical and mental conditions (0-8 points: better-worse) among older adults. Latent growth curve mixture models were used to investigate the changes in health and six groups defined by gender (women and men) and race/ethnicity (White, Black, and Hispanic). Results showed that overall health deteriorated over time (latent-slope = 0.19, $p < 0.001$) but the trajectories were diverse (latent-slope variance = 0.06, $p < 0.001$). Greater health literacy (0-5 points: worse-best scaling), which was measured with a validated scale, was associated with better overall health only among White women and men. Notably, White women received the baseline health benefits ($b = -0.20$, $p < 0.05$) from health literacy whereas Black women ($b = 0.09$, $p > 0.05$) did not [$\Delta b = 0.09 - (-0.20) = 0.29$, $p < 0.05$]. Other detailed comparisons, theoretical explanations, and public health policy implications for diverse older populations were evaluated.

I KNOW I'M HEALTHY BECAUSE: QUALITATIVE DEFINITIONS OF HEALTH IN OLDER RURAL AFRICAN-AMERICANS

Carolyn Adams-Price,¹ and Muhammed Riaz,² 1. *Mississippi State University, Mississippi State, Mississippi, United States, 2. Mississippi State University, Mississippi State University, Mississippi, United States*

In recent years, there has been attention to health disparities between racial groups in the US, and between urban and residents. Older rural African Americans are at high risk, but have historical reasons for distrust the health care system. This study examined qualitative definitions of health in older rural African Americans. Our sample included 47 African Americans aged 52-79 (20 male, 27 female, median age = 66) from non metropolitan counties in northeast Mississippi, at least 10 miles from the nearest town of more than 1000. Participants rated their health on a 5-point scale; only 1 person rated their health as a 5 for excellent. On

average, they rated their health as fair. Most reported significant health problems, (mean=2) including 17 (36%) who reported having been diagnosed with diabetes. Participants were asked by interviewers “how they knew they were healthy.” Their responses were transcribed. Using phenomenological methods, participants’ responses were sorted into naturally-occurring categories, which were retested against the data. The categories that emerged were Performing Basic Tasks is Enough/I’m OK (12), Good Health Due to Healthy Behaviors (8), Healthy Due to Social Support or God (11), Healthy Despite One Problem (6), and I’m Not OK (7). Given that our sample is somewhat younger than most gerontological samples, participants seemed to have relatively low expectations about their health, which might not be surprising considering the health problems in the sample. Interventions to improve the health of this group should concentrate on increasing health self-efficacy and expectations.

INTERSECTIONS OF GENDER AND RACE AMONG OLDER WORKERS DURING THE COVID-19 PANDEMIC

Takashi Yamashita,¹ Wonmai Punksungka,¹ Samuel Van Vleet,² Abigail Helsing,³ and Phyllis Cummins,² 1. *University of Maryland, Baltimore County, Baltimore, Maryland, United States*, 2. *Miami University, Oxford, Ohio, United States*, 3. *Scripps Gerontology Center, Miami University, Oxford, Ohio, United States*

The novel coronavirus/COVID-19 pandemic in 2020 has impacted the aging workforce. In addition to local data and case studies that are rapidly increasing, baseline national-level inquiries are needed for investigating relevant social inequalities. Also, the intersections of gender and race/ethnicity among older adults are critical yet understudied areas. For example, older minority women’s experience in the pandemic, compared to older men, are yet to be investigated. We analyzed the nationally representative 2020 Health and Retirement Study (HRS) COVID-19 module data. Based on the sample of 2,086 adults aged 50 years and older, employment during the pandemic as well as psychosocial measures, including social support and attitudes toward work, are examined. We used survey-weighted binary logistic regression models. Results showed that older Black women (Odds-ratio = 0.52, $p = 0.02 < 0.05$) were less likely to work for pay compared to White women during the pandemic. Also, older Hispanic men (Odds-ratio = 2.82, $p = 0.03 < 0.05$) were more likely to work for pay than older White men. Older Hispanic women (Odds-ratio = 2.41, $p = 0.03 < 0.05$) were more likely to worry about getting social support during the pandemic than White women. However, there was no significant differences in the changes in attitudes toward work across gender and racial/ethnic groups during the pandemic. Based on the baseline national data analysis, we discussed possible policy changes and interventions that consider the intersections of gender and race/ethnicity to help older adults re-adjust to post-pandemic work environments and labor markets.

KEEP ON KEEPIN’ ON: INVESTIGATING ACES AND POSITIVITY AMONG BEREAVED BLACK MIDDLE AGED AND OLDER ADULTS

Danielle McDuffie, *The University of Alabama, Tuscaloosa, Alabama, United States*

Many of the most damaging life events are more prevalent among Black older adults. Black people have been found to have higher amounts of adverse childhood experiences (ACEs), which are linked to detrimental life impacts. Additionally, bereavement occurs at a higher rate among Black people and older adults. Despite these challenges, Black older adults have been repeatedly cited overcoming these challenges. Accordingly, the present study sought to investigate whether Black middle to older aged adults who encountered two of life’s most difficult challenges (i.e. bereavement and ACEs) would still maintain positivity. 103 middle to older Black adults ($M=44.72$, $SD=5.48$, 67% male) from a larger online grief study were probed about factors including time since loss, positive outlook, and ACEs. A linear regression and mediation analysis were used to analyze the data. ACEs were found to significantly predict positive outlook among bereaved middle to older Black adults ($F=11.46$, $p=.001$), such that as the number of ACEs increased, so did positivity in spite of bereavement. Notably, this association was not mediated by time since loss. Results from this study provide evidence that even when faced with some of life’s most difficult events, Black middle to older adults were still able to reframe their situation with a positive focus. The ability for Black middle to older aged adults to reframe their tragedies into positivity could provide a basis for the use of Positive Psychological techniques specifically within this population. Additionally, this study provides further evidence that Black people exhibit exceeding resilience.

MANIFESTATIONS OF RACIAL TRAUMA IN BEREAVED MIDDLE TO OLDER AGED BLACK ADULTS

Danielle McDuffie, *The University of Alabama, Tuscaloosa, Alabama, United States*

Black adults have a higher likelihood of experiencing bereavement and increased negative implications of systemic racism compared to other groups. The effects of racism have also been suggested to have an impact on how bereaved Black individuals conceptualize their loss and the deceased. However, there is limited literature on how direct and indirect childhood experiences with racial violence and viewing racially violent deaths impact bereaved Black adults later in the lifespan. The current study seeks to explore the impacts childhood engagement with racial violence might have on bereaved middle to older Black adults. 103 middle to older aged Black adults ($M=44.72$, $SD=5.48$, 67% male) from a larger online grief study were probed about factors including somatization, depression, affect, grief, and the prevalence and intensity of exposure to race-based violence during their childhoods. Linear regressions and bivariate correlations were used for data analysis. Childhood racial violence significantly predicted grief ($F=6.348$, $p=.013$). Additionally, experiencing childhood racial violence was significantly associated with somatization ($r=.197$, $p=.047$), depression ($r=.198$, $p=.045$), and negative affect ($r=.256$, $p=.010$). Endorsed intensity of racial violence was significantly associated with depression and negative affect ($r=.464$, $p=.000$; $r=.440$, $p=.000$, respectively). Bereaved Black middle to older adults seem greatly impacted by childhood experiences of racial violence. It is important to consider the role outside cultural influences such as racial trauma might have on other deleterious mental

health experiences such as bereavement. Furthermore, in the assessment of ACEs among Black and other people of color, it could be important to include childhood racial violence.

MINORITY STRESS IN THE CONTEXT OF THE DISABLEMENT PROCESS MODEL

Jeffrey Lentz, *University of North Georgia, Oakwood, Georgia, United States*

The changing demographics and growing diversity in the United States pose significant challenges for researchers, particularly scholarship involving sexual minority adults' health and aging processes. Not much is known about how all minority stressors could lead to a disability. Sexual minority adults are at a greater risk of developing a disability later in life than their heterosexual counterparts (Fredriksen-Goldsen, Kim, & Barkan, 2012). Drawing from critical components of the disablement process model (Verbrugge & Jette, 1994), this dissertation sought to understand the relationship between minority stress and disability status among sexual minority adults 50 years and older. Minority stress in the context of the disablement process model is a social condition. While exploring the relationship between minority stress and disability status, intra-individual factors and extra-individual factors were assessed to see if they mediated the relationship between minority stress and disability status among sexual minorities 50 years and older. Discrimination is significantly associated with having a disability. None of the intra-individual factors and extra-individual factors mediated the relationship between minority stress and disability; however, several intra- and extra-individual were associated with greater or lesser odds of experiencing a disability. This dissertation concluded that discrimination is associated with disability status among sexual minority adults 50 years and older. On the other hand, the disablement process model does not support minority stress as a social condition leading to a disability. On the other hand, this dissertation's results support the ideology that experiencing discrimination is associated with a disability.

MOTIVATION TO LEARN AT THE INTERSECTIONS OF AGE, GENDER, AND RACE

Takashi Yamashita,¹ Thomas Smith,² Shalini Sahoo,¹ and Phyllis Cummins,³ 1. *University of Maryland, Baltimore County, Baltimore, Maryland, United States*, 2. *Northern Illinois University, DeKalb, Illinois, United States*, 3. *Miami University, Oxford, Ohio, United States*

Continuing adult education and training, or lifelong learning, has become increasingly important to fully engage in rapidly changing technology and information-rich societies. However, without motivation to learn (MtL), lifelong learning participation is unlikely to occur. Although previous research has identified lifelong learning gaps by various demographic characteristics, including age, gender, and race/ethnicity, little is known about the intersectionality or differences in MtL across specific sub-groups (e.g., older Black women vs. older Black men) at the national level. The current study analyzed U.S. data from the 2012/2014/2017 Program for International Assessment of Adult Competencies (PIAAC) to examine MtL at the intersections of age (five 10-year age groups), gender (women vs. men), and race (White vs. Black). The previously established 4-item latent MtL construct was

evaluated for twenty sub-groups using the alignment optimization method, which is a machine learning algorithm for latent mean estimation and simultaneous multiple group comparisons. Results showed that the latent MtL construct was validly measured across the sub-groups, and the estimated sub-group means were then used to develop a national MtL profile. Overall, older adults tended to have lower MtL than younger age groups. Notably, compared to than older Black men age 66+ years, older White men aged 55-65 and 66+ years old had lower MtL (latent mean differences of -0.29 and -0.41, respectively, $p < .05$). Additionally, older Black women had significantly lower MtL than older Black men (latent mean difference = -0.50, $p < .05$). The national MtL profiles, the intersectionality and policy implications were discussed.

MULTIMORBIDITY TRAJECTORY CLASSES AS PREDICTED BY RACE, ETHNICITY, AND SOCIAL RELATIONSHIP QUALITY

Jason Newsom,¹ AnneMarie O'Neill,¹ Emily Denning,¹ Ana Quiñones,² Anda Botoseneanu,³ Heather Allore,⁴ Corey Nagel,⁵ and David Dorr,² 1. *Portland State University, Portland, Oregon, United States*, 2. *Oregon Health & Science University, Portland, Oregon, United States*, 3. *University of Michigan - Dearborn, Dearborn, Michigan, United States*, 4. *Yale School of Medicine, New Haven, Connecticut, United States*, 5. *University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*

Growth mixture modeling was used to classify multimorbidity (≥ 2 chronic conditions) trajectories over a 10-year period (2006-2016) in the Health and Retirement Study (N = 7,151, mean age = 68.6 years). Race/ethnicity (non-Hispanic Black, Hispanic, non-Hispanic White) and social relationship quality (positive social support and negative social exchanges, such as criticisms) were then used to predict trajectory class membership, controlling for age, sex, education, and wealth. We identified three trajectory classes: initial low levels and rapid accumulation of multimorbidity (increasing: 12.6%), initial high levels and gradual accumulation of multimorbidity (high: 19.5%), and initial low levels and gradual accumulation of multimorbidity (low: 67.9%). Blacks were more than twice as likely to be in the increasing (OR = 2.04, CI[1.29,3.21]) and high (OR = 2.28 CI[1.58,3.206]) multimorbidity groups compared with Whites, but there were no significant differences between Hispanics and Whites for either trajectory class (OR = .84 CI[.47,1.51] and OR = .74 CI[.41,1.34], respectively). Increments in perceived support were associated with significantly lower risk of membership in the increasing (OR = .59, CI[.46,.78]) and high classes (OR = .54 CI[.42,.69]), and increments in negative exchanges were associated with significantly higher risk of membership in the increasing (OR = 1.64 CI[1.19,2.25]) and high classes (OR = 2.22 CI[1.64,3.00]). These results provide important new information for understanding health disparities and the role of social relationships associated with multimorbidity in middle and later life that may aid in identifying those most at risk and suggesting possible interventions for mitigating that risk.

PERSPECTIVES ON AGING WELL AMONG OLDER BLACK WOMEN IN THE US

Jacquelyn Coats, *Brown School, Washington University in St. Louis, Saint Louis, Missouri, United States*

Despite changes in the demography of older Black women who are living longer, there is limited research on how older Black women conceptualize and understand successful and healthy aging. The objective of this presentation is to interrogate the meaning and cultural aspects of aging among older Black women, gaining insight into how gender and race operate and intersect to shape experiences and perceptions of aging. Using an intersectionality framework, this qualitative study was conducted with three older Black women. The women ranged in age from 58-65 years old, each residing in an US urban city (Detroit, St. Louis, Atlanta). Data were collected between October and November 2020, using a semi-structured, open-ended interview protocol to encourage participants to provide in-depth descriptions of how they conceptualized aging. Interviews were between 2 – 2.5 hours, conducted via videoconferencing, and audio-recorded for transcription. Participants discussed: the life experiences that have shaped their ability to age well; what it means to age well, and factors that might hinder someone from aging well. Transcripts were coded using a constructivist grounded theory approach. Results revealed six themes Black women in later life identify: aging well, aging as a mindset, independence and freedom, authenticity, personal control and preparation, and aging role models. This extends the knowledge base on how older Black women view aging and factors that enhance or diminish their ability to age well. Results from this study can be used to enhance the development of public health and social work interventions with older Black women.

RACE/ETHNICITY, VASCULAR AGING, AND MORTALITY RISK: EVIDENCE FROM THE HEALTH AND RETIREMENT STUDY

Kevin Heffernan, Janet Wilmoth, and Andrew London, *Syracuse University, Syracuse, New York, United States*

Vascular aging, which is associated with cardiovascular disease risk and mortality, is characterized by increasing arterial stiffness. The gold standard method for the assessment of arterial stiffness is carotid-femoral Pulse Wave Velocity (cfPWV). An emerging body of research suggests that cfPWV can be reasonably estimated from two commonly measured clinical variables—age and blood pressure. Thus, estimated Pulse Wave Velocity (ePWV) holds promise as a novel and easily obtained measure of arterial stiffness that can be used to study vascular aging, particularly with nationally representative datasets that collect biomarker data on sufficiently large sample sizes to examine race/ethnic differences. This analysis uses data from the 2006-2016 Health and Retirement Study to examine race/ethnic variation in the relationship between ePWV and mortality risk. We estimate logistic regression models predicting mortality over an eight-year period for four racial/ethnic groups: White, Black, Other, and Hispanic. Controls are included for sociodemographic characteristics, health status and behaviors, and blood biomarkers such as C-reactive protein, cystatin-C, hemoglobin A1c, total cholesterol and high-density lipoprotein (HDL) cholesterol. The results indicate ePWV increases the risk of mortality in the total sample and among each race/ethnic group, net the effect of age, systolic blood pressure, and diastolic blood pressure. Mechanisms that mediate this relationship are explored. The findings provide insight into vascular aging processes that influence mortality risk among race/ethnic groups.

RACIAL/ETHNIC DIFFERENCES IN THE LONGITUDINAL EFFECTS OF FEAR OF FALLING ON FALLS

Tuo Yu Chen,¹ and Giyeon Kim,² *1. Taipei Medical University, Taipei, Taipei, Taiwan (Republic of China), 2. Chung-Ang University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Research suggests that the effects of fear of falling on falls may differ by race/ethnicity. We investigated whether race/ethnicity (White, Black, and Hispanic) moderated the longitudinal effects of fear of falling on the incidence of falling and having a repeated fall among community-dwelling older adults. We used data from 2011-2018 of the National Health and Aging Trends Study (NHATS). These included a total of 19,516 person-intervals from 5,113 respondents. Self-reported any fall in the past year was the outcome variable with baseline fear of falling as the predictor and race/ethnicity as the moderator. Known risk factors for falls were included as covariates. Results showed that among respondents without the experience of falling at baseline, baseline fear of falling significantly increased the odds of a new-onset of fall at 1-year follow-up among Blacks, compared to Whites. Among respondents who already fell at baseline, baseline fear of falling significantly increased the odds of having a repeated fall later on among Hispanics, compared to Whites. Clear evidence of racial/ethnic differences was found in the relationship between fear of falling and falls among community-dwelling older adults in the U.S. Special attention should be paid to Black older adults with a fear of falling but have not fallen down recently and Hispanics with fear of falling and have fallen in the past year. Readily available educational programs should be actively advertised to older adults to reduce the fear of falling and culturally tailored educational programs should be developed for older adults from racial/ethnic minority backgrounds.

RELATIONSHIP BETWEEN MEANINGFUL ACTIVITY ENGAGEMENT AND WELL-BEING MODERATED BY RACE

Dugan O'Connor, and Jennifer Smith, *Mather, Evanston, Illinois, United States*

Engaging in meaningful activities has benefits for health and well-being in older adults; however, racial differences in meaning from activities have been observed. The current study examined how the relationship between engagement in a variety of meaningful activities and well-being differs for Black and White older adults. Participants (130 White and 101 Black older adults), ages 53 to 90 (M=69), completed an online survey that measured the extent to which engaging in various activities provided meaning or fulfillment as well as measures of purpose in life, positive affect, negative affect, and loneliness. Overall, the most meaningful activities included “spending time with family,” “reading,” and “being outdoors/experiencing nature.” The least meaningful activities included “job/career,” “caring for pets/animals,” and “supporting a social or political cause.” Black older adults reported greater meaning from “religious faith,” “spiritual practices/meditation,” “spending time with family,” and “listening to music,” and less meaning from “caring for pets/animals,” compared to White older adults. A series of multiple regression analyses (with age, gender, education, and income

as covariates) revealed that greater meaning across activities was associated with lower loneliness, regardless of race. Significant Meaning x Race interactions revealed meaning was positively associated with sense of purpose and positive affect for Black but not White older adults. These findings suggest that finding meaning in leisure activities is a psychological resource that may contribute to Black older adults' well-being. The racial differences in sources of meaning further support the importance of considering the target population when designing activity programs for older adults.

THE EFFECTS OF LATENT CLASSES OF STRESS ON HEALTH OUTCOMES IN KOREAN MIDDLE-AGED ADULTS: A FOCUS ON GENDER DIFFERENCES

Kyuyoung Cho, *Dong-A University, Busan, Pusan-jikhalsi, Republic of Korea*

This study indicated the effect of the latent classes of stress on the physical and psychological health outcomes in Korea. Using the 2010 Korea Health Panel Study, 1,689 middle-aged adults (women: $n=793$, men: $n=896$) were analyzed to identify the latent classes of stress by gender using Latent Profile Analysis (LPA). After the determination of the number of latent classes, health outcomes (anxiety/depression and health status) were also regressed on the latent classes including covariates (age, marital status, and education level). The perceived stresses (financial diversity, disease of self or family, children's education, and family conflicts) are classified as the 2-class model for women and the 3-class model for men. The classes of women are named 'high stress and 'low stress; however, the classes of men are named 'family-related stress', 'disease stress', and 'low stress.' The different combinations of stress are associated with anxiety/depression and health status respectively. This study will discuss the difference of latent stress classes by gender and extend the understanding of stress groups and health outcomes.

THE INTERACTIVE EFFECTS OF EDUCATION AND SOCIAL SUPPORT ON BLOOD PRESSURE IN AFRICAN AMERICANS

DeAnnah Byrd,¹ Yanping Jiang,² Samuele Zilioli,³ Roland Thorpe,⁴ Peter Lichtenberg,² and Keith Whitfield,⁵
1. *Arizona State University, Phoenix, Arizona, United States*, 2. *Wayne State University, Detroit, Michigan, United States*, 3. *Wayne state university, Detroit, Michigan, United States*, 4. *Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*, 5. *University of Nevada Las Vegas, Las Vegas, Nevada, United States*

This study examined whether the effects of received and provided social support on blood pressure (BP) would differ by education. Data from 602 African American adults (48-95 years) enrolled in the Baltimore Study of Black Aging—Patterns of Cognitive Aging were analyzed using multiple linear regression. We found no main effects of received and provided social support on BP. However, a significant moderation effect was observed for systolic BP, such that greater received social support was positively associated with higher systolic BP among individuals with low levels of education, adjusting for age, sex, chronic health conditions, and depressive symptoms. The findings demonstrate that social support and education have joint effects on blood pressure, which highlights the importance of considering psychosocial

determinants of adverse cardiovascular health outcomes that disproportionately affect African Americans.

THE RELATIONSHIP BETWEEN METABOLIC HEALTH AND MORTALITY AMONG OLDER HISPANICS IN THE US AND MEXICO

Maria Carabello, *University of Michigan, Ann Arbor, Michigan, United States*

Studies consistently show that Hispanics, especially first-generation Mexican immigrants, face lower mortality risks in mid-to-late life than US-born non-Hispanic whites. This extended lifespan defies expectations given Hispanics' disadvantaged socioeconomic status relative to whites and thus is referred to as the Hispanic paradox. However, it remains an open question as to whether the Hispanic paradox in mortality mirrors a lower chronic disease burden. To address this gap, this study will combine and leverage two harmonized longitudinal population-based data sources of late-middle-aged and older adults in the United States and Mexico; the Health and Retirement Study and the Mexican Health and Aging Study. First, I evaluate differences in the association between metabolic syndrome (MetS) and mortality risk for older adults living in Mexico, first-generation Mexican immigrants to the US, US-born Mexican Americans, and US-born whites. Second, I explore the extent to which the proportion of deaths attributable to MetS in each of these groups can be explained by differences in socioeconomic and health/behavioral characteristics. This study uses Cox proportional hazards models to estimate the mortality risks of MetS across groups, as well as the associated population attributable fractions (PAFs) to investigate potential differences within a decomposition framework. Developing this detailed understanding of metabolic health and the associated mortality risks across multiple generations of older Mexican immigrants may help us identify modifiable lifestyle and behavioral factors to better manage these conditions and alleviate possible complications as current and future generations of Mexican immigrants age in the US.

THE UTILITY OF SOCIAL MEDIA RECRUITMENT TO ACHIEVE A MORE DIVERSE PARTICIPANT SAMPLE

Faith-Christina Washington,¹ Tai-Te Su,² Aileen Griffin,³ Jacob Sosnoff,⁴ and Shannon Meija,⁵ 1. *University of Illinois at Urbana-Champaign, Champaign, Illinois, United States*, 2. *University of Illinois at Urbana-Champaign, United States*, 3. *University of Illinois at Urbana-Champaign, Aurora, Illinois, United States*, 4. *School of Health Professions, University of Kansas Medical Center, Kansas City, Kansas, United States*, 5. *University of Illinois, Champaign, Illinois, United States*

The COVID-19 pandemic created an immediate, lasting impact on recruitment methods in academic research, most notably in the field of gerontology. To protect older adult participants' health during the COVID-19 crisis, the Daily Balance Project, a 30-day micro-longitudinal study of older adults' awareness of balance in daily life, shifted to complete remote administration. Our new remote protocol included developing new methodologies to recruit participants with varying degrees of fall risk and educational attainment. In

this study, we present our approach to remote online recruitment and compare educational attainment, objective and subjective fall risk, and alignment of objective/subjective fall risk across three samples recruited via a) Fall Clinic registry (16 participants); b) University e-newsletter to faculty and staff (5 participants); c) social media recruitment (7 participants). Eligibility included being 65+ and wireless internet at home. For samples a and b, screening assessments were conducted via phone while baseline assessments were conducted in-person. For sample c, screener and baseline assessment were virtual. Analysis of recruitment methods aims to determine whether recruitment via social media platforms may provide a sample of participants with more variation in fall risk or alignment of subjective versus objective balance. Results demonstrate no significant differences in educational attainment ($p=0.7949$) or balance confidence ($p=0.213$), despite significant differences in the alignment of objective and subjective fall risk ($p=0.031$). Participants from samples a and b proved more able to accurately assess fall risk, while sample c had the most misalignment between subjective and objective fall risk assessments.

Session 9385 (Poster)

Minority and Diverse Populations

ARE AGE DIFFERENCES BETWEEN PARTNERS RELATED TO GENDER AND GENERATIONS AMONG MIDDLE-AGED AND OLDER ASIAN AMERICANS?

Minzhi Ye,¹ and Di Mei,² 1. *Benjamin Rose Institute on Aging/Case Western Reserve University, Benjamin Rose Institute on Aging, Ohio, United States*, 2. *The University of Hong Kong, The University of Hong Kong, Hong Kong*

Previous research has shown that women who immigrate to the United States tend to partner with much older spouses. However, most studies have focused on young people and first-generations. Spousal age differences among older Asian Americans with different generations have not been well studied. Using data from the Annual Social and Economic Supplement survey (2013-2019), we employed the segmented assimilation theory to test 7,064 married middle-aged and older (50+) Asian Americans. Logistic regression analyses were conducted to understand the association between spousal age differences and individual background, including gender, ethnicity, socioeconomic status, generation, and marriage types. Of the 3,342 men, 20% were married to wives at least 6 years younger and 2% were married to wives at least 6 years older. Men who were Japanese or had inter-ethnic marriages were more likely to marry women at least 6 years older. Men who were Indian, Vietnamese, or having an interracial marriage were more likely to marry women at least 6 years younger. Of the 3,722 women, 3% were married to husbands at least six years younger and 19% were married to husbands at least six years older. Women who were Indian or Vietnamese were more likely to marry men at least six years older. Women who had a high school diploma or were third-plus generation were more likely to marry men at least 6 years younger. The findings reflect the complexity of Asian senior marriage and provide insight for policymakers to design new or improved social integration programs for senior immigrants.

BARRIERS THAT CONTRIBUTE TO THE DIGITAL DIVIDE AMONG OLDER COMMUNITY DWELLING ADULTS IN LATER LIFE

Haowei Wang,¹ Mai See Yang,² and Yong Kyung Choi,³

1. *The Pennsylvania State University, University Park, Pennsylvania, United States*, 2. *UC Davis, UC Davis, California, United States*, 3. *University of California Davis School of Medicine, Sacramento, California, United States*

Research demonstrates that race and health literacy contribute to the digital divide, which is a major public health concern for older adults in the U.S. However, we still lack information about what types of barriers older adults have through a comprehensive examination using population-based data. This study focuses specifically on barriers to technology use among older adults. We use data from the Health and Retirement study 2012 Module "Technology Use: Barriers and Benefits" ($N = 1,416$). About 42% of participants did not use any technology (e.g., emails, social media, smart phone) ($n = 501$). The mean age for this non-user group was 72 years old (SD 10.3). 13% were foreign born, over half were female (56%), and the majority were somewhat educated (72% with a high school education or lower). About 23% of non-users were self-reported black, 16% Hispanic, 3% other race, and 58% non-Hispanic white. Barriers for adopting the use of technology included too difficult to keep up with the changes in technology (78%), too complicated (69%), not interested (65%), too much time required to learn (53%), too hard to learn (52%), expensive (43%), not easily available (24%), and opposed to using new technologies (27%). Results suggest that barriers were significantly correlated with more depressive symptoms among older adults who did not use technology. Compared to users, non-users were also more likely to have health conditions (e.g., hypertension, diabetes, lung disease, stroke, and arthritis). Findings of this study provide directions to address digital divide among older adults.

DOES LEVEL OF EQUALITY IN STATE OF RESIDENCE RELATE TO LGBT HEALTH? AN ANALYSIS OF ADULTS AGED 50+ YEARS FROM 34 US STATES

Christi Nelson, and Ross Anel, *University of South Florida, Tampa, Florida, United States*

Lesbian, gay, bisexual, and transgender (LGBT) health disparities have been well documented in previous research. This study examined whether the level of equality in state of residence (high, medium, fair, poor, or negative), determined by tallied LGBT-related laws and policies, was associated with health outcomes for LGBT adults. This study consisted of 3486 LGB and 959 transgender adults ages 50+ as well as 1:1 propensity matched heterosexual and cisgender participants from the 2018 and 2019 Behavioral Risk Factor Surveillance System (BRFSS) surveys. Separate logistic regression analyses for the LGB, transgender, heterosexual, and cisgender groups were conducted to assess health differences by state equality ranking. Results indicated that LGB participants in fair ranked states were more likely to report fair/poor general health ($aOR=1.4$, 95% $CI=1.1-1.8$) and 14 or more days of poor mental health in the past 30 days ($aOR=1.4$, 95% $CI=1.1-1.9$) compared to LGB in high ranked states. LGB participants in a low or negative ranked state were more likely to report fair/poor health ($aOR=1.6$, 95% $CI=1.3-2.0$), 14 days or more of poor physical health ($aOR=1.5$, 95% $CI=1.1-1.8$), and 14

or more days of poor mental health (aOR=1.3, 95% CI=1.0-1.7) in the past 30 days. Transgender participants in medium and low/negative ranked states were more likely to report fair/poor health (lowest aOR=1.75, 95% CI=1.3-2.5) compared to transgender individuals in high equality states. Similar results were not found for the matched heterosexual and cisgender groups. These results suggest that LGBT-related laws and policies may play a role in LGBT health.

EVALUATING THE ECONOMIC IMPACT OF MARRIAGE VERSUS COHABITATION IN SAME-SEX COUPLES AGE 50+

Setarreh Massihzadegan, and Jan Mutchler, *University of Massachusetts Boston, Boston, Massachusetts, United States*

Utilizing the first set of 5-year American Community Survey data available since the United States' legalization of same-sex marriage in mid-2015, this poster investigates the economic security of older adults (age 50+) in same-sex marriages compared to those in same-sex partnerships who are cohabiting but not married. Viewed through the lens of cumulative disadvantage theory, we consider differences in the economic circumstances of same-sex couples by gender and by geographic location. Findings point to gender differences in economic well-being, but relatively few differences based on marital status. For example, rates of low income are somewhat higher among female couples than among their male counterparts, but marital status differences are not substantial. These findings suggest that the benefits of being married that have long been recognized among older adults may not extend equally to same-sex couples. Findings are discussed with respect to the emerging salience of marriage within the LGBTQ older community, future research opportunities, and important policy implications.

THE RELATIONSHIP BETWEEN SOCIAL ISOLATION AND SENSE OF COMMUNITY AMONG OLDER ADULTS IN PUERTO RICO

Thomas Buckley,¹ and Denise Burnette,² 1. *Virginia Commonwealth University, NORFOLK, Virginia, United States*, 2. *Virginia Commonwealth University, Virginia Commonwealth University, Virginia, United States*

Psychological sense of community (SOC) is linked to key health and wellbeing outcomes for older adults and among Latin American populations. Prior research shows that social factors may affect SOC, but this has yet to be studied among Puerto Rican older adults. This study draws on Social Resource Theory to test the hypothesis that social isolation is associated with SOC among older adults in Puerto Rico. We collected data through face-to-face interviews in a non-probability sample of community dwelling adults aged 60+ throughout Puerto Rico in 2019-2020 (N = 154). We measured social isolation with the Spanish translation of the LSNS-6 (range 0-30, mean= 14.00, SD= 5.99), where higher scores indicate less isolation, and SOC with the Spanish translation of the Brief Sense of Community Scale (range 0-32, mean= 24.75, SD= 6.04). This cross-sectional study used multiple linear regression to test the association between social isolation and SOC, while controlling for gender, age, income and living arrangement. Higher scores on the LSNS-6 were associated with higher SOC ($\beta=0.31$, $SE=0.08$, $p<0.001$). Among the sociodemographic covariates, increased age was

associated with higher SOC ($\beta=0.12$, $SE=0.05$, $p<0.05$). This study demonstrates that older adults in Puerto Rico who are more socially isolated have lower SOC, and that SOC increases with age. In order to promote SOC in this population, interventions should focus on reducing social isolation and may benefit from targeting young-old older adults. Future research should continue to examine these relationships and extend to other Latin American cultures.

WHAT'S RACE GOT TO DO WITH IT? HOW PALLIATIVE CARE CONSULTATION MAY MITIGATE RACIAL DISPARITIES IN FUTURE CARE

Lauren Starr,¹ Connie Ulrich,² G. Adriana Perez,³ Subhash Aryal,² Paul Junker,⁴ Nina O'Connor,⁵ and Salimah Meghani,² 1. *University of Pennsylvania, Philadelphia, Pennsylvania, United States*, 2. *University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania, United States*, 3. *University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania, United States*, 4. *University of Pennsylvania Health System, Philadelphia, Pennsylvania, United States*, 5. *Penn Medicine, Perelman School of Medicine, Philadelphia, Pennsylvania, United States*

It is unknown if care and cost outcomes differ by race and ethnicity following discharge from a hospitalization involving palliative care consultation to discuss goals-of-care (PCC). In this secondary analysis of 1,390 seriously-ill patients age 18+ alive at discharge who self-identified as Black, Hispanic, Asian, white, or other race and received PCC at an urban, academic medical center, we used binomial logistic regression and multiple linear regression controlling for demographic and clinical variables to identify factors associated with care experiences and costs following discharge from a hospitalization with PCC. In adjusted analyses, discharge to hospice was associated with Medicaid ($p=0.016$). Thirty-day readmission was associated with age 75+ ($P=0.015$), Medicaid ($P=0.004$), admission 30 days prior ($P<0.0001$), and Black race compared to white ($P=0.016$). Number of future days hospitalized was associated with Medicaid ($P=0.001$), admission 30 days prior ($P=0.017$), and Black race compared to white ($P=0.012$). Having any future hospitalization cost was associated with patient ages 65-74 ($P=0.022$) and 75+ ($P=0.023$), Medicaid ($P=0.014$), admission 30-days prior ($P<0.0001$), and Black race compared to white ($P=0.021$). Total future hospitalization costs were associated with female gender ($P=0.025$), Medicaid ($P=0.009$), admission 30 days prior ($P=0.040$), and Black race compared to white ($P=0.037$). Race or ethnicity was not a predictor of hospice enrollment. Randomized controlled trials are needed to understand if PCC is an intervention that reduces racial disparities in end-of-life care. Qualitative insights are needed to explain how PCC and socioeconomic factors such as Medicaid may mitigate future acute care use among racial and ethnic groups.

Session 9390 (Poster)

Mobility and Disability

ADULTS AGING WITH SPINAL CORD INJURY: PREVALENCE AND ASSOCIATED RISK FACTORS FOR DIAGNOSIS OF DIABETES MELLITUS

Junha Park, and Lisa Bratzke, *University of Wisconsin-Madison, Madison, Wisconsin, United States*

With the increased life expectancy, people aging with spinal cord injury (SCI) are more likely to experience chronic conditions, including diabetes mellitus (DM). The results of previous literature related to the prevalence of DM are mixed and risk factors associated with diagnosis of DM after SCI are not well defined. This study aims to investigate the prevalence of DM and explore associated risk factors for diagnosis of DM among adults aging with long-standing spinal cord injury in the United States. This is a secondary data analysis using the National Spinal Cord Injury Model Systems Database. Participants included 516 people age 45 and older who have been living with SCI for more than 10 years. The prevalence of DM in this sample was 13.2%. Multivariate logistic regression, controlling for confounding variables, was conducted to identify risk factors associated with DM diagnosis in this sample. The multivariate logistic regression model found that the participants who responded with less severe SCI measured by the ASIA impairment scale were less likely to be diagnosed with DM (OR=0.332, $p=.017$). Also, DM was found to be significantly associated with BMI (OR=1.043, $p=.010$) and age (OR=1.038, $p=.010$) respectively. Duration of disability was not significantly associated with DM. Future research is needed to validate these findings and identify other common risk factors for DM such as diet/nutrition. Further, exploration of the effect size of risk factors is also warranted. Such findings will inform interventions to aid prevention and early detection of DM.

AN INTERNATIONAL REVIEW OF MOTOR VEHICLE COLLISION RISK WITH MEDICAL CONDITIONS IN OLDER ADULTS

Mark Rapoport,¹ Joanne Wood,² Jamie Dow,³ Desmond O'Neill,⁴ Judith Charlton,⁵ and Sjannie Koppel,⁵
 1. *University of Toronto, Toronto, Ontario, Canada*, 2. *Queensland University of Technology, Brisbane City, Queensland, Australia*, 3. *SAAQ, Quebec City, Quebec, Canada*, 4. *Trinity College Dublin, Dublin, Dublin, Ireland*, 5. *Monash University, Clayton, Victoria, Australia*

The objective was to examine the impact of seven categories of medical illness on risk of Motor Vehicle Collisions (MVC) in older adults. In late 2019, a systematic review of the MVC risk associated with alcohol use disorders, psychiatric disorders, epilepsy, diabetes, hearing loss, vision disorders and sleep disorders was conducted. A total of 64,720 titles were screened, and 138 articles were included. Of these, only thirteen pertained to older adults, only six showed increased MVC risk in at least one condition, and only seven were rated of "Good" quality. Hearing impairment was associated with MVC only if associated with visual acuity or contrast sensitivity impairments (RR 1.52, 95% CI 1.01-2.3 and RR 2.41, 95% CI 1.62-3.57, respectively). A high depression score was associated with increased MVC (RR 1.5, 95% CI 1.1-2.1) in one study, but a similar relationship was not found in two other studies. Glaucoma increased at-fault MVC risk (RR 1.65, 95% CI 1.20-2.28) in one study, but no relationship was found in another. Visual field loss increased MVC risk in three of four studies (RR or HR ranging from 1.31 to 2.32). One negative study each were identified for alcohol use disorders, age-related macular degeneration, any eye disease, or any psychiatric disorder, and four negative studies were identified for reduced visual

acuity. No studies of older adults were found for epilepsy or sleep disorders. Interpretation of MVC risk in older drivers with medical illness is rendered challenging by the paucity and quality of studies.

BRAIN MAGNETIC SUSCEPTIBILITY IS ASSOCIATED WITH SLOWER GAIT IN COMMUNITY-DWELLING OLDER ADULTS

Victoria Poole,¹ Robert Dawe,¹ Sue Luegans,¹ David Bennett,¹ Aron Buchman,¹ and Konstantinos Arfanakis,² 1. *Rush University, Chicago, Illinois, United States*, 2. *Rush University, Rush Alzheimer's Disease Center, Illinois, United States*

Age-related slowing of gait is exceedingly common and a robust predictor of various adverse health outcomes in older age. Prior neuroimaging studies have documented diverse non-specific structural brain abnormalities which are related to slow gait; however, the extent to which quantitative susceptibility mapping (QSM), which measures regional magnetic susceptibility in the brain, associates with gait speed remains unexplored. In the current study, 415 non-demented community-dwelling older adults (91 males; 81+/- 7 years) underwent an MRI (Siemens 3T TIM Trio) and in-home motor assessment. Gait speed was measured and averaged across 2 timed 8-ft walks. MR-acquired QSM data were pre-processed, registered to ICBM template, and spatially smoothed with a 5mm FWHM Gaussian kernel. When these maps entered group-level GLMs, voxel-wise associations with gait speed were of interest, after adjusting for demographics. We observed very strong negative associations between gait speed and magnetic susceptibility, such that those with slower gait had higher susceptibility in bilateral inferior frontal, superior temporal, and angular gyri (corrected $p<.0005$). Robust associations were also observed in the middle frontal, precentral, and postcentral gyri of the right hemisphere. These novel findings suggest that reduced myelination or increased iron accumulation in these brain regions may contribute to impaired gait. Future work will need to determine to what extent these cross-sectional QSM metrics are independent predictors of incident adverse health outcomes when controlling for other common brain imaging abnormalities observed in older adults.

DIFFERENTIAL INFLUENCE OF COVID-19 PANDEMIC ON LIFE-SPACE MOBILITY OF OLDER ADULTS

Anna Zisberg,¹ Ksenya Shulyaev,² Nurit Gur-Yaish,³ and Efrat Shadmi,⁴ 1. *University of Haifa, Haifa, HaZafon, Israel*, 2. *Faculty of Social Welfare and Health Science, University of Haifa, Haifa, Hefa, Israel*, 3. *Oranim Academic College of Education, Haifa, HaZafon, Israel*, 4. *University of Haifa, Mount Carmel, Israel, Haifa, Hefa, Israel*

Life-space mobility (LSM) is critical to aging successfully since it is essential to maintain independence, affecting the health and quality of life of older adults. During the COVID-19 pandemic older adults, who are at high-risk of serious illness and complications, are restricted by stay-at-home orders, limiting their outdoor activities. This study evaluated differences in LSM before and during the pandemic and factors related to limited pre-hospitalization mobility. We used a natural experiment design comparing LSM one month

prior to hospitalization and its related factors on two subsamples of hospitalized older adults: recruited before and after February 2020 (pandemic outbreak). No significant differences were observed in LSM between pre-pandemic (N=141, M(SD)=54.9(33,5)) and during-pandemic (N=186, M(SD)=55.3(32.9)) samples, even after adjustment for cognitive, functional, and demographic characteristics ($F=2.281$, $p=0.13$). Of those who participated during the pandemic, a total of 94 (50.5%) declared that their mobility was strongly affected by the pandemic and had significantly lower LSM ($F=4.626$, $p<0.01$) comparing both to those who declared not being affected (N=92) and to the pre-pandemic group, controlling for potential cofounders. In the "during-pandemic" group older adults with higher basic physical functioning, higher economic status, and those with lower levels of education were more likely to indicate that their pre-hospital mobility was affected by the pandemic. These results show that the pandemic period has a differential effect on life-space mobility of older adults. Functional, socio-economic, and educational factors need to be considered in planning how to maintain older adults' mobility during the ongoing pandemic.

DIGITAL MOBILITY ASSESSMENT FOR REGULATORY AND CLINICAL ENDORSEMENT IN HIP FRACTURE PATIENTS

Carl-Philipp Jansen,¹ Kristin Taraldsen,² Hubert Blain,³ and Clemens Becker,⁴ 1. *Robert-Bosch-Hospital Stuttgart, Karlsruhe, Baden-Wurtemberg, Germany*, 2. *Norwegian University of Science and Technology, Trondheim, Sor-Trondelag, Norway*, 3. *Centre Hospitalier Universitaire de Montpellier, Montpellier, Aquitaine, France*, 4. *Robert-Bosch-Hospital, Stuttgart, Baden-Wurtemberg, Germany*

Hip fracture is the most frequent non-intentional injury of older persons leading to hospital admission in Europe and North America. Until recently, in regulatory submissions no attention was given to patients' mobility after sustaining/recovering from a hip fracture. To better evaluate efficacy and effectiveness of new drugs and treatments, it is necessary to develop mobility biomarkers since failure to recover and regain pre-fracture mobility is considered the single most important disability symptom experienced by hip fracture patients, often leading to care home admission. However, regularly used measures of mobility capacity are not representative of individuals' performance in real life, intermittent in nature, and require visiting study centers. Digital technology has the potential to revolutionize mobility assessment in a real-life setting. With this presentation we build a case for a valid solution for real-world digital mobility assessment in hip fracture patients as carried out in the "Mobilise-D" clinical validation study.

DUAL-TASK GAIT SPEED AND MOBILITY ARE POSITIVELY ASSOCIATED WITH DECLARATIVE MEMORY

Michelle Gray,¹ Sally Paulson,² Joshua Gills,¹ Erica Madero,³ Jennifer Myers,³ Anthony Campitelli,¹ Megan Jones,¹ and Jordan Glenn,³ 1. *University of Arkansas at Fayetteville, Fayetteville, Arkansas, United States*, 2. *University of Arkansas at Fayetteville, Cincinnati, Ohio, United States*, 3. *Neurotrack Technologies, Redwood City, California, United States*

In the US, it is not recommended to perform routine screening assessments for cognitive function or impairment among older adults, due to the lack of effective pharmacological treatments. These common practices result in delayed identification and treatments for slowing cognitive decline progression. Thus, the purpose of the present investigation was to determine the ability to predict cognition from common measures of physical function. Seventy-five community-dwelling older adults (80.7 ± 5.4 years) completed physical function and cognitive assessments. Physical function was assessed using the Short Physical Performance Battery (SPPB), peak velocity during a power sit-to-stand task, and dual-task walking test. Cognition (declarative memory) was assessed using a validated Visual Paired Comparison test. 38% of the variance in cognition was accounted for by the predictor variables (age, sex, education, SPPB, dual-task, peak velocity). Significant predictors included dual-task walking ($p = .03$), SPPB ($p = .02$), and education ($p = .02$). For each 1 second faster during the dual-task performance, cognition increased by 4 percentile units. Likewise, each 1 unit increase in SPPB resulted in an increase of 4 percentile points in cognition. The results indicate more than a third of the variance in declarative memory can be predicted by commonly assessed measures of physical function. This information is useful when identifying older adults that may have cognitive impairment before overt signs are realized. With the lack of recommended cognitive testing, using physical function declines to identify possible cognitive decline is promising. These results are preliminary in nature and longitudinal determination is warranted.

EYE AND VISUAL HEALTH IN NEW ENGLAND: FINDINGS FROM THE HEALTHY AGING DATA REPORTS

Shu Xu,¹ Taylor Jansen,² Chae Man Lee,² Maki Karakida,² Frank Porell,³ Elizabeth Dugan,² and Nina Silverstein,⁴ 1. *University of Massachusetts Boston, Dorchester, Massachusetts, United States*, 2. *UMass Boston, Boston, Massachusetts, United States*, 3. *University of Massachusetts Boston, University of Massachusetts Boston, Massachusetts, United States*, 4. *University of Massachusetts Boston, Boston, Massachusetts, United States*

Eye and visual health issues in older adults are prevalent, often undetected and untreated, but can contribute to poor physical and mental health issues, and higher mortality rates. The study describes state and local community rates of eye and visual health indicators (cataract, glaucoma, self-reported vision difficulty, and clinical diagnosis of blindness or visual impairment) of older adults 65+ in MA, NH, RI, and CT. Data sources used to calculate rates were: the American Community Survey (2014-2018 RI, 2012-2016 MA and NH, 2014-2018 CT) and the Medicare Current Beneficiary Summary File (2016-2017 RI, 2015 MA and NH, 2016-2017 CT). Small area estimation techniques were used to calculate age-sex adjusted community rates for more than 150 health indicators (<https://healthyagingdatareports.org/>). Disparities in rates were examined for 4 eye and visual health indicators: cataract, glaucoma, self-reported vision difficulty, and clinical diagnosis of blindness or visual impairment. Results showed variability in rates across states. MA had the highest rates of self-reported vision difficulty (5.8%) and blindness

or visual impairment (1.5%), and the greatest differences in rates of self-reported vision difficulty (0.00-40.91%). CT had the highest rates of glaucoma (28.3%), and the greatest differences in rates of glaucoma (19.51-41.91%) and blindness or visual impairment (0.44-4.39%). RI had the highest rates of cataract (67.5%). Understanding the distribution of community rates makes disparities evident, and may help practitioners and policymakers to allocate resources to areas of highest need.

METABOLIC SYNDROME AND OBJECTIVE PHYSICAL PERFORMANCE MEASURES IN MID-TO-EARLY LATE LIFE WOMEN: SWAN

Elsa Strotmeyer,¹ Robert Boudreau,¹ Brittney Lange-Maia,² Samar El Khoudary,¹ Kelly Ylitalo,³ Andrea Kriska,¹ Carrie Karvonen-Gutierrez,⁴ and Jenna Napoleone,¹ 1. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*, 2. *Rush University Medical Center, Chicago, Illinois, United States*, 3. *Baylor University, Waco, Texas, United States*, 4. *University of Michigan, School of Public Health, Ann Arbor, Michigan, United States*

Metabolic syndrome (MetS) is a cluster of factors (hypertension, abdominal obesity, impaired fasting glucose, low high-density lipoprotein, hypertriglyceridemia). How midlife MetS impacts future physical functioning is uncertain. We hypothesized that higher midlife MetS components are associated with poorer physical performance in early late life for multi-ethnic women. MetS status from 1996-2011 (8 visits) and objective physical performance (2015/16; short physical performance battery (SPPB; 0-12), 40-foot walk (m/s), 4-meter gait speed (m/s), chair stands (sec), stair climb (sec)) were assessed in the Study of Women's Health Across the Nation (SWAN; n=1722; age 65.4±2.7 years; 26.9% Black, 10.1% Chinese, 9.8% Japanese, 5.5% Hispanic). Poisson latent class growth modeling identified trajectory groups distinguishable by number of MetS components: none (23.9%), 1=low-MetS (28.7%), 2=mid-MetS (30.9%), >3=high-MetS (16.5%). High-MetS versus none had higher body mass index, pain, financial strain, and lower physical activity and self-reported health (p < 0.0001). Black and Hispanic women were more likely to be in high-MetS and had worse physical functioning, along with Chinese women, versus White (all p<0.05, except gait speed in Hispanic). Adjusted linear regression related MetS groups to physical performance. High-MetS versus none demonstrated adjusted worse 40-ft walk (β:-0.08; 95% CI:-0.13, -0.03), gait speed (β:-0.09; 95% CI:-0.15, -0.02), SPPB (β:-0.79; 95% CI: -1.15, -0.44), and chair stands (β:0.69; 95% CI: 0.09, 1.28), but not stair climb, with race significantly related to all except 40-ft walk. Midlife MetS trajectories related to poor physical performance in early late life multi-ethnic women. Managing midlife metabolic function may improve physical performance in late life.

MOBILIZING ELDERLY: AN INTERPROFESSIONAL EFFORT

David Lynch,¹ Andrew de la Paz,² Carissa Lau,² Kimberly Mournighan,² Kimberly Young,³ Maureen Dale,³ Laura Hanson,³ and John Batsis,⁴ 1. *University of North Carolina, Chapel Hill, North Carolina, United States*, 2. *UNC, Chapel Hill, North Carolina, United States*, 3. *University of North Carolina, University of North*

Carolina, North Carolina, United States, 4. *University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States*

Older adults often experience functional decline during hospitalization as a result of immobility. Such decline has associated adverse outcomes, including gait instability, falls, pressure injuries, delirium, and new nursing home admissions. Our objective was to create an effective and sustainable in-hospital mobility program through enhanced interdisciplinary cooperation in an Acute Care of the Elderly (ACE) unit. An interdisciplinary team at UNC's 25-bed ACE unit planned and delivered enhanced patient mobility beginning in July 2020. We used an input-process-output model to design and analyze an intervention based on enhanced collaboration. Inputs included a mobility taskforce which was comprised of physicians, nurses, physical and occupational therapists, and quality improvement specialists. Through regular meetings, each taskforce member contributed to the study design and were empowered to identify barriers to implementation. Outputs included stakeholder engagement and mobility rates. Early results show a doubling in mobility rates over a 6-month period with consistent and enthusiastic stakeholder engagement. Observations of such benefits include: a) stakeholder inclusion from each discipline ensured implementation that was pragmatic and easily incorporated into the daily workflow; b) mobility champions regularly disseminated information to their respective disciplines, leading to changes using a quality improvement process; and c) barriers to implementation were rapidly identified, and mobility champions were motivated to find solutions, allowing cohesive incorporation of a broad spectrum of priorities. An interprofessional team model is effective to mobilize hospitalized older adults, potentially reducing adverse hospital outcomes. Successful implementation of such programs is dependent on interprofessional collaboration.

MODERATORS OF DUAL TASK GAIT EFFECTS IN MILD COGNITIVE IMPAIRMENT AND DEMENTIA

Edward Ofori,¹ Dara James,² Olivia Kaczmarek,³ and Mark Gudesblatt,⁴ 1. *ASU, Arizona State University, Arizona, United States*, 2. *Arizona State University, Phoenix, Arizona, United States*, 3. *SouthShore Neurologic, Southshore Neurologic, New York, United States*, 4. *South Shore Neurologic, Islip, New York, United States*

Spatiotemporal gait parameters may provide indication about the cognitive status of individuals. Dysfunction in specific gait features has been associated with increased risk of cognitive decline. Here we use spatiotemporal gait patterns to determine whether specific cognitive domain scores moderate the effects during dual-tasking on individuals with mild cognitive impairment (MCI) and dementia. Participants (n=46; mean age: 77.0±8.9 years) with a diagnosis of cognitive impairment (n=16), or dementia (n=30) were included. They performed validated computerized cognitive assessment battery (CAB, NeuroTrax BrainCare) to obtain cognitive domain measures of executive function (EF), attention, memory, visual-spatial processing (VSP), information processing speed (IPS), and a global cognitive score (GCS) measure. Using the Zeno Walkway Gait Analysis System (Protokinetics), measures of velocity, stride width (SW), stride time (ST), stride length, cadence, double support (DS),

and gait variability were obtained for both single-task and DT gait. Data analysis was conducted using SPSS 26 and PROCESS 3.5. As expected, the dementia group had lower cognitive domain scores and slower walking speed than MCI group. Results also indicated that visual-spatial processing skills was the only cognitive domain that did have a moderation effect on gait velocity ($F=4.2$, $p<0.05$, R-square change 10%). Our results indicate that differences between walking speed in MCI and dementia groups are moderated by visual spatial skills. Improvement in visual spatial skills could improve the dual task effects of individual gait measures.

PERSISTENT DISABILITY SIX MONTHS AFTER INITIAL DISABILITY LESS LIKELY IN OLDER WOMEN

Raj Shah,¹ Katherine Webb,² Joanne Ryan,² Rory Wolfe,² Michael Ernst,³ Sara Espinoza,⁴ and Robyn Woods,² 1. *Rush, Rush University Medical Center, Illinois, United States*, 2. *Monash University, Melbourne, Victoria, Australia*, 3. *University of Iowa, Iowa City, Iowa, United States*, 4. *University of Texas Health Science Center San Antonio, San Antonio, Texas, United States*

Many community-dwelling older adults develop activity of daily living (ADL) disability and subsequently regain function. Using data from the ASPirin in Reducing Events in the Elderly (ASPREE) clinical trial, we examined the relationship of gender, incident disability, and persistent disability 6 months after the incident disability. Walking, bathing, dressing, transferring, toileting, and eating were assessed as ADLs, at bi-annual interviews. ADL disability was defined as requiring help with or inability to do or severe difficulty with ≥ 1 ADL; persistent disability was an ADL loss at 6 months after a first (incident) ADL disability. Discrete time, multivariable Cox proportional hazards regression was utilized to estimate associations with developing incident ADL disability described as cause-specific hazard ratios, with death as a competing outcome. For persons with incident ADL disability, odds of developing persistent disability at 6 months as compared to recovery was determined using multivariable logistic regression. These analyses included 18,414 (51.6% women) ASPREE participants in the United States and Australia aged 70+ years (65+ years if U.S. ethnic minority) without ADL disability at trial entry. During a median follow-up of 4.7 years, 1,485 participants (63.2% women) developed an incident ADL disability, and, of those, 272 (57.0% women) met criteria for persistent disability at 6 months. Women had an increased risk ($HR=1.17$, 95% $CI=1.05$ to 1.32) of developing incident ADL disability; however, women were less likely to have persistent disability versus recovery 6 months later ($OR=0.66$, 95% $CI=0.49$ to 0.89). Why persistent disability development is lower in older women needs further exploration.

PHYSICAL FUNCTION TRANSITIONS AND HEALTHCARE UTILIZATION AMONG OLDER MEXICAN AMERICANS.

Amy Givan, Lin-Na Chou, Yong-Fang Kuo, and Soham Al Snih, *University of Texas Medical Branch, Galveston, Texas, United States*

The aim of this study was to examine the relationship between 2-year physical function transitions and one-year healthcare utilization among Mexican American Medicare

beneficiaries. The sample consisted of 429 Mexican Americans ≥ 75 years old from the Hispanic Established Population for the Epidemiologic Study of the Elderly linked with Medicare claims data from the Centers for Medicare and Medicaid Services. Short Physical Performance Battery (SPPB) from Wave 5 (2004/05) to Wave 6 was used to create physical function transition groups. The outcomes were physician visits (<6 , $6-12$, >12 visits), number of emergency room visits, and number of acute hospitalizations one-year after physical function transitions. Multinomial logistic regression and Generalized Estimating Equation with negative binomial distribution were used to estimate the odds ratio of healthcare utilization as a function of physical function transition groups, controlling for socio-demographics and comorbidities. Participants who improved or remained moderate-high physical function had lower odds ratio (OR) of being hospitalized (0.40, 95% Confidence Interval [CI]=0.18, 0.90) or visiting the emergency room (OR=0.52, 95% CI=0.32-0.84) one-year later compared to participants who remained in the low physical function group. No difference in physician visits across physical function transition groups was found. This study showed healthcare utilization differed by physical function transition groups among Mexican American Medicare beneficiaries. Physical function improvement or maintenance of moderate-high physical function should be targeted in older Mexican Americans, a population at great risk of developing disability, to reduce or delay dependency and healthcare burden.

RELATIONSHIP BETWEEN CLUSTERS OF CHRONIC CONDITIONS AND DISABILITY TRAJECTORIES

Tara Klindinst, Lauren Terhorst, and Julieen Rodakowski, *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Recent evidence shows that more complex clusters of chronic conditions are associated with poorer health outcomes. Less clear is the extent to which these clusters are associated with different types of disability (basic and instrumental activities of daily living (ADL, IADL) and functional mobility (FM)) over time. This was a longitudinal analysis using the National Health and Aging Trends Study (NHATS) ($n = 6,179$). Using latent class analysis, we determined the optimal clusters of chronic conditions, then assigned each person to a best-fit class. Next, we used mixed-effects models with repeated measures to examine the effects of group (best-fit class), time (years from baseline), and the group by time interaction on each of the outcomes in separate models over 4 years. We identified 5 chronic condition clusters: “multisystem morbidity” (13.9% of the sample), “diabetes” (39.5%), “osteoporosis” (24.9%), “cardio/stroke/cancer” (4.5%), and “minimal disease” (17.3%). Group by time interaction was not significant for any outcome. For ADL outcome, only time was significant ($F_{3,16249} = 224.72$, $p < .001$). For IADL, both group ($F_{4,5403} = 6.62$, $p < .001$) and time ($F_{3,22622} = 3.87$, $p = .009$) were significant. For FM, both group ($F_{4,5920} = 2.96$, $p = .02$) and time were significant ($F_{3,16381} = 213.41$, $p < .001$). We did not find evidence that any cluster experienced greater increases in disability over time, but all clusters containing multiple chronic conditions had risk of IADL and FM disability. Increased screening for IADL and FM disability could identify early disability and prevent decline.

RISK FACTORS OF WALKING WHILE TALKING DECLINE IN OLDER ADULTS: CENTRAL CONTROL OF MOBILITY AND AGING STUDY

Oshadi Jayakody,¹ Helena Blumen,² Emmeline Ayers,² and Joe Verghese,² 1. *Albert Einstein College of Medicine, The Bronx, New York, United States*, 2. *Albert Einstein College of Medicine, New York, New York, United States*

Background: Slow gait speed during walking while talking (WWT-speed) is associated with an increased risk of falls and dementia. Age-related changes in WWT-speed and associated risk factors, however, are poorly understood. This study examined 1) change in WWT-speed over time 2) factors associated with change in WWT-speed. Methods: A total of 431 older participants (M Age=76.8±6.4 years; M follow-up 4.5±2.3 years) enrolled in the Central Control of Mobility in Aging study were examined. WWT-speed was measured with a computerized walkway while participants recited alternate letters of the alphabet while walking. The following baseline measures were examined as risk factors: demographic [age, sex, education], medical [hypertension, diabetes, cardiac arrhythmias, history of stroke, Parkinson's disease, kidney disease, arthritis, depression], cognitive [global cognition, executive function, processing speed], sensorimotor [balance, grip strength, vision], falls and frailty. Linear mixed effect models were used to examine 1) change in WWT-speed over time 2) risk factors of WWT-speed change. Results: WWT-speed declined over time (b -1.06, 95%CI -1.45, -.68) independent of baseline age, sex and education. Rate of WWT-decline was modified by age (b -.10, 95%CI -.17, -.03) and poorer balance (b -1.12, 95%CI -1.95, -.28). Lower scores in tests of global cognition and processing speed and, kidney disease predicted slow WWT-speed on average. Conclusion: Greater age and poorer balance accelerate WWT-speed decline while poorer global cognition, slow processing speed and kidney disease predicts slow WWT-speed. These factors may provide potential targets for future interventions to prevent decline in WWT-speed and associated adverse health outcomes.

UTILITY OF THE LATE LIFE FUNCTION AND DISABILITY INSTRUMENT (LLFDI) IN REHABILITATION SERVICES FOR OLDER ADULTS

Pamela Toto,¹ and Anne Stankiewicz,² 1. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*, 2. *Capable Care Solutions LLC, Lancaster, Pennsylvania, United States*

Introduction: The Late Life Function and Disability Instrument (LLFDI) is a valid self-report tool that quantifies disability based on activity limitations and participation restrictions in everyday life. Both the original longer tool (LLFDI) and the shorter computer adaptive version (LLFDI-CAT) offer practitioners a method for measuring function independent or in conjunction with performance-based assessment. Objectives: Examine scores of the LLFDI and LLFDI-CAT for measuring disability in older adults who are receiving rehabilitation services in community and institution settings. Method: A secondary data analysis was conducted comparing scores from occupational therapy evaluations with older adults from 3 groups: 1) older adults in primary care using the LLFDI; 2) older adults in primary care using the LLFDI-CAT; older adults in a skilled nursing facility (SNF) using the LLFDI-CAT. Results: Mean scores for Activity Limitation and Participation Restriction were

lowest for older adults in a SNF indicating greater disability. A one-way Analysis of variance on ranks showed a main effect for Activity Limitation, $\chi^2(2) = 22.267$, $p < 0.001$, and Participation Restriction, $\chi^2(2) = 60.372$, $p < 0.001$. Post-hoc analyses revealed significant differences between groups based on tool (i.e. LLFDI vs. LLFDI-CAT) for Activity Limitations and setting (i.e. primary care vs. SNF) for Participation Restriction. Conclusion: The LLFDI-CAT may be the preferred instrument to measure disability in older adults across treatment settings. Additional research is warranted to understand how personal and environmental factors influence LLFDI-CAT outcomes.

Session 9395 (Poster)

Multidimensional Aspects of Long-Term Care

CULTIVATING A PATIENT-CENTERED ENVIRONMENT (CAPE): RENOVATIONS IN LONG-TERM CHRONIC CARE

Elizabeth Howard,¹ and Tammy Retalic,² 1. *Boston College, Dover, Massachusetts, United States*, 2. *Hebrew SeniorLife, Boston, Massachusetts, United States*

Achieving institutional goal of full, person-centered care was encumbered by an outdated structural "hospital model" at one long-term care facility that undertook building renovations, transforming long hallways into "neighborhood" of compact households. Quality of Life Survey and Long-term Care Minimum Data Set generated data at baseline and 1-year follow-up, comparing renovated(RU) and non-renovated unit(NRU) residents (n=36) to evaluate achievement of person-centered care. RU residents indicating they could "eat when I want" increased 75% to 81% at follow-up and decreased 17% for NRU residents. Sixty-seven percent of RU residents reported bathing "when they want" in contrast to 40% of NRU residents. Most RU residents agreed, "staff act on my suggestions." More RU residents (68% vs 53%) agreed: "I spend time with other like-minded residents" and more RU residents (86% vs 43%) reported opportunity to explore new skills, interests. RU residents more often reported (50% vs 37%) "people ask for my help or advice." Similar differences were observed with "it is easy to make friends here," 67% RU residents responding affirmatively. RU residents reporting "feeling down" improved, moving from 46% to 50% disagreeing with this item with while increased number of NRU residents (18% to 22%) reported "feeling down" at follow-up. Improvement with independent performance of bed mobility, transfer, walking, and dressing among RU residents was observed while NRU residents had decreased percentages of independence. Evaluation of resident outcomes demonstrated improvement with personal choice, activities, personal relationships, functional independence and mood. Physical unit renovations appear to enhance implementation of person-centered care model.

DO DAYTIME ACTIVITY, MOOD AT BEDTIME AND UNIT TUMULT PREDICT NIGHTTIME SLEEP QUALITY OF LONG-TERM CARE RESIDENTS?

Murad Taani,¹ and Christine Kovach,² 1. *University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, United States*, 2. *University of Wisconsin Milwaukee, Milwaukee, Wisconsin, United States*

Sleep quality declines in old age and is particularly poor for long-term care (LTC) residents with dementia. Compromised sleep quality is associated with severe cognitive and neuropsychiatric symptoms, agitation, aggressiveness, and poor quality of life. Based on the premise that stressors can have a cumulative effect on people with dementia throughout the day that contributes to negative consequences later in the day, we examined if daytime activity, mood, and unit tumult were associated with sleep quality. A convenience sample of 53 LTC residents with dementia participated in this correlational study. Objective sleep quality and activity variables were measured using Actigraphy, and mood was measured by the Observed Emotion Rating Scale. Unit tumult was defined as events in the residents living area that are deviations from the typical day (i.e., census changes, being cared for by a certified nursing assistant from a temporary staffing agency, and lower than usual staffing level). Comorbid illness and level of dementia were control variables. Half of the sample had a sleep efficiency that was less than .85 and were awake for more than 90 minutes at night. Comorbid illness, negative mood at bedtime, and daytime activity level accounted for 26.1% of the variance in total sleep minutes. Census changes and the use of temporary agency staff were associated with poor total sleep time and sleep efficiency. Findings suggest that daytime activity, mood at bedtime, and unit tumult should be considered when designing and testing interventions to improve sleep quality among LTC residents with dementia.

FACTORS INFLUENCING RETENTION INTENTION OF NURSES AT LONG-TERM CARE HOSPITALS IN KOREA

So Young Shin,¹ and Joo Hee Kim,² 1. *Global Brain Health Institute, University of California, San Francisco / Inje University, Busan, Pusan-jikhalsi, Republic of Korea*, 2. *Busan Hangun Hospital, Busan, Pusan-jikhalsi, Republic of Korea*

Purpose: This study aimed to investigate the levels and correlations of role conflict, nursing professionalism, nursing work environment and retention intention, and the factors influencing retention intention of nurses at long-term care hospitals. **Methods:** The subjects included 183 nurses at nine long-term care hospitals in one metropolitan city in Korea. A set of self-reported questionnaires was administered to assess general characteristics, role conflict, nursing professionalism, nursing work environment, and retention intention of the subjects. Collected data was analyzed using descriptive statistics, t-tests, one-way ANOVA, Pearson correlation coefficients, and multiple linear regression. **Results:** 183 subjects with a mean (\pm SD) age of 41.66 (\pm 12.29) years were included in the final analyses. Retention intention had a significant positive correlation with nursing professionalism ($r=.39$, $p<.001$) and nursing work environment ($r=.51$, $p<.001$). Nursing work environment had a significant negative correlation with role conflict ($r=-.30$, $p<.001$) and a significant positive correlation with nursing professionalism ($r=.48$, $p<.001$). In the final multiple regression analysis, the factors influencing retention intention of subjects were number of beds ($\beta=-.15$, $p<.026$), nursing professionalism ($\beta=.19$, $p=.007$) and nursing work environment ($\beta=.36$, $p<.001$). The explanatory power of number of beds, nursing

professionalism and nursing work environment on retention intention was 34.0% ($F=16.66$, $p<.001$). **Conclusion:** Improving nursing professionalism and nursing work environment of nurses at long-term care hospitals will ultimately enhance their retention intention and positively impact on the quality of gerontological nursing service.

FAILURE TO THRIVE: NURSING HOME STAFF EXPERIENCES IN CARING FOR RESIDENTS DURING THE COVID-19 PANDEMIC

Yu-Ping Chang,¹ Audrianna Raciti,² Cristina de Rosa,¹ Margaret Doerzbacher,¹ Yanjun ZHou,¹ Chia-Hui Chen,¹ and Amy Lyons,¹ 1. *University at Buffalo, Buffalo, New York, United States*, 2. *University at Buffalo, 7168292015, New York, United States*

Nursing home residents and staff have accounted for roughly 40% of Coronavirus-related deaths in the U.S. The burden of caring for vulnerable residents coupled with isolation policies has taken a significant emotional toll among direct health care staff in long term care facilities. This study explores nursing home staff's experiences in caring for residents during the COVID-19 pandemic. A qualitative descriptive approach with a semi-structured guide was used to conduct individual interviews. We recruited nursing home staff employed during the COVID-19 pandemic in long term care facilities located in New York State. Interviews were recorded, transcribed verbatim, and then analyzed using Braun and Clarke's Reflexive Thematic analysis. Twelve nursing home staff were interviewed. Participants consistently refer to failure-to-thrive as an extremely concerning problem because many residents demonstrate decreased appetite and poor nutrition, inactivity, and depressive symptoms due to social isolation. They also often feel frustrated and overwhelmed due to uncertainty and shortages of staff. Five main themes were identified, including doing their best to manage residents' failure-to-thrive, working as a team, keeping family members informed and connected, struggling to balance competing personal and professional demands, and needing support to reduce stress and build strength. Our study findings indicate that nursing home staff experienced a high level of stress and identified failure-to-thrive caused by isolation and loneliness as a common phenomenon among nursing home residents during the COVID-19 pandemic. Interventions are urgently needed to reduce isolation and loneliness in nursing home residents and to provide support for staff.

HUMAN CAPITAL AND EMPLOYMENT OUTCOMES AMONG FOREIGN EDUCATED AND US NURSES WORKING IN LONG TERM CARE

Roy Thompson,¹ Susan Silva,¹ Kirsten Corazzini,² Thomas Konrad,³ Michael Cary, Jr.,¹ and Eleanor McConnell,⁴ 1. *Duke University, Durham, North Carolina, United States*, 2. *University of Maryland School of Nursing, Baltimore, Maryland, United States*, 3. *University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States*, 4. *Duke University School of Nursing, Durham, North Carolina, United States*

Employing Foreign Educated Nurses (FENs) helps address Registered Nurse (RN) shortages in long-term care (LTC) in the United States (US). However, examination of factors explaining differences in their employment outcomes relative

to US Educated Nurses (USENs) is limited. This study uses 2018 National Sample Survey of Registered Nurses data to compare income, work hours, job satisfaction, and human capital, defined as personal characteristics (knowledge, work experience) and behaviors (job mobility), of FENS and USENs working full-time in LTC. A human capital score, consisting of highest nursing education, skill certifications, state licensures, years of experience, multi-state employment history, and multi-lingual status was constructed. Covariates included nurse demographics, direct care role, and ability to practice to full scope. Covariate-adjusted group differences in employment outcomes and human capital were compared using ANCOVA and logistic regression. Mediation analyses explored whether human capital explained FEN vs USEN differences. FENs earned higher hourly wages ($p=0.0169$), worked fewer hours annually ($p=0.0163$), and reported greater human capital ($p<.0001$) compared to USENs. FENs and USENs, however, had similar annual salaries ($p=0.3101$) and job satisfaction ($p=0.1674$). Human capital mediated FEN vs USEN effects on hourly wages but not annual work hours. FENs' higher levels of human capital partially account for FEN vs USEN differences in hourly wages. Application of the human capital concept advanced our ability to examine differences in employment outcomes and highlight aspects of the value that FENs contribute to LTC settings.

INDICATORS OF ELDER MISTREATMENT: CORRELATES AMONG VETERANS RECEIVING CARE IN THE VETERANS HEALTH ADMINISTRATION

Jenefer Jedele,¹ Cameron Griffin,² and Julie Weitlauf,³ 1. *Veterans Health Administration, Ann Arbor, Michigan, United States*, 2. VA, *Ann Arbor, Michigan, United States*, 3. *VAPAHCs/Stanford, Palo Alto, California, United States*

Among community-dwelling adults ages 65 and older, approximately 11% have experienced elder mistreatment (EM), including physical, emotional or sexual abuse, neglect, or financial exploitation. EM research typically focuses on this age group; however, Veterans receiving Veterans Health Administration (VHA) care have increased earlier morbidity, which may accelerate the impacts of EM. Using a cohort of all VHA Veterans 50 years and older with VHA use in 2018-2020, we examined correlates of EM. ICD-10 codes from clinical encounters identified Veterans with indications of EM ($n=4,427$). A 10% sample of Veterans without indications of EM was selected for comparison ($n=530,535$). Logistic regression compared EM+ Veterans to the comparison sample and assessed overall demographic and clinical differences as well as differences by age, i.e. 50-64 versus 65 and older. Overall, female gender (OR=5.3, 95% CI=4.3-6.5), non-white race/ethnicity (OR=1.7, CI=1.5-1.9), dementia (OR=3.0, CI=2.6-3.5), PTSD (OR=2.0, CI=1.6-2.5), anxiety (OR=1.3, CI=1.0-1.5), military service connected disability status (OR=1.3, CI=1.1-1.5), and higher Elixhauser medical morbidity scores (OR=1.1, CI=1.1-1.1) were associated with EM. Prior year ER visits (OR=28.0, CI=23.6-33.4), inpatient stays (OR=14.0, CI=11.5-17.0), and mental health visits (OR=26.1, CI=22.2-30.6) also predicted EM+ status. Forty-six percent of VHA Veterans with indicators of EM were aged 50-64. For these Veterans, female gender, PTSD, service connection, and mental health visits were associated with increased risk of EM compared to Veterans 65+. Findings

highlight clinical correlates of EMs among Veterans in VHA care. Increased awareness of EM risk factors is warranted and may inform VHA efforts for EM prevention, detection and intervention.

LIVING IN THE NEW NORMAL: EFFECT OF RESIDENTIAL SETTING ON PERCEPTION OF A MEANINGFUL LIFE AMONG OLDER WOMEN

Judith Scott,¹ Helen Graham,¹ Ann Mayo,² and Melissa Benton,¹ 1. *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*, 2. *University of San Diego, San Diego, California, United States*

Perception of a meaningful life is related to depression, anxiety, and general well-being. The sense that one's life is meaningful influences overall quality of life, which influences aging well. It is not clear whether differences in residential setting influence perception of a meaningful life. This study evaluated the effect of residential setting (community versus assisted living) on perception of a meaningful life in 48 older (79.7 ± 1.0 years) women living in the community ($n=24$) or assisted living ($n=24$) who were pair matched by age. They completed a one-time questionnaire regarding self-rated health and whether life has meaning. Both questions were scored on a 5-point scale with 0 indicating poor health or no life meaning and 4 indicating excellent health or strong life meaning. There were no significant differences in age between women in community living (CL) and assisted living (AL) (78.0 ± 09 vs. 81.5 ± 1.6 years, respectively; $p=0.7$). Both groups also reported similar self-rated health scores (CL: 2.4 ± 0.2 ; AL: 2.2 ± 0.2 ; $p=0.4$), indicating good-very good health. However, there were significant differences between groups in their perception of a meaningful life. Women in CL reported significantly lower scores compared to women in AL (2.9 ± 0.2 vs. 3.6 ± 0.1 ; $p=0.006$), indicating that women in CL perceived a less meaningful life. Based on our findings, it appears that the supportive infrastructure provided by AL residential settings may promote quality of life and successful aging by enhancing the perception of a more meaningful life.

NURSING HOME FACTORS AND THEIR IMPACT ON COVID-19 CASES: A STUDY OF WISCONSIN STATE

Mohammed Abahussain,¹ Priya Nambisan,² Colleen Galambos,² Bo Zhang,² and Elizabeth Bukowy,³ 1. *University of Wisconsin- Milwaukee, Wauwatosa, Wisconsin, United States*, 2. *University of Wisconsin- Milwaukee, Milwaukee, Wisconsin, United States*, 3. *Medical College of Wisconsin, Wauwatosa, Wisconsin, United States*

COVID-19 has been devastating for Nursing Homes (NHs). The concentration of older adults with underlying chronic conditions inevitably made the setting highly vulnerable leading to high rates of mortality for residents. However, some nursing homes fared better than others. This study examines several quality measures and organizational factors to understand whether these factors are associated with COVID-19 cases in Wisconsin. We combined three datasets from Centers for Medicare & Medicaid Services (CMS) – the Star Rating dataset, Provider Information dataset and COVID-19 Nursing Home dataset. Data used

is from the period of Jan 1 – Oct 25, 2020 for the state of Wisconsin. The analysis includes 331 free-standing NHs with no missing values from the data sets. The variables used were self-reported information on nursing home ratings, staff shortage, staff reported hours, occupancy rate, number of beds and ownership. Of the 331 NHs examined, shortages were reported of 25.4%, 31.1%, 3.2% and 15.6% of licensed nurse staff (25.4%), nurse aides (31.1%), clinical staff, (3.2%) and other staff (15.6%) Additionally, there was a significant ($p < .05$) positive correlation between number of beds and COVID-19 cases, and there was no statistically significant association between occupancy rate and COVID-19 cases. NHs with better star ratings were also found to have less COVID-19 cases. Interestingly, private NHs had significantly higher COVID-19 cases than for-profit and government owned NHs, a finding that is congruent with other studies in this area. Recommendations for practice will be discussed.

POTENTIAL SOURCES OF RACIAL AND ETHNIC DISPARITIES IN NURSING HOME INFLUENZA VACCINATION

Melissa Riester,¹ Elliott Bosco,¹ Barbara Bardenheier,² Patience Moyo,³ Rosa Baier,¹ Melissa Eliot,¹ and Andrew Zullo,¹ 1. *Brown University, Providence, Rhode Island, United States*, 2. *Brown University School of Public Health, Smithfield, Rhode Island, United States*, 3. *Brown University School of Public Health, Providence, Rhode Island, United States*

Racial and ethnic disparities in influenza vaccination among nursing home (NH) residents are well-documented and have persisted over time, suggesting that new strategies are necessary to reduce disparities. We conducted a retrospective cohort study to examine the degree to which observable characteristics drove influenza vaccination disparities. We linked Minimum Data Set (MDS) assessments to facility-level data for short- and long-stay NH residents aged ≥ 65 years. We included residents with six-month continuous enrollment in Medicare and an MDS assessment during the influenza season (October 1, 2013 through March 31, 2014). Using nonlinear Oaxaca-Blinder decomposition, we decomposed the disparities in vaccination between White versus Black and White versus Hispanic residents. We analyzed short- and long-stay residents separately. Our study included 630,373 short-stay and 1,029,593 long-stay residents. Among short-stay residents, 67.2% of Whites, 55.1% of Blacks, and 54.5% of Hispanics were vaccinated against influenza; among long-stay residents, 84.2% of Whites, 76.7% of Blacks, and 80.8% Hispanics were vaccinated against influenza. Across the four comparisons, the crude disparity in influenza vaccination ranged from 3.4-12.7 percentage points. By equalizing 27 characteristics, these disparities could be reduced by 37.7%-59.2%. Living in a predominantly White facility and proxies for NH quality were important contributors to the disparity, although characteristics unmeasured in our data (e.g., NH staff attitudes and beliefs) contributed 40.8%-62.3% to the disparity across comparisons. Intervening on factors associated with NH quality may reduce racial/ethnic disparities in influenza vaccination. Qualitative research is essential to explore potential contributors not captured in our administrative data.

RACIAL AND ETHNIC DISPARITIES IN PAIN MANAGEMENT FOR NURSING HOME RESIDENTS: A SCOPING REVIEW

Cassandra Dictus,¹ Youngmin Cho,² Tamara Baker,³ and Anna Beeber,⁴ 1. *School of Nursing, University of North Carolina - Chapel Hill, North Carolina, United States*, 2. *University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States*, 3. *University of North Carolina, Chapel Hill School of Medicine, University of North Carolina at Chapel Hill (School of Medicine), North Carolina, United States*, 4. *University of North Carolina at Chapel Hill, UNC Chapel Hill, North Carolina, United States*

Within nursing homes, residents commonly experience pain that unfortunately goes underrecognized and undertreated, having a dramatic negative impact on residents' quality of life. Nursing homes are becoming more racially and ethnically diverse, and there is concerning evidence documenting disparities in the quality of nursing home care. In other healthcare settings, people of diverse race groups often receive less optimal pain management, but the evidence regarding racial disparities has not been synthesized for nursing homes. Thus, the purpose of this review was to investigate what is known about racial disparities related to pain management (e.g. assessment, treatment, preferences) in US nursing homes. We completed a scoping literature review using PRISMA-ScR guidelines and searching PubMed, CINAHL, and Scopus for peer-reviewed, empirical studies. Most studies were older large retrospective cohort studies of administrative data documenting that White residents were more likely than residents of diverse race groups to have pain documented and treated. Only a few studies looked at possible reasons to explain the disparities; differences were not found to be related to nursing staff racial bias nor differences in pain-related diagnoses. However, there was evidence of racial differences in resident behavior and attitudes related to pain management. None of the studies examined systemic factors related to differences among nursing homes, which has been implicated in studies looking at other outcomes including COVID-19. More research is needed which examines the causal mechanisms behind the documented racial disparities in pain management so that gaps in care can be reduced.

SPIRITUALITY AS AN ESSENTIAL ELEMENT OF PERSON-CENTERED CARE

Rachel Nathan,¹ Deborah Zuercher,² Steven Eveland,³ Anjana Chacko,³ and Raya Kheirbek,⁴ 1. *University of Maryland School of Medicine, University of Maryland, Maryland, United States*, 2. *University of Maryland Medical Center, University of Maryland, Maryland, United States*, 3. *University of Maryland, Baltimore, Maryland, United States*, 4. *University of Maryland School of Medicine, University of Maryland School of Medicine, Maryland, United States*

Data demonstrate that the majority of patients with serious or chronic illness would like their clinicians to address their spirituality but that the majority of clinicians do not provide such care. Reasons cited include lack of training. Palliative Medicine, built on the biopsychosocial-spiritual model of care, has long recognized the critical role of spirituality

in the care of patients with complex, serious, and chronic illness. There is mounting evidence that spiritual care is a fundamental component of all high-quality compassionate health care, and it is most effective when it is recognized and reflected in the attitudes and actions of both patients and health care providers. We conducted focus groups as a first step in the process to arrive at a consensus definition of “spiritual care.” A second step involved collecting and comparing frameworks and models that recognize that providers cannot be made compassionate simply through the imposition of rules; methods were needed to achieve behavior change. The study group developed and piloted curriculum to train health care providers. The created curricula covered the definitions of a spiritual care, self-awareness, cultural sensitivity, assessment, and skills. As part of ongoing curriculum development processes, training included evaluation tools to accompany skill development. Our work demonstrated the need for compassionate presence during encounters, for applying the spirituality in professional life; and for identifying ethical issues in inter-professional spiritual care. We concluded that it is feasible to train clinicians to address spirituality and provide holistic and patient-centered care in an effort to minimize suffering.

TECHNOLOGIES AND THE EFFECTS ON SOCIAL ENGAGEMENT IN LONG-TERM CARE FACILITIES DURING COVID-19: A SCOPING REVIEW

Timothy Wood,¹ Shannon Freeman,² and Alanna Koopmans,³ 1. *University of Northern British Columbia, Canmore, Alberta, Canada*, 2. *University of Northern British Columbia, Prince George, British Columbia, Canada*, 3. *UNBC, University of Northern British Columbia, British Columbia, Canada*

During the COVID-19 pandemic, the sense of loneliness and social isolation felt by older adults in long-term care facilities has been exacerbated. Although there has been an increase in the number of digital solutions to mitigate social isolation during COVID-19, facilities in northern British Columbia do not have sufficient information regarding the technologies to support social connectedness. To support evidence-based policy decisions, a scoping review was conducted to identify existing virtual technology solutions, apps, and platforms that promote social connectedness among older adults residing in long-term care. A combination of keywords and subject headings were used to identify relevant literature within PubMed, CINAHL EBSCO, PsychINFO EBSCO, Embase OVIDSP, and Web of Science ISI databases. DistillerSR was used to screen and summarize the article selection process. Twenty-three articles were identified for full-text analysis. A variety of technologies are described which can be used to mitigate the impacts of social isolation felt by long-term care residents. However, many of these digital solutions require stable high-speed internet. This remains a challenge for facilities in northern areas as many have limited access to reliable internet. Metrics used to evaluate social engagement in the context of long-term care are also outlined. This research provides the preliminary groundwork necessary to better inform policy decisions about which technologies are available and, of these, which are effective at enhancing social connectedness for older adults in long-term care.

TECHNOLOGY GUIDED ASSESSMENT FOR URINARY TRACT INFECTION: CREATING A COMMON INTERPROFESSIONAL LANGUAGE

Donna Owen,¹ Alyce Ashcraft,² Kyle Johnson,² Huaxin Song,² and John Culberson,² 1. *Texas Tech University Health Sciences Center, Houston, Texas, United States*, 2. *Texas Tech University Health Sciences Center, Lubbock, Texas, United States*

The Shared Meaning Model (SMM) is a grounded theory, derived in a previous study. This model demonstrates pathways for communication between nurse and primary care providers (PCPs) in the nursing home (NH). In this study we used the SMM for feasibility testing of a clinical decision support app (CDS app) using a descriptive, structured observational design. This study also provided a forum for initial testing of the SMM. The CDS app algorithm provided a common language to assess a resident with the goal of sharing this information with a PCP. The CDS app guided licensed vocational nurses (LVNs) (N=10) in assessing a standardized nursing home resident in a simulation setting experiencing symptoms of a potential urinary tract infection (UTI). Interviews with LVNs provided details of CDS app usability and concerns about using the CDS app with NH residents. Videos recorded LVNs interacting with the resident while using the CDS app on an iPad®. Time-stamps logged duration of the assessment. Bookmarked segments were used for discussion in LVN interviews. Videos were coded for eye contact, conversation, and touch between LVN and resident and documented personalized interactions. Findings indicated areas (lab values, drug names) for changes to language in the algorithm. In less than 12 minutes the CDS app enabled LVNs to collect information based on language used by PCPs to make decisions about the presence of a UTI. Relationships between initial constructs in the SMM were supported. This CDS app holds promise for building a common language to enhance interprofessional communication.

THE IMPACT OF UNMET ADL NEED ON THE SELF-RATED HEALTH AND LIFE SATISFACTION OF CHINESE OLDER ADULTS

Jing Huang,¹ Edmond Pui Hang Choi,² and Pui Hing Chau,² 1. *School of Nursing, The University of Hong Kong*, 2. *The University of Hong Kong, Hong Kong, Hong Kong*

This study aims to examine the associations of change in unmet need for assistance with Activities of Daily Living (ADL) with the self-rated health and life satisfaction of community-dwelling Chinese older adults. Using national longitudinal data from the Chinese Longitudinal Healthy Longevity Study, we examined the associations of unmet ADL need with self-rated health and with life satisfaction from baseline (T1) to a 3-year follow-up (T2) among 1,914 older adults with ADL limitation. Change in unmet ADL need was categorized into “Persistently Unmet”, “Unmet at T1 Only”, “Unmet at T2 Only”, and “Never Unmet”. Self-rated health and life satisfaction were rated by 5-point Likert scales. Linear mixed models were performed to examine the associations, controlling for sociodemographic factors, health conditions, and social support. The results showed that older adults whose ADL needs were persistently unmet, those unmet at T2 only, and those never unmet, experienced a significant decline in self-rated health from baseline to

follow-up, but those unmet at T1 only experienced a significant rise in self-rated health. While the life satisfaction was stable from baseline to follow-up among older adults whose ADL needs were persistently unmet or never unmet, it significantly decreased among those unmet at T2 only and significantly increased among those unmet at T1 only. The effects of unmet ADL need on self-rated health and life satisfaction appeared to be short-term rather than long-term. These findings facilitate a better understanding of unmet ADL need and emphasize the importance to fully meet the ADL needs of older adults.

WHAT IS KNOWN ABOUT CYCLING WITHOUT AGE: A SCOPING LITERATURE REVIEW

Nicole Kaufman,¹ Aleksandra Zecevic,² Suna Christensen,³ and Cotnam Victoria,⁴ 1. *University of Western Ontario, Toronto, Ontario, Canada*, 2. *Western University, London, Ontario, Canada*, 3. *Independent Researcher, Copenhagen, Hovedstaden, Denmark*, 4. *Western University, Western University, Ontario, Canada*

The Cycling Without Age (CWA) program provides residents of long-term care homes with a bike ride experience, as a volunteer pedals them around the community in a specially designed trishaw. There is limited evidence of the program's effectiveness on older adults, pilots, and communities. The purpose of this literature review is to scope and summarize contemporary CWA discourses to generate future research questions that will provide evidence for future implementation of CWA. Data collection and analysis followed Arksey and O'Malley's 2005 framework. A systematic search was conducted in PubMed, OMNI, and Ebscohost databases. A grey literature search strategy incorporated: grey literature databases, customized Google searches, targeted websites, consultation with expert librarians, and a social media analysis on Twitter, Facebook and LinkedIn. Content analysis was used to identify the key themes. A total of 165 sources (2 peer-reviewed, 103 grey literature, 60 social media) were included in the final analysis. The three main themes were (a) meaning from being on a bike, (2) impacts of CWA, and (3) formation of relationships. Findings suggest that the CWA program brought valuable meaning to the participants' lives, significantly improved their happiness, and was associated with the formation of new and diverse intergenerational relationships. A large amount of anecdotal evidence, social media chatter, and global adoption of CWA indicate its importance and potential to satisfy the need of older adults to engage with society. Future research on the physical and mental health benefits of CWA is required to support further implementation of the program.

WOMEN WITH OBESITY ARE MORE LIKELY TO HAVE LONG-TERM INDWELLING BLADDER CATHETERIZATION IN U.S. NURSING HOMES

John Harris,¹ Mary Ackenbom,¹ Alison Trinkoff,² Steven Handler,¹ John Engberg,³ David Wolf,⁴ and Nicholas Castle,⁵ 1. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*, 2. *University of Maryland, Baltimore, Maryland, United States*, 3. *RAND, Pittsburgh, Pennsylvania, United States*, 4. *Bellarmine, Louisville, Kentucky, United States*, 5. *West Virginia University, Allison Park, Pennsylvania, United States*

Reducing indwelling catheters and increasing clean intermittent catheterization is a key element of effective infection control and maintaining functional independence in nursing homes. Nursing care is often more difficult as obesity increases, leading to more nursing care or equipment to provide care. We hypothesized that nursing homes are more likely to use indwelling catheters for people with obesity because indwelling catheterization likely eases the nursing burden of toileting and personal hygiene care for residents with obesity. The study design was a retrospective cohort study of U.S. nursing home female residents in Minimum Data Set in 2013. Obesity and normal weight (the reference group) were categorized using National Institutes of Health criteria. Indwelling and intermittent bladder catheterization was defined during periodic assessment of residents. We modeled the outcomes using logistic regression using a robust variance estimator. Model covariates included obesity category, resident age, dementia status, comatose status, Stage 3 or 4 pressure ulcers, and the number of activities of daily living deficits. The study cohort included 1,068,388 female residents in 15,230 nursing homes. Obesity (BMI ≥ 30 kg/m²) prevalence was 31.9%. The prevalence of indwelling catheterization was 5.2% and of intermittent catheterization was 0.4%. The odds ratio of indwelling catheter use for obese residents varied from 1.05 to 1.74 (all with p-values <0.001), whereas the odds ratio of intermittent catheter use varied from 0.84 to 0.46 (all with p-values <0.01) compared to residents of normal weight. Increasing obesity is independently associated with increased long-term indwelling bladder catheterization and decreased intermittent catheterization.

Older Adults' Experiences and Perceptions of the COVID-19 Pandemic

Session 9400 (Poster)

"IT IS THE SCOURGE OF GOD" MISCONCEPTIONS OF COVID 19 PANDEMIC AMONG OLDER MARKET TRADERS IN IBADAN, NIGERIA

Olubukola Omobowale,¹ and Adeola Fowotade,² 1. *University of Ibadan, Nigeria, Ibadan, Oyo, Nigeria*, 2. *College of Medicine, Ibadan, Oyo, Nigeria*

Abstract Background: Community perception on COVID-19 can influence the development of the right attitude towards mitigating the spread of the Sars CoV 2 virus. Older adults are at risk of severe infections and mortality is high among them. **Objectives:** This study was conducted to document the knowledge, perceptions and misconceptions of COVID-19 among older market traders in Ibadan, Oyo State, Nigeria. **Methods:** A cross-sectional study conducted in two densely populated markets in Ibadan. An interviewer-administered semi-structured questionnaire was used to collect data on the knowledge and perception of COVID-19. Data were analyzed using SPSS version 23. Level of significance was set at $p < 0.05$. **Results:** A total of 321 respondents were sampled. All participants were aware, source was mainly through radio (93.5%), and 65.8% believed COVID-19 was as a scourge from God for punishments of sins. Only 41.1% had good knowledge of spread with personal contact (95.3%) mostly reported. On knowledge of symptoms and

preventive measures, dry cough (84.7%) and frequent hand washing (95.6%) were mostly reported. Knowledge of cause was significantly associated with age ($p=0.04$) and marital status ($p=0.001$), while level of education ($p=0.012$) was significantly associated with knowledge of spread. Conclusion: Misconceptions about the knowledge of the cause and spread of COVID-19 were prevalent among the study population. The implication of this finding among older adults and the significant effect of some sociodemographic factors on the knowledge of the cause and spread of COVID-19 calls for urgent health-promoting interventions that would dispel the misconceptions.

AGE AND GENDER DEMOGRAPHICS PREDICT COMPLIANCE WITH COVID-19 PUBLIC HEALTH MEASURES: DATA FROM A GLOBAL SAMPLE

Amber Heemskerk,¹ Tian Lin,¹ Elizabeth Harris,² Jay Van Bavel,³ and Natalie Ebner,¹ 1. *University of Florida, Gainesville, Florida, United States*, 2. *New York University, New York City, New York, United States*, 3. *New York University, New York, New York, United States*

The COVID-19 global pandemic has brought far-reaching consequences on individual and societal levels. Social distancing and physical hygiene constitute effective public health measures to limit the spread of the virus. The current study investigates individual age and gender demographics, in interaction with a country's human development index (HDI), as crucial factors influencing compliance with public health measures in a large multi-national adult lifespan sample. This report leverages data from a large-scale international collaboration (Van Bavel et al., 2020; <https://psyarxiv.com/ydt95/>) comprising 45,576 individuals from 66 countries/territories. Participants provided self-reports of their compliance/agreement with three public health measures (i.e., spatial distancing, physical hygiene, policy support). Older age, female gender, and lower HDI were independently associated with greater compliance with public health measures. In addition, a significant three-way interaction between participant age, participant gender, and a country's HDI revealed that compliance was lowest in younger adults from well-developed countries, while compliance was highest among females across all ages from less-developed countries. Compliance with public health measures is crucial in effectively reducing coronavirus spread. Our findings suggest that age and gender as individual-level demographics, in tandem with HDI as a country-level predictor, affect individuals' willingness to comply with public health measures. These results highlight the potential of data-driven, tailored (i.e., towards specific demographics) health campaigns and public policies in the fight against a global pandemic.

AGE DIFFERENCES IN POSITIVE EVENT APPRAISALS DURING COVID-19: EVIDENCE FROM A DAILY DIARY STUDY

Patrick Klaiber, Lydia Ong, Anita DeLongis, and Nancy Sin, *University of British Columbia, Vancouver, British Columbia, Canada*

Multiple studies suggest that community-dwelling older adults are psychologically resilient in the face of the COVID-19 pandemic. Notably, during the initial weeks of the COVID-19 outbreak, older age was associated with engaging

in more daily positive events (Klaiber et al., 2021, *Journal of Gerontology: Psychological Sciences*). We followed up on these findings by exploring age differences in positive event appraisals during the COVID-19 pandemic. During the 7-day diary study conducted between March and August 2020, 1036 participants (mean age = 45.95, SD = 16.04, range = 18-91) reported their positive events in nightly surveys. If at least one positive event occurred, participants rated their appraisals of the event on the following dimensions: importance, calmness, happiness, gratitude, personal responsibility, and control. Older adults (60 years+) rated their positive events to be more personally important and felt more calm and happy during these events, compared to younger (18-39 years) and middle-aged adults (40-59 years). Furthermore, older adults felt more grateful during positive events compared to younger but not middle-aged adults. There were no age differences in feelings of control or personal responsibility for positive events. These findings highlight the importance of daily positive events for older adults during a time of major stress. In line with theories on adult development, daily positive event processes in older adults are characterized by valuing positive and meaningful social connections, as well as a greater degree of positive event-specific emotions such as feeling calm, happy, and grateful.

ATTITUDES AND BELIEFS OF OLDER BLACK AMERICANS TOWARD THE COVID-19 VIRUS AND VACCINE

Dwana Bass,¹ Sophie Hanna,² Sarah Shair,³ Loraine DiCerbo,² Bruno Giordani,⁴ and Voyko Kavcic,² 1. *Institute of Gerontology - Wayne State University, Sterling Heights, Michigan, United States*, 2. *Wayne State University, Detroit, Michigan, United States*, 3. *University of Michigan, University of Michigan, Michigan, United States*, 4. *Neuropsychology/Michigan Alzheimer's Disease Research Center, University of Michigan, Ann Arbor, Michigan, United States*

The COVID-19 pandemic, an unprecedented health emergency, has devastated the nation, and disproportionately affected persons of color, especially Black Americans. It has forced health officials to rapidly develop and distribute COVID-19 vaccines, resulting in the importance of understanding Black Americans' attitudes and beliefs about COVID-19. We analyzed experiences of 167 Black Americans, ages 65 and older, recruited from Wayne State Institute of Gerontology Healthier Black Elders Center and surrounding communities. Participants were telephoned starting September 2020 and given the GAD-7 anxiety scale and a COVID-19 questionnaire measuring demographics, stressors, and emotional responses associated with the COVID-19 pandemic. A scale was also designed, adapted from the Health Belief Model, to measure fear of getting COVID-19, beliefs about the origins of COVID-19, uncertainty about vaccine safety, and intent to be vaccinated (5-point Likert scale). Of the 167 participants, 112 (67%) said they would agree to vaccination, 24 (14%) were ambivalent, and 31 (19%) said they would decline. T-tests comparing pro- and anti-vaccine participants showed that those not planning to get vaccinated expressed lower generalized anxiety ($p=.002$), COVID-19 fear ($p<.001$), and concerns about vaccine safety ($p=.01$), but greater belief that COVID-19 is man-made ($p=.05$). The

current study provides a snapshot of urban Black American older adults who are in general eager to get vaccinated for COVID-19. Counterintuitively, those unwilling to accept the COVID-19 vaccine also had lower concerns for vaccine safety. More research is needed to fully understand the attitudes and beliefs of this underserved population regarding the COVID-19 virus and vaccine.

EXPLORING OLDER ADULTS' LIVED EXPERIENCES OF COVID-19: A NARRATIVE INQUIRY STUDY

Tia Rogers-Jarrell,¹ and Brad Meisner,² 1. *York University, Hamilton, Ontario, Canada*, 2. *York University, Toronto, Ontario, Canada*

COVID-19 dramatically changed daily life for older adults in numerous and complex ways. Research is calling for an understanding on how COVID-19 has and will impact aging, and older adults' lived experiences with aging, within the context of the pandemic. Social and physical distancing guidelines have put older adults at an increased risk for social isolation. Intergenerational tensions have also intensified during the pandemic, and early research states the labeling of older adults as a homogenous and "vulnerable" group can lead to an increased risk of ageism in their communities. Therefore, the purpose of this study is to explore how community-dwelling older adults (ages 65 and greater) experience daily life amid the COVID-19 pandemic using a biopsychosocial approach. This study employs a critical qualitative narrative inquiry design. Data will be collected through solicited diaries and semi-structured individual interviews (via telephone and video conferencing software). Data will be analyzed thematically and involve a re-storying of the findings. Preliminary results will be presented and discussed. This study aims to inform new and critical perspectives that broaden our understanding of how the overall health, wellness, and quality of life of older adults can be supported. Findings contribute to the current and developing knowledge of older adults' first-person accounts of their experiences within the COVID-19 pandemic.

FACTORS PREDICTING COMMUNITY-DWELLING OLDER ADULTS' COVID-19 EXPERIENCES IN CENTRAL TEXAS

Atami De Main,¹ Bo Xie,² Kristina Shiroma,³ and Nathan Davis,² 1. *The University of Texas at Austin, Menard, Texas, United States*, 2. *The University of Texas at Austin, Austin, Texas, United States*, 3. *The University of Texas at Austin, The University of Texas at Austin, Texas, United States*

Older adults, disproportionately affected by the COVID-19 pandemic, face health, social and structural vulnerabilities. Their experiences require systematic examination. Our study aimed to examine factors predicting community-dwelling older adults' experiences during COVID-19. We collected data via the telephone between June-August 2020 from a convenience sample of older adults in Central Texas (N= 200; age range=65-92 years; Mean=73.6, SD=6.33). We conducted multinomial logistic regression analyses to model relationships between self-reported COVID-19 experiences (positive, mixed, negative) and age, gender, race, income, education, frequency of communication with family and friends, feelings of loneliness and amount of COVID-19

information obtained. Factorial analysis revealed no statistically significant interaction effect. Multinomial logistic regression analysis revealed statistically significant main effects of annual household income, feelings of loneliness and amount of COVID-19 information obtained on predicting COVID-19 experiences. Age, gender, race, education, and frequency of communication with family and friends were not significant predictors. The odds of having a positive COVID-19 experience rather than negative experiences increased by 6.94 for an annual household of \$60,000- \$99,999, and by 6.02 for not feeling lonely. The odds of having a positive experience during COVID-19 rather than mixed increased by 9.90 for an annual household income of \$100,000 or more. Participants who reported having "too much information" about COVID-19 were more likely to have mixed experiences compared to those with positive experiences. Our findings underscore the crucial role of financial security and social connections in reducing economic and emotional challenges older adults are facing during this crisis.

FRAMING THE COVID-19 PANDEMIC THROUGH A FAMILY LENS: RESULTS OF A QUALITATIVE THEMATIC ANALYSIS

Lauren Gilbert,¹ Omolola Adepoju,² LeChauncy woodard,² and Daniel Howard,³ 1. *University of Houston College of Medicine, Houston, Texas, United States*, 2. *Humana Integrated Health System Sciences Institute, Houston, Texas, United States*, 3. *Texas A&M University at College Station, Texas A&M University at College Station, Texas, United States*

Background: The growing proportion of older adults in the U.S. population tends to be most vulnerable to the effects of natural disasters such as pandemics. To date, little has been done to counteract the impacts of public health emergencies and disasters on the aging populations, particularly in African American and Latinx communities. Methods: We administered a survey to community-dwelling minority older adults, 55+, in the Houston metroplex, between 11/2020 and 01/2021. The survey assessed how the COVID-19 pandemic has impacted minority older adults. This thematic analysis focused on open-ended questions regarding daily health management, biggest health concerns, and personal experiences with COVID-19. Results: A total of 575 older adults completed the survey. The mean age was 69 years, 74% were female, 71% reported English as their primary language and 27% were college educated. Three main themes of COVID-19 related concerns emerged from the thematic data analysis: 1) Fear of contracting COVID-19 from family members and fear of passing COVID-19 on to family members. 2) Social needs, including prolonged isolation from family/friends to stay safe, obtaining basic necessities such as food, medications, and transportation. (3) Personal experiences focused on COVID-19 cases, hospitalizations, and deaths of family/community members. Conclusions: These older minority adults framed their experiences and concerns regarding the COVID-19 pandemic through the lens of family and their community. Their personal relationships permeated their responses and demonstrate the importance of integrating a family lens into future disaster planning, response and recovery efforts for minority older adults.

LISTENING TO OLDER ADULTS: A QUALITATIVE ANALYSIS OF ADVICE GIVEN DURING COVID-19

Bryce Van Vleet,¹ Heather Fuller,² and Andrea Huseth-Zosel,¹ 1. *North Dakota State University, Fargo, North Dakota, United States*, 2. *North Dakota State University, Fargo, North Dakota, United States*

The life experience of older adults offers a unique perspective of coping through historical crises. Specific advice offered by older adults is generally underrepresented in the literature. This qualitative study explores advice offered by older adults to others on how to cope through the COVID-19 pandemic as well as advice for the community about the needs of older adults. A Midwestern sample of 67 older adults aged 70-97 completed one phone interview in June of 2020 as part of a larger study about their experiences with social distancing and isolation. Participants were asked what advice they would give to others during the pandemic and what advice they would give to communities and families about the needs of older adults during the pandemic. Transcripts of these conversations were coded using in vivo and holistic coding as first-cycle methods. These codes were then analyzed using pattern coding as a second-cycle method. Results indicated older adults offered advice along three domains: fostering physical and mental wellbeing, promoting positive life perspectives, and maintaining connections. Advice to communities regarding the needs of older adults included having a selfless attitude and taking intentional actions like grocery shopping and writing letters. However, older adults also recommended avoiding extremes to allow them to maintain their independence and preserve physical distance for safety. Older adults utilized their life perspective and their own coping strategies when offering advice. Future research should evaluate the effectiveness of the advice given and how likely that the advice will be utilized by others.

NATIVE AMERICAN ELDERS' EXPERIENCES DURING THE COVID-19 PANDEMIC: CASE STUDIES

Bo Xie,¹ Kristina Shiroma,² John Lowe,¹ Atami De Main,³ and Nathan Davis,¹ 1. *The University of Texas at Austin, Austin, Texas, United States*, 2. *The University of Texas at Austin, The University of Texas at Austin, Texas, United States*, 3. *The University of Texas at Austin, Menard, Texas, United States*

The COVID-19 pandemic has affected community-dwelling elder adults' experiences during the COVID-19 pandemic. We report 4 case studies of Native American elders' pandemic experience. Participants were recruited from community-dwelling older adults in Central Texas. Data collection took place via in-depth, semi-structured telephone interviews during June-August 2020. Four of the participants self-identified as Native American. Three of them were male; between the ages of 74 and 75; had at least some college education. The fourth Native American elder was a 68 year-old female with some college education. All four participants were coping well with everyday life during the pandemic. Connectedness emerged as the overarching theme among the

4 cases. Regular communication with their families was expressed as most important. A variety of communication technology was used to maintain contact with family members such as phone calls, texting, email, and video chat services particularly Zoom, FaceTime, and Facebook Video Chat. Challenges with using these technologies were also frequently reported. The participants expressed they did not feel a sense of increased loneliness or loss of being connected. Another theme emerged related to surviving the impact of the pandemic. Having the vaccine accessible along with financial resources necessary to sustain essential needs were most frequently expressed by the participants. These findings have implications for community interventions and policies that support the provision of mechanisms for Native American elders to maintain a sense of connectedness, including the adoption and use of communication technology, during times of crises such as pandemics and natural disasters.

PERCEIVED FEAR OF COVID-19 AMONG NEPALI OLDER ADULTS

Saruna Ghimire,¹ Uday Narayan Yadav,² Om Prakash Yadav,³ and Janardan Subedi,⁴ 1. *Miami University, Oxford, Ohio, United States*, 2. *University of New South Wales, SYDNEY, New South Wales, Australia*, 3. *Ministry of Health and Population, Kathmandu, Bagmati, Nepal*, 4. *Miami University, Miami University, Ohio, United States*

Although coronavirus-disease-2019 (COVID-19) impacted everyone in some ways, it disproportionately impacted the older population. Given their increased vulnerability to severe illness and mortality, the ongoing pandemic has created greater distress, anxiety, and fear among the older population. In Nepal, a South Asian country nestled in the Himalayas between India and China, most stories of older adults are untold—both in the pre-COVID-19 and the COVID-19 era. This study aimed to explore the perceived fear of COVID-19 among Nepali older adults. A cross-sectional study was conducted between July-September 2020 among 847 older adults (≥60 years) residing in three districts of eastern Nepal. The seven-item Fear of COVID-19 Scale assessed the perceived fear of COVID-19; higher scores on the scale (ranges 7 to 35 indicated greater fear. A sizeable proportion of the participants' reported being afraid (35%), anxious (32%), uncomfortable (24%), clammy (14%), and sleepless (12%), while 28% were fearful of losing their life due to COVID-19. In adjusted regression analysis, older age group, Dalit (minority) ethnicity, and remoteness to the health facility were associated with greater fear of COVID-19. Surprisingly, pre-existing health conditions were inversely associated with fear of COVID-19. Greater fear of COVID-19 amidst the pandemic, although anticipated, urges us to reflect on the most vulnerable groups' psychological needs not just during COVID-19 but in the future events of pandemics and public health emergencies. Fear during emergencies could be battled with accurate and effective information as well as better preparedness and psychosocial interventions.

Session 9405 (Poster)

Pain Assessment, Management, and Palliative Care

INTER- AND INTRA-RACIAL DIFFERENCES IN PAIN AND PERFORMANCE-BASED FUNCTION IN OLDER ADULTS WITH OSTEOARTHRITIS

Staja Booker,¹ and Roger Fillingim,² 1. *University of Florida, GAINESVILLE, Florida, United States*, 2. *University of Florida, Gainesville, Florida, United States*

Osteoarthritis (OA) contributes to movement-evoked pain, impaired function and mobility, and reduced quality of life among older adults. Assessment of pain has not traditionally considered the dynamic changes that occur with gross motor movement, and thus self-reports of pain often reflect static or resting pain. This case-control pilot study examined inter- and intra-racial differences in movement-evoked pain and performance-based function in older adults (N= 28) with knee OA. Cases consisted of Blacks and Whites with OA; controls included Blacks without OA. The Biodex Pro System 4, an isokinetic and isometric dynamometer commonly used in rehabilitative medicine, measured knee muscle function. Pain intensity was assessed pre-, ante-, and post- completion of 2 repetition sets of five alternating knee flexion and extension maximum voluntary contractions at angular velocities of 90° (greater resistance) and 180° (lower resistance). Repeated Measures Analysis of Variance with Bonferroni correction identified statistically significant differences in pain for within- and between-subjects at 90° and 180°. Pain increased during the repetitions and decreased after completion of both repetition sets; this non-linear relationship was significant (p= .004). One-way ANOVA demonstrated peak torque (extension), a muscle's maximum strength capability, was significantly higher in White cases and Blacks controls compared to Blacks cases. Novel findings revealed that baseline pain is much higher and functional performance is significantly lower in Blacks with OA compared to White cases and Black controls. This research advances precision pain measurement and our understanding of the biological mechanisms uniquely involved in the experience of knee OA and mobility.

MEDICAL COMPLEXITY, MORTALITY AMONG HIGH-COST MEDICARE ADVANTAGE ENROLLEES: PALLIATIVE, HOSPICE IMPLICATIONS

Samuel Amodeo,¹ Henrik Kowalkowski,² Lauren Bangerter,³ Halley Brantley,⁴ David Cook,⁵ and Nicholas Jones,⁶ 1. *OptumLabs at UnitedHealth Group, Inver Grove Heights, Minnesota, United States*, 2. *UnitedHealth Group, Minneapolis, Minnesota, United States*, 3. *OptumLabs, Eden Prairie, Minnesota, United States*, 4. *UHG, Minnetonka, Minnesota, United States*, 5. *United Health Group, Optum Labs, Minnesota, United States*, 6. *Brown University School of Public Health, Brown University, Rhode Island, United States*

Older adults with high medical spend require tailored interventions and care delivery to meet their complex needs. Palliative is a high-value solution for high-cost patients

because it provides relief from the symptoms, pain, and stress associated with multiple conditions. Likewise, other high-cost patients may be closer to end-of-life and therefore benefit from hospice care. For Accountable Care Organizations (ACOs) and hospitals to implement palliative care, these programs must identify and target the high-need patient populations. This study explored patterns of spending and mortality across 4 years (2016-2019) using claims from 1,701,647 patients continuously enrolled in UnitedHealth Group Medicare Advantage (mean age=73.7; S.E.=0.01). Patients with healthcare spend in the top decile were segmented into three subgroups based on health conditions and spend patterns. Analyses identified a subgroup of patients (mean age=76.6; S.E.=0.04), with the highest rate of mortality, and significantly more chronic conditions and frailty, indicating their cost and mortality was driven by medical complexity. Odds ratios from a multinomial logistic model tie blood formulation drugs (OR XX), medicative procedures (OR XX), and nonhospital-based care (OR XX) to members of this subgroup may be connected to short-term mortality. There is a critical need to identify patients who stand to benefit from palliative and end of life care, this is particularly true for high-cost high-need patients. Our study suggests that patterns of medical complexity and mortality within high-cost patient subpopulations can be used to identify high-cost patients who would benefit from palliative or hospice care.

MISSED OPPORTUNITIES FOR COMPASSION: A CALL TO ACTION FOR INCARCERATED INDIVIDUALS DENIED COMPASSIONATE RELEASE

Claire Morton,¹ Rachel Nathan,² Anjana Chacko,³ and Raya Kheirbek,⁴ 1. *Une, Baltimore, Maryland, United States*, 2. *University of Maryland School of Medicine, University of Maryland, Maryland, United States*, 3. *University of Maryland, Baltimore, Maryland, United States*, 4. *University of Maryland School of Medicine, University of Maryland School of Medicine, Maryland, United States*

In 2016, a total of 4,117 state and federal prisoners died in publicly or privately operated prisons. Each year from 2001 to 2016, an average of 88% of deaths in state prisons were due to natural causes, with more than half of those due to cancer, heart disease or liver disease, conditions for which non-incarcerated citizens often benefit from palliative care and hospice. Prisoners age 55 and older are the fastest-growing segment of the population residing in prisons, as well as those with the highest mortality rate. Compassionate release of seriously ill prisoners became a matter of federal statute in 1984 and has currently been adopted by the majority of U.S. prison jurisdictions. The spirit of the mandate is based on the idea that catastrophic health conditions ie terminal illness affect the four principles of incarceration: retribution, rehabilitation, deterrence, and incapacitation. Concerned about an aging prison population, overcrowded facilities, and soaring costs, many policy makers are calling for a wider use of compassionate release for persons with terminal illness as well as broader prison reform. The prognosticating criteria of compassionate release guidelines are clinically flawed, and the application and procedural barriers

are prohibitive. In this paper we review cases of patients who qualified for compassionate release but had their applications denied. We will discuss the urgent need for access to quality palliative medicine for incarcerated persons with advanced illness and call healthcare providers to action with the aim of reducing suffering and promoting social justice for those in need.

PREVALENCE OF MUSCULOSKELETAL PAIN AND ANALGESIC TREATMENT AMONG HOME-DWELLING OLDER ADULTS: CHANGES 1999–2019

Tuuli Lehti, and Kaisu Pitkälä, *University of Helsinki, Helsinki, Uusimaa, Finland*

Pain has been shown to be undertreated in the older population. At the same time, the increased opioid use is of concern in the Western world. This study analyzes temporal trends in pain management among home-dwelling people aged 75 to 95 using cross-sectional cohort data spanning 20 years. The Helsinki Aging Study recruited random samples aged 75, 80, 85, 90, and 95 in 1999, 2009, and 2019. In total, 5,707 community-dwelling people participated in the questionnaire survey. Participants reported their medical diagnoses, regular prescription medications, and the presence of back pain or joint pain within the last 2 weeks (never, sometimes, or daily). We compared analgesics use in people reporting musculoskeletal pain and in people not reporting pain in 1999, 2009, and 2019. Of participants, 57–61% reported intermittent or daily musculoskeletal pain. The percentage of people taking a daily analgesic increased from 9% in 1999 to 16% in 2019. The use of NSAIDs decreased from 1999 to 2019, while the use of paracetamol increased from 2% to 11%. Of participants, 3% took daily opioids in 2019. Of those reporting daily musculoskeletal pain, 20% in 1999, 35% in 2009 and 32% in 2019 took regular pain medication. Pain remains undertreated in the older population, although the use of regular prescribed analgesics increased from 1999. The use of NSAIDs diminished, while the use of paracetamol increased. Daily opioid use remained modest from 1999 to 2019.

QUALITATIVE DOCUMENT ANALYSIS OF PATIENT'S HEALTHCARE TRAJECTORY WITH AND WITHOUT PALLIATIVE CARE

Melissa Steffen,¹ Kenda Stewart Steffensmeier,² Bruce Alexander,³ and Maresi Berry-Stoelzle,³ 1. *VA Office of Rural Health, Veterans Rural Health Resource Center-Iowa City (VRHRC-IC), Iowa City, Iowa, United States*, 2. *Iowa City VA Health Care System, Iowa City, Iowa, United States*, 3. *Iowa City VA Medical Center, Iowa City, Iowa, United States*

Palliative care is important to the care of seriously ill patients to support the patient and family. Palliative care is often timely in the inpatient setting, but delayed in outpatient care, leading to missed opportunities. Identifying when to engage patients with palliative care in outpatient settings has been challenging. As part of a larger quality improvement project to increase access to palliative care, a qualitative sub-study was completed to identify missed palliative care engagement opportunities in patient's healthcare trajectories. A document analysis of patients notes from a convenience sample of 20 recently deceased patients who received care within

the Veteran Affairs healthcare system (VAHCS) was completed. Patients were sorted into four categories that emerged from initial analysis: cancer/palliative, non-cancer/palliative, cancer/non-palliative, and non-cancer/non-palliative. Two qualitative analysts reviewed the notes, paying particular attention to notes preceding or following seminal healthcare events. Patients in the cancer/non-palliative category were more likely to decline preventive care, engage less with the VAHCS health care or only interacted with the VAHCS for specific needs (e.g., determine VA health benefits). Similarly, non-cancer/non-palliative care patients were more likely to use a mix of VAHCS and outside healthcare, with inpatient care occurring outside of the VAHCS. For non-palliative care patients, seminal healthcare events were less likely to occur in the VAHCS. Thus, identifying opportunities to engage patients with palliative outside of seminal healthcare events may be important to increasing patient access within the VAHCS.

RELIABILITIES OF MEAN AND VARIABILITY OF AMBULATORY PAIN AMONG COMMUNITY DWELLING OLDER ADULTS

Jinshil Hyun, Jiyue Qin, Cuiling Wang, Mindy Katz, Jelena Pavlovic, Carol Derby, and Richard Lipton, *Albert Einstein College of Medicine, Bronx, New York, United States*

Individual's pain experiences vary substantially over time periods, and the variability in pain may be an important metric to predict health consequences. However, research on its reliability is lacking among older adults. We aimed to examine the reliabilities of both intra-individual mean (IIM) and intra-individual variability (IIV) of subjective pain reports assessed using ecological momentary assessments (EMA) among racially diverse, community dwelling older adults. Participants were from the Einstein Aging Study (N=311, age=70-91) and completed a 14-day EMA protocol which included self-reports of pain intensity 6 times a day. Pain IIV was quantified using intraindividual standard deviation (iSD). We followed Wang and Grimm(2012)'s approach to calculate the reliability of IIM and IIV. Over a 2-week period, we found excellent reliabilities for both pain IIM (.99) and pain IIV (.91), showing that these measures are reliable and can be used to link with various health outcomes among community dwelling older adults. We also estimated the average number of assessments that produce acceptable levels of reliability. The average of 2 assessments for pain IIM and 23 assessments for pain IIV produced values that exceeded reliability score of .80, suggesting that a briefer study design may be used to reduce participants' burden with reliable pain metrics. Future studies need to examine whether pain IIV is associated with cognitive, emotional, and physical health among older adults and whether intervention studies that target to reduce pain IIV improve health consequences.

SUPPORTING INNOVATIVE STRATEGIES TO REDUCE OPIOID-RELATED HARMS AMONG OLDER ADULTS IN PRIMARY CARE

Rosanna Bertrand,¹ Nicole Keane,² Sarah Shoemaker-Hunt,² Clarissa Hsu,³ Michael Parchman,³ Sebastian Tong,⁴ and Arlene Bierman,⁴ 1. *Abt Associates, Abt Associates, Massachusetts, United States*, 2. *Abt*

Associates, Cambridge, Massachusetts, United States, 3. Kaiser Permanente of Washington Health Research Institute, Seattle, Washington, United States, 4. Center for Evidence and Practice Improvement (CEPI), Agency for Healthcare Research and Quality (AHRQ), Rockville, Maryland, United States

Older adults are more likely to be prescribed opioids and to suffer from opioid-related harms. Despite growing concerns about opioid misuse in older adults, providers and health care systems often struggle with approaches that would effectively manage opioid use and reduce opioid misuse in older adults. To address this issue, the Agency for Healthcare Research and Quality funded a four-year project to work with primary care practices in developing and testing innovative strategies for opioid management in older adults. To develop a change package that will inform learning collaboratives where primary care practices will be encouraged to test new or modified strategies in managing opioids in older adults, Abt, the contractor, first completed an environmental scan to identify existing resources/tools. Identified resources/tools were vetted by an expert panel and appropriate items were used to develop a change package consisting of nine high-leverage change (HLC) strategies (e.g., Develop processes/workflows that clearly define roles/responsibilities and promote coordinated team-based care). In the change package, multiple key activities that accompany each HLC strategy are presented as examples of strategies that could be implemented to bring about the selected HLC. Primary care practices participating in learning collaboratives will use the change package to guide the development and testing of strategies to manage opioids in their older adults, which will inform the development and refining of a compendium of strategies to best reduce harms of opioid use in older adults.

Session 9410 (Poster)

Pain, Pain Management, and Palliative Care

AGE DIFFERENCES IN THE USE/EFFICACY OF EMOTION COPING STRATEGIES AMONG ADULTS WITH CHRONIC PAIN: A SCOPING REVIEW

Gillian Fennell,¹ Elaine Wethington,² M. Carrington Reid,³ Erica Sluys,¹ Kelsey Donovan,⁴ Valeria Cardenas,¹ Elizabeth Zelinski,¹ and Susan Enguidanos,¹ 1. *University of Southern California, Los Angeles, California, United States, 2. Cornell University, Ithaca, New York, United States, 3. Weill Cornell Medical College, New York, New York, United States, 4. University of Massachusetts Amherst, Amherst, Massachusetts, United States*

Active coping strategies (e.g., exercise and pharmacological treatments) typically do not leave chronic pain patients completely pain-free. Therefore, individuals turn to emotion-focused strategies to cope with associated impairment and psychosocial consequences. General coping strategy use has been shown to differ by age. This scoping review explored age differences in the use and effectiveness of emotion-focused strategies in adults experiencing chronic pain. Studies were located via advanced searches in PubMed, PsycINFO, CINAHL, Embase, Web of Science, and Proquest Dissertations and Theses Global and referral. Two reviewers independently conducted abstract screenings and full-text extractions. Conflicts

were discussed and resolved by the PI. We identified 15 studies that met our inclusion criteria, of which 14 met criteria for high methodologic quality. The majority of studies utilized the Coping Strategies Questionnaire to assess differential use of pain-coping strategies. The remaining studies used one of five other questionnaires. Only one study examined the differential effect of age on the efficacy of emotion-focused strategies. Five of the eight studies that examined hoping/prayer coping reported the strategy's positive association with age. Age was not associated with ignoring pain or reinterpreting pain sensations in any of the eight studies in which these strategies were measured. We concluded that older age was associated with the use of praying/hoping as a means of coping with pain. No other consistent associations between age and other measured coping strategies were identified. Future research should account for auxiliary stressors and pain characteristics while investigating the differential effect of age on pain coping efficacy.

ASSOCIATIONS OF PAIN SEVERITY AND MOBILITY WITH AGE IN CHRONIC LOW BACK PAIN: DOES THE TYPE OF ASSESSMENT MATTER?

Taylor Buchanan, Deanna Rumble, Kristen Allen-Watts, Katie O'Neal, Tammie Quinn, Thomas Buford, and Burel Goodin, *University of Alabama at Birmingham, Birmingham, Alabama, United States*

Chronic low back pain (cLBP) can lead to severe pain symptoms as well as disability in adults. As individuals age, pain symptoms and mobility outcomes can become increasingly debilitating. However, current findings regarding the influence of age on symptoms and outcomes are mixed and may be attributed to the assessment methodologies for pain and mobility. Therefore, we sought to examine the association of age with broad and specific assessments of pain severity and mobility commonly implemented in adults with cLBP. cLBP participants (n = 158) completed questionnaires regarding pain intensity and disability including demographics, Clinical Pain Assessment (CPA) and the Oswestry Low Back Pain questionnaire (OLBP). Participants also completed assessments of movement-evoked pain and difficulty by performing the Short Physical Performance Battery (SPPB). Pearson's chi-square tests and regression-based analyses were conducted using SPSS version 26.0. Among cLBP participants, age was associated with pain-related disability indexed by section one of the OLBP regarding pain intensity (F= 5.0, p<.05), and mobility via total SPPB score (F= 11.7, p<.05). Interestingly, age predicted greater self-reported difficulty climbing stairs (F= 21.7, p<.05), performing chores (F= 17.0, p<.05), walking (F= 14.0, p<.05), and running errands (F= 13.4, p<.05) from the CPA. Further, age predicted total balance (F= 3.2, p<.05), gait speed (F= 7.8, p<.05), and chair stand (F= 6.5, p<.05) scores of SPPB. Age is associated with questionnaires assessing cLBP pain severity and is also associated with mobility outcomes. Future research should seek to understand the influence of age on movement-evoked pain in cLBP.

CHALLENGES WITH PAIN TREATMENT FOR RURAL OLDER ADULTS: FAMILY CAREGIVERS' VIEWS

Hyunjin Noh,¹ Cho Rong Won,² and Zainab Suntai,¹ 1. *University of Alabama, Tuscaloosa, Alabama, United States, 2. University of Alabama, Tuscaloosa, Alabama, United States*

Family caregivers face various challenges in assisting older adults experiencing pain and difficult symptoms. Living in rural areas poses additional obstacles to their caregiving. The purpose of this study was to explore family caregivers' lived experiences in caring for older adults with pain and discomfort in rural communities. A qualitative research design was adopted to capture the common essence of participants' experiences through a phenomenological method. Purposeful sampling was used, and the participant criteria was: age 18+, have good thinking skills, resident of Alabama, provide unpaid assistance to a family/relative who has chronic/serious health conditions and experienced pain/discomfort in the last 3 months. Ten participants were recruited from rural counties of Alabama. Individual semi-structured interviews were conducted via phone and were recorded and transcribed verbatim. Inductive, thematic analysis of the data revealed themes in five categories: 1) impact of pain (physical and psychological/emotional toll), 2) coping strategies (faith/contentment with life/logistical adaptation), 3) impact of Covid-19 (physical health/social interaction/mental health/added caregiving), 4) challenges in pain treatment (transportation (time/distance/driver/cost) and non-transportation related problems (healthcare provider issues/health insurance/financial burden)), and 5) suggestions (transportation-related (more transportation options/tailored services) and non-transportation-related support (home-based services/better health insurance coverage)). Findings of this study highlight rural family caregivers' unique experiences in assisting older adults' access to pain treatment, particularly during the Covid-19 pandemic. Policy- and program-level intervention is called for to increase individualized transportation options, improve health insurance coverage, and expand financial support for rural older adults experiencing pain and their caregivers.

CONNECTING THE DOTS: PAIN MENTAL MODELS OF SPOUSAL CAREGIVERS OF VETERANS WITH DEMENTIA AND PAIN

Phoebe Block,¹ Srijana Shrestha,² Tracy Evans,³ Michelle Hilgeman,⁴ Julia Loup,⁵ Mark Kunik,³ and A. Lynn Snow,⁵ 1. *Battle Creek VA Medical Center, Battle Creek, Michigan, United States*, 2. *Wheaton College Massachusetts, Norton, Massachusetts, United States*, 3. *Baylor College of Medicine, Houston, Texas, United States*, 4. *Tuscaloosa VA Medical Center, Tuscaloosa, Alabama, United States*, 5. *University of Alabama, Tuscaloosa, Alabama, United States*

Pain is prevalent among persons with dementia (PWDs), yet often goes underrecognized and undertreated. Exploring caregivers' pain mental models may provide valuable insight into how they conceptualize pain, and how such conceptualizations affect their identification of and response to PWDs' pain. We identified and described the pain mental model(s) of spousal caregivers of community-dwelling veterans with dementia and pain through a secondary qualitative thematic analysis of recordings of a psychosocial intervention aimed at preventing aggression in PWDs with pain. Thirty female spousal caregivers (11 Black, 10 non-Hispanic White, and 9 Hispanic) comprised the present sample. Two themes were identified: Pain Assessment Beliefs and Knowledge (PA) and Pain Management Beliefs and Knowledge (PM). In our proposed mental model framework, PA and PM affect the

ways caregivers answer two PA-related questions (Is there a problem?, Is this problem pain?) and three PM-related questions (Is the pain treatable?, Is it worth treating?, How do I prefer to treat it?). Caregivers are moved to action when they "connect the dots" by identifying a problem in PWDs' behavior, labeling the problem as pain, and identifying a response (i.e., a treatment approach) they consider worth trying. Disconnects in caregiver understanding of PWDs' behavior are common in this sample, and predictably lead to inaction. The proposed mental model provides further explanation about how caregivers do or do not synthesize and apply pain knowledge and experience, allowing for the identification of potential areas of intervention (e.g., pain psychoeducation) to improve pain treatment for the PWDs under their care.

DEVELOPMENT OF A MULTI-MODAL, DYADIC INTERVENTION FOR PERSISTENT PAIN: A QUALITATIVE STUDY

Aimee Fox,¹ Christine Fruhauf,² Jennifer Portz,³ Marieke Van Puymbroeck,⁴ Julia Sharp,² Heather Leach,² and Arlene Schmid,² 1. *Kansas State University, Manhattan, Kansas, United States*, 2. *Colorado State University, Fort Collins, Colorado, United States*, 3. *University of Colorado, Aurora, Colorado, United States*, 4. *Clemson University, Clemson, South Carolina, United States*

People who experience persistent pain often require help from a family member, partner, or friend. These caregivers frequently have pain, but are often not included in interventions. Caregivers and care-receivers who both experience pain are more likely to be socially isolated, experience communication conflict, and have decreased quality of life. Interventions should target caregiving dyads to help them manage their pain together. Feasibility studies that include manual development, intervention evaluation, and refinement of intervention manuals support randomized controlled trials and help move interventions from research to practice. Thus, the purpose of this qualitative study was to explore (a) the needs of caregiving dyads, (b) input from medical and allied health experts, and (c) feedback from intervention facilitators and evaluators, informing the development and refinement of an intervention manual for people with persistent pain. A total of 16 caregiving dyads and one individual (caregiver couldn't participate) experiencing pain participated in focus groups. Eight experts then participated in a focus group or one-on-one interview. Lastly, after the intervention ended, 15 intervention facilitators and fidelity evaluators participated in one focus group. Data were uploaded into NVivo software and analyzed using constant comparison. Findings identified the importance of interventions to focus on pain interference, novel and modifiable approaches to managing pain as a dyad, and addressing the emotional and psychological effects of experiencing pain. Using qualitative approaches to develop, test, and refine an intervention manual enhances the relevancy, acceptability, and translation of our intervention to meet the needs of caregiving dyads experiencing pain.

GENDER DIFFERENCES IN PAIN: EXAMINING EXPLANATIONS FOR THE ASSOCIATION

Cherish Michael, and Anne Barrett, *Florida State University, Tallahassee, Florida, United States*

Physical pain is a gendered experience: Women report higher levels of it than do men. This pattern may stem from differences in experiences of the body. Women are socialized to be attentive to its functioning, appearance, and sensations, while men are discouraged from paying much attention to their bodies. Little is known, however, about the precise social and economic pathways leading to gender differences in pain, especially in middle and later life when pain is most prevalent. We examine this issue using data from Wave 3 of Midlife in the United States (2013-2014). We consider four possible explanations for women's more frequent reports of pain: economic security, physical and mental health, social relationships, and discrimination. Results indicate that women are more likely than men to report experiencing chronic pain, as well as greater effects of it on their everyday lives. However, only two of the explanations contributed to explaining this association. Economic security and physical and mental health accounted for substantial portions of the association between gender and pain – 57 and 73 percent, respectively. In contrast, no mediating role was observed for either women's social relationships, in particular the greater strain they experience in them, or their more frequent reports of everyday and lifetime discrimination. The final model including all the possible explanations revealed that gender was no longer significant, suggesting that middle-aged and older women's greater pain is explained by their worse health and economic circumstances.

GENDER DIFFERENCES IN THE RELATIONSHIP BETWEEN COPING STYLE AND ATTITUDES TOWARDS PALLIATIVE CARE

Ilana Engel,¹ Amber Watts,² Tamara Baker,³ and Christian Sinclair,⁴ 1. *University of Kansas, Kansas, City, Missouri, United States*, 2. *University of Kansas, Lawrence, Kansas, United States*, 3. *University of North Carolina, Chapel Hill School of Medicine, University of North Carolina at Chapel Hill (School of Medicine), North Carolina, United States*, 4. *University of Kansas Medical Center, University of Kansas Medical Center, Kansas, United States*

Palliative care (PC) is becoming more widely available and its benefits, including improved quality of life for patients, have been demonstrated. Studies on patient-level barriers to PC access focus on knowledge and misperceptions. This study aimed to explore, among a community sample, whether more approach-focused coping styles may be associated with more positive attitudes towards PC and whether more avoidant coping styles are associated with more negative attitudes towards PC. Two linear regression analyses (an approach model and an avoidance model) were conducted to determine predictors of attitudes towards PC, controlling for potential confounds. The sample consisted of 87 community-dwelling adults ages 65+ (mean age=72.72 (5.88); 56.32% = women; 86.21% = White). In both models, more knowledge of PC was associated with more positive attitudes towards PC ($\beta = .71, p < .01$). Coping by engaging more social support was significantly associated with more positive attitudes towards PC ($\beta = .54, p < .05$). Results demonstrated a significant interaction ($\beta = -1.24, p < .01$) such that women who endorsed high levels of disengaged coping reported more favorable attitudes towards PC than men who

endorsed high levels of disengaged coping. Results indicate the need for a tailored approach to PC education for patients and families. Men who often cope with a stressor via distraction, self-blame, denial, or giving up may be less receptive to acceptance of PC. Future research on educational interventions tailored for individuals with distinct coping styles may be beneficial, particularly for men who frequently rely on disengaged coping styles.

IMPROVING QUALITY OF CARE VIA EFFECTIVE PAIN MANAGEMENT

Jennifer Rose, *The College of St. Scholastica, Foxboro, Wisconsin, United States*

Pain is neither a vital sign nor a normal part of aging. Yet, older adults frequently experience pain chronically or from an acute event. Pain was identified as a gap per the Centers for Medicare & Medicaid Services Quality Measures report (2019). The purpose of this quality improvement project was to improve the assessment of pain at a skilled nursing facility (SNF) by using a standardized tool. The Comprehensive Pain Assessment Tool for the Cognitively Intact evaluates the complex sensation and emotional reaction of the pain experience. Nurse managers (N=7) received 1:1 education on pain, pain assessment, use of the pain assessment tool, and took a post-test. Chart audits were conducted to identify tool use and evaluate the patient response. Additional data were collected from nurse managers via a questionnaire. All nurse managers received education and completed the post-test. Pain assessments and care plans were completed for 100% of the SNF residents in the cohort (N=22). Follow-up assessments were completed on only 75% of the cohort. Of the cohort, 95% demonstrated improved physical ability and functioning in activities of daily living as their pain experience improved. Only 4.5% of the cohort participated in the anticipated level of minutes of therapy as a result of facility infection control limitations due to the COVID-19 pandemic. This project demonstrated improved pain management through use of a tool to comprehensively assess pain. An organizational policy to comprehensively assess pain at this SNF could promote a higher level of independence and functioning for older adults.

INSTITUTIONAL EFFECTS ON EARLY PALLIATIVE CARE AMONG MEXICAN-HERITAGE ELDERS

Susan Miller,¹ and Ester Carolina Apesoa-Varano,² 1. *UC Davis*, 2. *UC Davis, Sacramento, California, United States*

This paper addresses Mexican-heritage older people's experiences with early palliative care (EPC). EPC is the early provision of medical, social and spiritual reports to relieve suffering. Empirically, Mexican-heritage older people are known to have less access to EPC and, when they access it, to receive care of lower quality. However, little work has explored how Mexican-heritage older people think about and access such care. The paper addresses this gap. Methods are longitudinal: 36 Mexican-heritage people ranging in age from 55 to 90 years completed longitudinal semi-structured qualitative interviews, for a total of 69 interviews. Results explore how respondents' participation in social institutions may mediate the effects of larger social structural constraints on their health and access to care.

KEEP YOUR HOPES UP: AN EXAMINATION OF RACIAL DIFFERENCES IN THE ASSOCIATION BETWEEN HOPE AND PAIN

Kyrsten Hill,¹ Emily Behrens,² Dylan Smith,³ Jason DeCaro,⁴ Brian Cox,⁴ and Patricia Parmelee,⁵ 1. *The University of Alabama, Tuscaloosa, Alabama, United States*, 2. *University of Alabama, Alabama, United States*, 3. *Stony Brook University, Stony Brook, New York, United States*, 4. *University of Alabama, Tuscaloosa, Alabama, United States*, 5. *University of Alabama, University of Alabama, Alabama, United States*

Hope has been associated with increased pain tolerance (Snyder et al., 2005) and has been incorporated in interventions targeting chronic pain (Howell et al., 2015; Katsimigos et al., 2020). Research suggests that African Americans with osteoarthritis (OA) pain experience greater pain severity and disability compared to non-Hispanic White individuals (Vaughn et al., 2019). Although the literature is limited, there is some evidence to suggest racial/ethnic differences in hope (Chang & Banks, 2007). The current study examined race as a moderator of the association between hope and pain in a sample of older adults. Experience sampling (ESM) data was used from a multi-site study examining non-Hispanic White and African American individuals with knee osteoarthritis (OA). Participants completed the Adult Hope Scale (Snyder et al., 1991) during baseline interviews and self-reported momentary pain during 28 ESM calls. Multilevel models revealed a significant interaction between hope and race ($p = .04$). Specifically, greater hope was associated with decreased momentary pain, and this association was stronger for African American compared to non-Hispanic White individuals. Results suggest that high levels of hope may be particularly protective for African American chronic pain patients. These findings can help inform existing and future interventions focused on enhancing hope in chronic pain populations. (Supported by AG041655, P. Parmelee and D. Smith, Co-PIs)

LONELINESS PREDICTS DEVELOPMENT OF PAIN, FATIGUE, AND DEPRESSION IN OLDER ADULTS

Victoria Powell, Navasuja Kumar, Mohammed Kabeto, Andrzej Galecki, Daniel Clauw, and Maria Silveira, *University of Michigan, Ann Arbor, Michigan, United States*

Pain, fatigue, and depression form a well-recognized symptom cluster that is posited to have a shared mechanism. It is possible that chronic psychosocial stressors such as loneliness may impact the central nervous system and immune system, potentially leading to symptom cluster development. Loneliness is an increasingly recognized type of psychosocial stress, especially among older American adults. Thus, we investigated whether loneliness increased risk of developing the symptom cluster of pain, fatigue, and depression over time. Using Health and Retirement Study data from 2006 – 2016, we examined self-respondents ≥ 50 years-old for the presence of co-occurring pain, fatigue, and depressive symptoms surpassing threshold levels (ie., the symptom cluster). Loneliness (measured by the 3-item UCLA Loneliness Scale) at baseline was used as the predictor of interest. Of the total sample ($n=11,766$), $n=5,956$ (50.6%) had up to two complete sets of follow-up symptom cluster measurements. Logistic regression models for longitudinal data were fitted using a

generalized estimating equation (GEE). After adjusting for demographic and clinical variables, loneliness strongly predicted the development of the symptom cluster (adjusted OR=3.16 (95% CI 2.77, 3.61)) as well as each component symptom (pain adjusted OR=1.54 (95% CI 1.42, 1.67); fatigue adjusted OR=1.88 (95% CI 1.74, 2.03); depression adjusted OR = 3.87 (95% CI 3.55, 4.21). Further research should investigate whether interventions targeting loneliness or other psychosocial stressors may have a role in prevention of this symptom cluster.

PAIN INTERFERENCE AND CONSCIENTIOUSNESS IN OLDER ADULTS

Stephanie Judge,¹ Kaitlyn Meyer,² and Suzanne Segerstrom,¹ 1. *University of Kentucky, Lexington, Kentucky, United States*, 2. *University of Kentucky, University of Kentucky, Kentucky, United States*

Pain interference increases with age and occurs when pain interrupts daily activities. Individuals vary in their amount of interference at a given level of pain. Conscientiousness is a personality trait characterized by diligence, perseverance, and goal-directedness, and is associated with fewer unhealthy behaviors and better health, including less pain and fewer functional limitations. This study tested three hypotheses on the relationships between pain, Conscientiousness, and pain interference among community-dwelling older adults ($N=210$) in a longitudinal study. At semi-annual interviews, participants reported their pain and interference. Conscientiousness was measured at baseline and follow-up. Multilevel models tested the between- and within-person relationships among study variables. Greater pain predicted more interference (person: $\gamma_{01}=.541$, $SE=.042$, $p<.0001$; visit: $\gamma_{10}=.495$, $SE=.014$, $p<.0001$) but higher Conscientiousness decreased interference ($\gamma_{02}=-.156$, $SE=.064$, $p<.025$). There was an interaction between Conscientiousness and pain: At higher levels of pain, older adults higher in Conscientiousness experienced much less interference than their less conscientious peers ($\gamma_{11}=-.199$, $SE=.089$, $p<.025$). Older age at baseline predicted a greater decrease in Conscientiousness over the study period ($b=-0.013$, $t(91)=-2.07$, $p<.05$). Conscientiousness reduces the negative impact of pain on daily function. This protective effect may reflect perseverance and commitment to valued activities, consistency with proactive health behaviors, or other attitudes and behaviors that reduce the likelihood of psychosocial sequelae of pain. Overall, the sample decreased in Conscientiousness over time; however, the direction and amount of change varied considerably. These results refine existing knowledge of personality in old age and implicate personality factors as a potential target for pain management.

SELF-REPORTED PAIN AND SYMPTOMS IN COMMUNITY DWELLING OLDER ADULTS: RESULTS FROM THE STUDY OF AGING II

Kristen Allen-Watts,¹ Deanna Rumble,¹ Cynthia Brown,² and Richard Kennedy,¹ 1. *University of Alabama at Birmingham, Birmingham, Alabama, United States*, 2. *Louisiana State University Health Sciences Center - New Orleans, New Orleans, Louisiana, United States*

Pain is a common concern for community-dwelling older adults. There are a range of symptoms that may occur with

pain that can be recurring and severe, which are associated with decreased quality of life. This study aims to characterize overall symptom load by utilizing the Brief Symptom Scale in community dwelling older adults who experience mild to severe pain. Data were extracted from the UAB Study of Aging II, a prospective, population-based study of mobility among community-dwelling older adults 75 years and older. Self-reported pain in the past 4 weeks and symptoms (e.g., pain, tired, nausea, depression, anxiety, shortness of breath) were included. The SPSS version 27.0 statistical package was used for analysis. Sixty-six percent were Non-Hispanic White, 58% were female, 40% lived in housing designed especially for the disabled, 49% were widowed, and 30% had a High School degree or GED. The mean age was 81 years (standard deviation 4.8). Of interest, over one third of the sample (38.1%) experienced moderate to severe pain, upper back pain was the most common area where pain occurred and feeling tired was the most common symptom. As the aging population continues to increase, so will the prevalence rates for pain. Findings suggests older adults with pain have multiple concomitant symptoms. Because the elderly represents a fragile and large group of the population, it is important to pay close attention to these symptoms.

THE MODERATING ROLE OF DEPRESSION ON MOMENTARY PAIN-AFFECT ASSOCIATIONS IN OSTEOARTHRITIS

Emily Behrens,¹ Kyrsten Hill,² Dylan Smith,³ Jason DeCaro,⁴ Brian Cox,⁴ and Patricia Parmelee,⁵
 1. *University of Alabama, Alabama, United States*, 2. *The University of Alabama, Tuscaloosa, Alabama, United States*, 3. *Stony Brook University, Stony Brook, New York, United States*, 4. *University of Alabama, Tuscaloosa, Alabama, United States*, 5. *University of Alabama, University of Alabama, Alabama, United States*

Previous research has found a reciprocal relationship between pain and depression, in which each influences the severity of the other (Chou, 2007; Hawker et al., 2011, Kroenke et al., 2011; Schieir et al., 2009). Studies have found that depressed individuals exhibit stronger pain-mood associations than never-depressed individuals (Conner et al., 2006; Tennen et al., 2006). The current study investigated main and interactive effects of depressive symptoms on the momentary associations between pain and mood. Experience sampling (ESM) data was used from a multi-site study examining individuals with knee osteoarthritis (OA). Participants completed self-report measures of global depression and momentary pain, negative affect (NA), and positive affect (PA). Cross-sectional associations among momentary pain and affect were examined in a series of hierarchical multilevel models that nested the 28 ESM calls (Level 1) within participants (Level 2). A parallel set of multilevel models tested lagged associations among momentary variables. Depression significantly moderated the contemporaneous ($p < .001$) and lagged ($p < .003$) associations between pain and NA, suggesting that depression intensifies the momentary pain-NA linkage. There were no significant interaction effects for PA. These findings extend existing knowledge by illustrating how depressive symptoms influence the everyday experience of OA pain and its impact on affective well-being. (Supported by AG041655, P. Parmelee and D. Smith, Co-PIs)

Session 9415 (Poster)

Personality

A COORDINATED ANALYSIS EXAMINING THE ASSOCIATION BETWEEN PERSONALITY TRAITS AND COGNITIVE DISPERSION

Tomiko Yoneda,¹ Alejandra Marroig,² Emily Willroth,³ Eileen Graham,³ Scott Hofer,¹ Daniel Mroczek,³ and Graciela Muniz-Terrera,⁴ 1. *University of Victoria, Victoria, British Columbia, Canada*, 2. *Universidad de la República, Uruguay, Instituto de Estadística, Universidad de la República, Montevideo, Uruguay*, 3. *Northwestern University, Chicago, Illinois, United States*, 4. *University of Edinburgh, Edinburgh, Scotland, United Kingdom*

Cognitive dispersion is the degree of within-person variation in performance across cognitive tasks at the same testing occasion. Existing literature indicates that cognitive dispersion may be an early marker of poor brain health, dementia and mortality. Limited research, however, has examined individual differences in cognitive dispersion. Although personality traits are associated with individual differences in cognitive functioning, no research has examined personality and cognitive dispersion. In this project, we execute a pre-registered, coordinated analysis of seven diverse, international longitudinal studies of aging (Ntotal=33,581; mean age range=56.4-71.2) to investigate the extent to which the Big Five personality traits are associated with cognitive dispersion. For methodological approach, see osf.io/wrnjq/. Cognitive dispersion scores were derived from cognitive test results, and independent linear regression models were fit independently in each study to examine personality traits as predictors of dispersion scores, adjusting for mean cognitive performance and socio-demographics (age, sex, education). Results from individual studies were synthesized using random-effects meta-analyses. Results revealed minimal evidence for associations between cognitive dispersion and personality traits in independent analyses or in meta-analyses. Based on the meta-analytic estimates, only higher levels of openness were associated with greater cognitive dispersion. Mean cognitive scores were negatively associated with cognitive dispersion across the majority of studies, indicating that individuals with higher mean performance had less dispersed cognitive scores. Our study contributes to the replicability and transparency efforts characteristic of open science by pre-registering our study and drawing on the collaborative network of the Integrative Analysis of Longitudinal Studies of Aging and Dementia (IALSA).

IMPACT OF PERSONALITY FEATURES AND INTERPERSONAL PROBLEMS ON ANXIETY AMONG OLDER ADULTS

Olivia Noel,¹ Daniel Segal,² Katie Granier,³ Marissa Pifer,³ and Lisa Stone,³ 1. *Peak View Behavioral Health, Colorado Springs, Colorado, United States*, 2. *University of Colorado at Colorado Springs, University of Colorado at Colorado Springs, Colorado, United States*, 3. *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*

Introduction: Anxiety is a significant mental health problem among older adults and is associated with multiple other mental disorders, poor psychosocial functioning, and reduced quality of life. Personality traits and disorders, along with interpersonal problems, may play a significant role in anxiety, but these relationships are not well understood among older adults. This study examined relationships between anxiety with normative personality traits, personality disorder (PD) features, and interpersonal problems. **Method:** Community-dwelling older adults (N = 130) completed the Geriatric Anxiety Scale (GAS), Coolidge Axis Two Inventory (CATI), Big Five Inventory-2 (BFI-2), and Circumplex Scales of Interpersonal Problems (CSIP). **Results:** Anxiety was positively correlated with 13 of 14 CATI PD scales, ranging from .23 (Narcissistic) to .61 (Depressive). Regarding normative personality, anxiety was associated with Agreeableness (-.23), Conscientiousness (-.30), Extraversion (-.31), and Negative Emotionality (.56). Regarding interpersonal problems, anxiety was positively related to all eight CSIP scales: Self-Sacrificing (.30), Domineering (.31), Exploitable (.40), Intrusive (.41), Self-centered (.47), Nonassertive (.50), Socially Inhibited (.60), and Distant/Cold (.62). Regression analyses indicated that PD features accounted for the most variance in anxiety (53%), followed by interpersonal problems, (46%) and normative personality traits (33%). **Discussion:** Anxiety appears to be meaningfully associated with PD features, several aspects of normative personality, and interpersonal problems, suggesting that these variables may play a role in the development of anxiety, or vice versa. Our findings especially speak to the growing awareness of the deleterious impact of PD features on clinical syndromes in later life, as evidenced by strong comorbidities with anxiety.

PATHOLOGICAL TRAITS AND INTERPERSONAL DIFFICULTIES IN DEPRESSED OLDER ADULTS: CLINICAL VERSUS COMMUNITY SAMPLING

George Lederer,¹ David Freedman,² Lauren Atlas,³ Shira Kafker,⁴ Ira Yenke,⁴ Angel Mak,⁴ Dimitry Francois,⁵ and Richard Zweig,⁴ 1. *Jacobi Medical Center, Scarsdale, New York, United States*, 2. *Lenox Hill Hospital, Brooklyn, New York, United States*, 3. *New York-Presbyterian/Columbia University Irving Medical Center, NEW YORK, New York, United States*, 4. *Yeshiva University, Bronx, New York, United States*, 5. *NY, White Plains, New York, United States*

Personality pathology, represented by high neuroticism and low agreeableness in the Five Factor Model of Personality, has been identified as a predictor of depression in mixed-age samples and preliminary studies of older adults. Research on older people, however, has not examined the differential impact of pathological personality traits and processes on depression or examined them across treatment settings. This secondary analysis examined personality traits and processes as predictors of depression, evaluated the moderating effect of interpersonal problems, and assessed stratification of these personality variables across community and clinical settings. Older adults (N=395) ranging in age from 55 to 99 (M = 72.06; SD = 10.10) from inpatient psychiatric, outpatient medical, and community settings completed self-report measures of personality traits (NEO-FFI Agreeableness and Neuroticism), processes (Inventory of Interpersonal Problems), and depression (GDS-30). Higher neuroticism

predicted worsened depressive symptoms ($\beta = .765$, $p < .001$), as did lower agreeableness ($\beta = -.163$, $p = .002$) and more interpersonal problems ($\beta = .459$, $p < .001$). Findings partially supported the stratification of personality traits and processes by setting. Interpersonal problems moderated neither the neuroticism-depression or agreeableness-depression relationships. Personality traits and processes predict depression in older adults across care settings but do not significantly interact. Levels of pathological traits and processes vary across community and clinical settings.

PERSONALITY CHANGE PROFILES AND CHANGES IN COGNITION AMONG MIDDLE-AGED AND OLDER ADULTS

Mirjam Stieger,¹ Yujun Liu,² Eileen Graham,³ Jenna DeFrancisco,¹ and Margie Lachman,⁴ 1. *Brandeis University, Waltham, Massachusetts, United States*, 2. *Northern Illinois University, Naperville, Illinois, United States*, 3. *Northwestern University, Chicago, Illinois, United States*, 4. *Brandeis University, Brandeis University, Massachusetts, United States*

Previous research on the relationship between personality traits and cognitive abilities has primarily focused on cross-sectional studies or on specific personality traits in relation to selected cognitive dimensions. The present study extends existing research by exploring associations among 20-year personality change profiles and 10-year cognitive change in middle-aged and older adults. The present study included 2,652 participants of the Midlife in the United States study (MIDUS) ranging in age between 20 - 74 years (M = 46.61, SD = 11.26) at the first of the three measurement occasions. Latent Profile Analysis (LPA) was used to capture profiles of change across the Big Five personality traits of extraversion, conscientiousness, agreeableness, openness, and emotional stability combined. Results of the LPA identified three personality change subgroups: Decreasers, Maintainers, and Increases. Across the 20 years, the Decreasers showed greater decreases on the Big Five personality traits, the Maintainers remained mostly stable, and the Increases showed greater personality trait increases. Also, the Maintainers and Decreasers were significantly older than the Increases. Longitudinal multilevel models were used to examine the relationship between these three personality change profiles and cognitive change. Age, sex, education, physical activity, functional health, and self-rated health were added as covariates. Results show that cognitive decline was greater for the Decreasers and less for the Increases compared to the other personality change profiles. The results have implications for developing interventions to target personality trait change in middle and later adulthood as a potential means for reducing declines in cognitive functioning.

THE INTERPERSONAL CIRCUMPLEX AND THE ALTERNATIVE MODEL OF PERSONALITY DISORDERS: RELATIONSHIPS AMONG OLDER ADULTS

Lisa Stone,¹ and Daniel Segal,² 1. *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*, 2. *University of Colorado at Colorado Springs, University of Colorado at Colorado Springs, Colorado, United States*

Introduction: The interpersonal circumplex model measures interpersonal dysfunction along two axes (community and agency), resulting in eight unhealthy patterns: Domineering, Vindictive, Cold, Socially Avoidant, Nonassertive, Exploitable, Overly Nurturant, and Intrusive. It is unclear how the circumplex model applies to older adults and their unique biopsychosocial contexts. This study examined relationships between the circumplex and personality disorder features, using the Alternative Model of Personality Disorder's (AMPD) personality functioning and pathological personality trait constructs. **Method:** Older adults (N = 202) completed the Inventory of Interpersonal Problems-Short Circumplex (IIP-SC), the Levels of Personality Functioning Scale-Self-Report (LPFS-SR), and the Personality Inventory for DSM-5 (PID-5) to measure pathological personality traits. **Results:** Correlations were computed between the IIP-SC's eight circumplex scales with the LPFS-SR's four personality functioning domains and with the PID-5's five domains. All circumplex scales significantly ($p < .001$) and positively correlated with all LPFS-SR and PID-5 domains, with large effect sizes ($> .45$). Next, regressions were conducted, with the LPFS-SR and PID-5 domains predicting each IIP-SC scale. Across the eight regressions, the AMPD constructs accounted for significant variance in the IIP-SC scales, ranging from 38% (Nonassertive) to 64% (Domineering and Cold). **Discussion:** Significant overlap between the interpersonal circumplex and the AMPD was demonstrated, but patterns are distinct from previous research among younger adults. The circumplex was limited in its relation to the AMPD's personality functioning, but the pathological personality trait model was well represented through the circumplex. Results indicate that the circumplex may have some validity among older adults and warrants further investigation.

Session 9420 (Poster)

Physical Activity and Exercise

ACTIGRAPHY MEASURED PHYSICAL ACTIVITY ON COGNITIVE FUNCTIONING IN OLDER ADULTS

Pilar Thangwaritorn, and Amber Watts, *University of Kansas, Lawrence, Kansas, United States*

Physical activity may preserve cognitive functioning in older adults. This study examined associations between objectively measured physical activity and cognitive functioning. We recruited participants (Mage = 75.38 years, SD = 5.99) with (N=26) and without (N=181) cognitive impairment from the University of Kansas Alzheimer's Disease Center (KU-ADC). We collected cognitive data representing verbal memory, attention, and executive function. Accelerometers (Actigraph GT9X) were used to measure physical activity 24 hours a day for 7 days in a free-living environment. Physical activity was categorized as moderate to vigorous physical activity (MVPA) based on the Freedson (2011) Adult Vector Magnitude cut points. The association between cognitive functioning and total MVPA was evaluated by using multiple regression. We used factor analysis to create three composite scores (verbal memory, attention, executive function) from 11 individual cognitive tests. Compared to verbal memory and attention, results indicate that total MVPA was

more strongly associated with executive function ($\beta = 0.001$, $p = .024$). These findings are consistent with the literature suggesting that executive function in older adults may benefit from physical activity. Future research should investigate the physiological mechanisms by which MVPA benefits executive function in contrast to types of activity that might benefit verbal memory and attention.

AGE AND GENDER DIFFERENCES IN LONG-TERM EXERCISE BEHAVIOR FOR OLDER ADULTS WITH HEART DISEASE

Helen Graham,¹ Yuki Asakura,² and Kathy Prue-Owens,¹ *1. University of Colorado Colorado Springs, Colorado Springs, Colorado, United States, 2. Centura Health Penrose - St. Francis, Colorado Springs, Colorado, United States*

Exercise decreases mortality and hospital admissions. Exercise adherence is challenging, and little is known about exercise adherence especially in older adults with heart disease. To gain an understanding of long-term exercise behaviors in older adults we conducted a cross-sectional study of individuals diagnosed between 2016-2020 with myocardial infarction (MI)/angina. Emails were sent in 2020 to recruit participants. Exercise adherence was measured using the Exercise Adherence Rating Scale (EARS), Godin's Leisure-Time Activity Scale (GLTEQ) for exercise intensity, and self-report for impact of COVID-19. Descriptive statistics and t-tests were used to analyze data. Eight-hundred and seven individuals (\bar{x} age 67.3) responded to the on-line survey. The majority were males (68.8%), married, (68.9%), and retired (59.3%). Co-morbidities included hypertension (32%), hyperlipidemia (21%), diabetes (12%), and depression (6.2%). Long-term exercise behaviors were independently observed in participants ≥ 65 yr (n=526) and < 65 yr (n=281). Females ≥ 65 yo demonstrated higher exercise adherence scores compared with males ≥ 65 yo (1.66 ± 1.1 vs. 1.30 ± 21.7 ; $t = -2.59$, $p = .010$). Conversely, males scored higher in exercise intensity (34.4 ± 24.7 vs. 22.6 ± 21.7 ; $t = 3.84$, $p = .000$). Gender related exercise adherence and exercise intensity did not differ significantly in < 65 yo ($p = .278$ & $p = .282$, respectively). Exercise frequency decreased in both age groups after COVID-19 Pandemic started, however the decrease was significant only in older adults ($p = .014$) indicating they were at greater risk for exercise problems when faced with environmental barriers. Additional research is recommended as to the impact of environmental factors on exercise adherence in older adults and potential interventions.

BIOMECHANISM AND EXERCISE EFFECT OF FITNESS WALKING USING TWIN WALKING STICKS

Ken Yamauchi,¹ Tsutomu Ichikawa,² Akira Ogita,³ Hironori Yoshida,⁴ Hiromichi Hasagawa,⁵ Hiroshi Matsui,⁶ and Shota Kagawa,⁷ *1. Keio University, Yokohama, Kanagawa, Japan, 2. Department of Early Childhood Education and Care, Matsuyama, Ehime, Japan, 3. Osaka City University, Osaka, Osaka, Japan, 4. Liberal Arts Education Center, Ashikaga, Tochigi, Japan, 5. Fitness center, Nagakute, Aichi, Japan, 6. Kyoto Medical Center, Kyoto, Kyoto, Japan, 7. Makuhari Human Care, Chiba, Chiba, Japan*

In Japan, walking poles with pairs of sticks developed exclusively for fitness walking have been designed. A new

concept of walking style (WS) has been conceived using these walking sticks to “effectively” walk around the city, comprehensive sports parks, or at rehabilitation hospitals. Stick manufacturers are promoting its health benefits; however, evidence supporting these claims is lacking. Hence, this study aimed to measure the influence of walking sticks and evaluate the exercise effect based on functional physical fitness related to WS characteristics. The participants were 12 WS instructors. They engaged in WS at a comfortable speed after walking normally at the same speed (WN) for ~5 m (seven times), followed by WS again. The walking speed, step length, stride width, walk ratio, one-leg support time, and trajectory of the center of gravity (CG) (in the horizontal and vertical directions of one walking cycle) calculated from the whole-body skeleton model were analyzed. The gait of WS increased the step length, step width, and walking ratio as compared with that of WN ($p < 0.05$). WS likely reduce cadence and one-leg support time ($p < 0.05$). The CG locus in the left-right direction showed no significant differences between WS and WN. The maximum value of the CG locus in the vertical direction was high in WS ($p < 0.05$). WS can be used as a navigation training tool that improves a walker's exercise efficiency and left-right leg coordination, thereby improving walking posture. This may help reduce the anxiety due to injuries and pain that may occur while walking.

CAREGIVERS' PERCEPTION ABOUT THEIR PARTICIPATION IN A COMMUNITY-BASED EXERCISE INTERVENTION - BODY & BRAIN PROJECT

Oscar Ribeiro,¹ Pedro Marques,² Duarte Barros,³ Paula Silva,³ Joana Carvalho,³ and

Flávia Borges-Machado,³ 1. *University of Aveiro, University of Aveiro, Aveiro, Portugal*, 2. *Department of Education and Psychology, University of Aveiro, University of Aveiro, Aveiro, Portugal*, 3. *Research Centre in Physical Activity, Health and Leisure (CIAFEL), Faculty of Sports, University of Porto, University of Porto, Porto, Portugal*

Evidence is scarce on caregivers' perception regarding their participation in exercise interventions targeting individuals with neurocognitive disorder (NCD). This study aims to investigate the views of family caregivers of people with NCD about taking part in a community-based physical exercise intervention with their care-recipients. Twenty caregivers (N Male: 13; 66.5 ± 14.39 years old; age range: 36-88) answered to a semi-structured interview conducted by telephone about their perception on participating or not as class members of a 6-month multicomponent training intervention. Transcribed data from the interview were analyzed through thematic analysis. Main themes regard their perceived key-role in the care recipients' participation, which included knowing their limitations, making them feel accompanied and motivated, and the possibility of providing comfort and tranquility throughout the intervention. Caregivers also mentioned the possibility of fulfilling own needs for physical activity and being engaged in new experiences. Disturbing the care recipients' involvement and performance, the opportunity for respite during the sessions' time, and being enrolled in the program only in specific moments or by telephone were also mentioned. Findings highlight the inclusive perspective of caregivers to take part of exercise programs designed for people with NCD, not only due to

their decisive role on care-recipients engagement but also due to the associated (in-/)direct personal benefits. This data may be useful for planning and prescribing future community-based exercise interventions for NCD caregiving dyads. Trial registration: ClinicalTrials.gov - NCT04095962. Supported by FCT: “Body and Brain” (POCI-01-0145-FEDER-031808), CIAFEL (FCT/UIDB/00617/2020), and Ph.D. Grants (SFRH/BD/136635/2018) to FM (2020.05911.BD) to DB.

CREATION AND PILOT TESTING OF THE CONFIDENCE TO ENGAGE IN PHYSICAL THERAPY IN OLDER ADULTS (CEPT) MEASURE

Patricia Bamonti,¹ Rebekah Harris,² Jennifer Moye,¹ and Jonathan Bean,² 1. *VA Boston Healthcare System, Boston, Massachusetts, United States*, 2. *VA Boston Healthcare System, VA Boston Healthcare System, Massachusetts, United States*

The measurement of self-efficacy is important in physical therapy (PT) settings where patients face barriers and adoption of new behavior is critical for recovery. However, existing measures of exercise self-efficacy do not account for the internal (i.e., fatigue) and external (i.e., scheduling) barriers to self-efficacy observed in older adults. We developed a self-report measure assessing an individual's confidence to engage in PT despite barriers. Qualitative ratings from patients (N = 75; age M = 78.26 ± 11.2 ; 80% white; 20% African American) enrolled in PT at a Veterans Affairs Medical Center (VAMC) and their physical therapist were used to create a 21-item pool for the Confidence to Engage in Physical Therapy in Older Adults (CEPT). We next evaluated item characteristics and scale reliability and validity of the CEPT in a new sample of patients (N = 19; age M = 81.11 ± 8.93 ; 88.8% white, 11.1% African American) enrolled in an outpatient PT program who also received the Geriatric Depression Scale-15 (GDS-15), and the Activities-specific Balance (ABC) Scale. Response choice ranged from 0% (not confident at all) to 100% (highly confident) with higher scores indicating greater self-efficacy. Item analyses indicated adequate response variability across items (M = 55.9 ± 24.80 , range 10-85). The scale demonstrated evidence of internal consistency reliability (Cronbach's alpha) = 0.98. Construct validity was demonstrated by positive association between CEPT and the ABC ($r = .74$, $p < .001$) and negative association with GDS-15 ($r = -.64$, $p < .01$). The CEPT requires further evaluation with larger sample sizes.

DOES A 6-MONTH MULTICOMPONENT TRAINING IMPROVE FUNCTIONAL CAPACITY OF INDIVIDUALS WITH A NEUROCOGNITIVE DISORDER?

Oscar Ribeiro,¹ Flávia Borges-Machado,² Duarte Barros,² Laetitia Teixeira,³ and Joana Carvalho,² 1. *University of Aveiro, University of Aveiro, Aveiro, Portugal*, 2. *Research Centre in Physical Activity, Health and Leisure (CIAFEL), Faculty of Sports, University of Porto, University of Porto, Porto, Portugal*, 3. *ICBAS.UP, ICBAS.UP, Porto, Portugal*

Regular physical activity and exercise have been proposed as non-pharmacological therapeutic approaches to prevent and manage neurocognitive disorders (NCD). Multicomponent training (MT) combining aerobics, strength, postural and balance exercises seem to be effective at improving individuals with NCD in their ability to

independently perform activities of daily living (ADL). This quasi-experimental controlled trial aims to analyze the effects of a 6-month MT intervention on functional capacity of individuals diagnosed with NCD. Forty-three subjects (N Major NCD: 36) participated in the Body&Brain Project and were subdivided in exercise group (EG; N: 23; 75.09 ± 5.65 years; age range: 61-83) or a control group (CG; N:20; 81.90 ± 5.95 years; age range: 70-89). The EG was submitted to bi-weekly exercise sessions, and the CG received monthly recreation sessions. At baseline and at post-intervention Timed-Up-and-Go (TUG), 6-meters Walk Speed and Handgrip tests were applied to evaluate lower body mobility, walking speed and handgrip strength, respectively. Results from linear mixed models revealed a statistically significant interaction between group (intervention vs. control) and time for TUG and walk speed test, but not for handgrip strength. The 6-month MT intervention improved lower body mobility and walking speed of older adults diagnosed with NCD, which might potentially impact ADL independence and quality of life. Trial registration: ClinicalTrials.gov - NCT04095962. Supported by FCT: "Body and Brain" (POCI-01-0145-FEDER-031808), CIAFEL (FCT/UIDB/00617/2020), and Ph.D. Grants (SFRH/BD/136635/2018) to FM and [2020.05911.BD] to DB.

DUAL-TASK COSTS IN GAIT SPEED DIFFERS ACROSS AGE GROUPS

Sally Paulson,¹ Michelle Gray,² Joshua Gills,² Anthony Campitelli,² Megan Jones,² Joohee Sanders,³ Erica Madero,⁴ and Jordan Glenn,⁴ 1. *University of Arkansas at Fayetteville, Cincinnati, Ohio, United States*, 2. *University of Arkansas at Fayetteville, Fayetteville, Arkansas, United States*, 3. *Shippensburg University of PA, Shippensburg, Pennsylvania, United States*, 4. *Neurotrack Technologies, Redwood City, California, United States*

With age, there are simultaneous reductions in gait speed (GS). This decrease in GS has been associated with an increased fall risk and negatively impacts independence. Further, GS naturally declines with the addition of a secondary stimulus (i.e., cognitive requirements). Combined, these decrements can be additive in nature potentially leading to robust declines with advancing age. Therefore, the aim of this study was to examine age-related effects of dual-task cost (DTC) while walking. Adults (N = 145), over the age of 45 years, completed two walking trials for each GS condition: habitual (HAB) and fast (FST), with and without a DT (i.e., counting backwards by serials of three). Subjects were classified into four age groups: youngest-old (YG ≤ 64 years, n = 24), young-old (YO, 65-74 years, n = 46), middle-old (MO = 75-84 years, n = 54), and oldest-old (OO ≥ 85 years, n = 21). DTC was calculated and ANOVAs were used to assess differences between the groups. There was no difference in HAB DTC between the age groups (p=.61). However, there was a significant difference in FST DTC (p=.04) between the YO (M±SD: -14 ± -11%) and OO (M±SD: -24 ± -12%). These data indicate there was an age-related affect for fast dual-task cost, but not for habitual dual-task cost while walking. An increase in dual-task cost among the oldest-old may be associated with an inability to properly maintain a faster cadence while performing an arithmetic task which may be related to task prioritization.

EFFECT OF HIGH-INTENSITY INTERVAL TRAINING ON RHEUMATOID ARTHRITIS CD4+ T CELL OXIDATIVE METABOLISM

Brian Andonian,¹ David Bartlett,² Nancie MacIver,² William Kraus,² and Kim Huffman,² 1. *Duke University School of Medicine, Durham, North Carolina, United States*, 2. *Duke University, Durham, North Carolina, United States*

Persons with rheumatoid arthritis (RA) have poor cardiorespiratory fitness and accelerated biological aging driven by systemic impairments in metabolism and inflammation. In this study of older RA participants, our goal was to identify the effects of a high-intensity interval training (HIIT) program on cardiorespiratory fitness and peripheral CD4+ T cell metabolism. We isolated CD4+ T cells from peripheral blood mononuclear cells in sedentary female RA participants (n=6; age=64.0±/6.3 years) who underwent cardiopulmonary exercise testing and phlebotomy before and after 10 weeks of HIIT. HIIT improved RA cardiorespiratory fitness by 6.5±/6.0% (pre-HIIT VO₂ peak=25.1±/5.1 ml/kg/min, post-HIIT VO₂ peak=26.7±/5.0; p=0.05). As measured by Seahorse XF Mito Stress Test, there were no significant mean changes in CD4+ T cell oxidative (oxygen consumption rate (OCR); pmol/min) or glycolytic (extracellular acidification rate (ECAR); mpH/min) metabolism, however there was large interindividual variability. RA peripheral CD4+ T cells preferred glycolytic metabolism (pre-HIIT mean basal OCR/ECAR ratio=0.78±/0.13 pmol/mpH), while HIIT non-significantly shifted cellular preference toward oxidative metabolism (post-HIIT mean basal OCR/ECAR ratio=0.86±/0.16; p=0.30). Increases in RA cardiorespiratory fitness following HIIT were significantly associated with increases in RA peripheral CD4+ T cell OCR/ECAR ratio (Spearman's rho=1.0, p<0.001) and basal and maximal respiration (rho=0.89, p=0.02 for both). Additionally, increases in CD4+ T cell mitochondrial ATP-linked respiration were significantly associated with increased quantities of circulating naïve CD4+CCR7+CD45RA+ T cells (rho=0.89, p=0.02). Our findings suggest that targeting cardiorespiratory fitness may be key in modulating T cell specific oxidative metabolism and function to prevent immunosenescence in older patients with chronic inflammatory diseases.

EFFECT OF VIDEO ASSISTED HOME-BASED EXERCISE INTERVENTION ON FALL RISK AND GAIT PARAMETERS IN OLDER ADULTS IN INDIA

Snehal Kulkarni, and Aarti Nagarkar, *Savitribai Phule Pune University, Pune, Maharashtra, India*

Countries across the globe recommended isolation to protect older adults from COVID-19 infection. However, this led to decreased mobility and physical inactivity potentially increasing their risk of fall. The study was conducted in a group of 88 older adults between 60-74 years with known gait impairments and high fall risk. The participants were part of our cohort study on fall prevention program. Fall risk and gait impairments were measured using wearable sensors during the Timed-up and go test (TUG) at baseline. Using technology, a 16-week video assisted home based exercises intervention was delivered to reduce fall risk and improve gait parameters. The intervention consisted of flexibility, strengthening, balance and gait training exercises given

progressively through one video session per week. The participants performed these exercises at home for the rest of the week. A home visit immediately after 16th week was arranged to collect post intervention parameters. Results showed an average 20% decrease in fall risk post intervention. An overall large effect size with Cohen's *d* of 0.90 was reported for fall risk. Significant difference in TUG time ($Z = -4.610$, $p < 0.000$), stride velocity ($Z = -5.035$, $p < 0.000$), stride length ($Z = -5.867$, $p < 0.000$), time taken to stand ($Z = -7.363$, $p < 0.000$) and time taken to turn ($Z = -6.079$, $p < 0.000$) was observed in the post-test measurements as compared to pre-test measurements. Therefore, we conclude that video assisted exercise programs can be highly beneficial as alternatives to in person exercise intervention to prevent falls during COVID-19 isolation.

EFFECTS OF DIFFERENT 16-WEEK EXERCISE INTERVENTIONS ON BONE MINERAL DENSITY OF SEDENTARY OLDER WOMEN

Amy Ellis,¹ Kristi Crowe-White,² and Gary Hunter,³

1. *University of Alabama, Tuscaloosa, Alabama, United States*, 2. *The University of Alabama, Tuscaloosa, Alabama, United States*, 3. *University of Alabama at Birmingham, Birmingham, Alabama, United States*

Multicomponent exercise that includes both resistance and aerobic training is recommended to prevent loss of bone mineral density (BMD) in postmenopausal women. However, optimal training frequency has not been determined. Sixty-three non-osteoporotic sedentary women ages 60y and older were randomized to one of three exercise groups for sixteen weeks: 1) one resistance and one aerobic session per week, 2) two resistance and two aerobic sessions per week, or 3) three resistance and three aerobic sessions per week. Resistance exercise included supervised sessions on weight machines, and aerobic exercise was treadmill walking. BMD of the hip and lumbar spine (L1-L4) was assessed by dual energy X-ray absorptiometry (Prodigy, GE Medical Systems Lunar, Madison, WI, software version 6.10.029), and *z* scores were calculated from a reference population adjusted for age and sex. Among the total cohort with BMD measurements at week 16 ($n=58$; 83% white), *z* scores improved for the trochanter, Ward's triangle, total hip, L1 and L4. Within-group comparisons showed improvement at the trochanter, total hip, and L1 for group 2 only, while only group 1 demonstrated an increase at L4 ($p < 0.05$ for all). However, no time-by-group interactions were observed. Sixteen weeks of combined resistance and aerobic training is effective for improving BMD of older adult women. Results suggest training frequency of two sessions per week may be optimal. Postmenopausal women should be encouraged to do aerobic exercise such as walking plus resistance training at least once weekly to prevent osteoporosis.

EFFECTS OF TAI CHI ON BIOMARKERS AND THEIR IMPLICATION TO NEUROREHABILITATION – A SYSTEMIC REVIEW

Howe Liu,¹ and Yasser Salem,² 1. *University of North Texas Health Science Center, Fort Worth, Texas, United States*, 2. *University of North Texas Health Science Center, Fort Worth, Texas, United States*

Introduction: As an effective holistic therapeutic exercise program, Tai Chi (TC) has been widely used for patients with

a variety of neurological disorders. In last 1-2 decades, there has been an increase in the number of research studies that examined the TC effects on biomarkers andIntroduction: As an effective holistic therapeutic exercise program, Tai Chi (TC) has been widely used for patients with a variety of neurological disorders. In last 1-2 decades, there has been an increase in the number of research studies that examined the TC effects on biomarkers including inflammatory cytokines, oxidative stressors, and neurotrophic factors. Thus, the purpose of this article is to review such effects and their possible implications to neurorehabilitation. Method: In this systematic review, we searched TC-related articles from the last 15 years until July 2020 that had investigated changes of biomarkers after TC practice. The search identified 24 studies that were included in our analysis. Results: It is found that TC practice is able to 1) reduce pro-inflammatory and increase anti-inflammatory cytokines (including Interleukins -1, 6, 10, 12, tumor necrosis factor, the nuclear factor kappa-light-chain-enhancer of activated B cells, and the C-reactive protein); 2) decrease oxidative stress factors (like plasma 8-isoprostane, malondialdehyde, and protein carbonylation); and 3) increase neurotrophic factors (brain-derived neurotrophic factor (BDNF), and N-Acetylaspartate). Conclusions: TC may take effect on patients with neurological dysfunctions through anti-inflammation, anti-oxidative stress, and neural health promotion.

FIT FOR THE NEXT FIFTY EXERCISE PROGRAM: 25 YEARS OF REFLECTIONS, RESULTS, AND PARTNERSHIPS

Mary Pagan, *SUNY Oswego, Baldwinsville, New York, United States*

Consistent exercise provides a multitude of physical, social, and emotional benefits. Common barriers to regular exercise for older adults include time, transportation, risk of injury, existing limitations, and negative experiences or attitudes about exercise. Fit for the Next Fifty is a comprehensive exercise and wellness program designed to address barriers and excuses. The program, based in CNY, has an impressive 25 year history of providing a unique mix of aerobic, strength training, yoga, and balance-based ballet. Participants (100-120) attend up to 5 classes per week at no charge during summer months and continue through winter months for a small fee. Developing and sustaining funding partnerships has been critical to the long-term success of Fit for the Next Fifty. Participants, ages 60-96, are active providers of feedback and suggestions, a key component to keeping the music, movements, and fellowship enjoyable and meaningful for over two decades. Program details, participant pictures and testimonials, research results, surveys across the years, and partnering/funding strategies provided. Of special interest is the social support dimension of the program. Participants have developed a sophisticated network to support each other outside of the exercise and wellness programs provided by Fit for the Next Fifty.

PERCEIVED EXERTION IN PHYSICAL ACTIVITY MEASUREMENT ACROSS THE LIFECOURSE: RESULTS FROM SWAN

Kelly Ylitalo,¹ Carrie Karvonen-Gutierrez,² Barbara Sternfeld,³ and Kelley Pettee Gabriel,⁴ 1. *Baylor University, Waco, Texas, United States*, 2. *University of*

Michigan, School of Public Health, Ann Arbor, Michigan, United States, 3. Kaiser Permanente, Oakland, California, United States, 4. The University of Alabama at Birmingham, Birmingham, Alabama, United States

Physical activity (PA) guidelines recommend 150 minutes of moderate-intensity or 75 minutes of vigorous-intensity PA, in addition to muscle strengthening activities, each week. Many questionnaires ascertain PA frequency, duration, and intensity to benchmark achievement of PA recommendations. However, most scoring algorithms utilize absolute intensity estimates when exertion may be influenced by age or other sociodemographic or health characteristics. This study compared PA estimates with and without adjustments for perceived exertion and determined if that difference was associated with individual characteristics. Women (n=2,711) from the longitudinal Study of Women's Health Across the Nation who completed ≥ 3 Kaiser Physical Activity Surveys (KPAS) across 8 biennial visits were included (baseline age: 46.4 \pm 2.7 years). KPAS responses were converted to metabolic equivalent of a task (METs) using the Compendium of Physical Activities to estimate absolute and perceived intensity-adjusted MET values. Latent class growth modeling identified subgroups of participants following similar patterns of change in the difference between absolute intensity-based and perceived intensity-adjusted estimates across time. Four major trajectory classes emerged with patterns reflecting: (1) lessening high-intensity exercise (2.2%); (2) increasingly high-intensity exercise (3.1%); (3) consistently moderate-intensity exercise (92.0%); and (4) consistently low-intensity exercise (2.8%). Consistently low-intensity exercisers, for whom absolute intensity-based estimates exceeded perceived intensity-adjusted estimates, were more likely to be Japanese or Chinese (p<0.001) and have lower BMI (p=0.05). However, for most participants, absolute intensity-based estimates approximated perceived intensity-adjusted estimates over time, suggesting that traditional PA scoring techniques may provide sufficient estimates for PA in longitudinal cohort studies of mid-life and older adult women.

PHYSICAL ACTIVITY IMPACTS WALKING DISTANCES AND ENERGY CONSUMPTION OF PATIENTS WITH PERIPHERAL ARTERY DISEASE

Nathaniel Evans,¹ Mahdi Hassan,¹ Danae Dinkel,² Jason Johanning,³ Iraklis Pipinos,³ and Sara Myers,²
1. University of Nebraska Omaha, Omaha, Nebraska, United States, 2. University of Nebraska at Omaha, Omaha, Nebraska, United States, 3. University of Nebraska Medical Center, Omaha, Nebraska, United States

Lower extremity peripheral artery disease (PAD) is attributed to buildup of atherosclerotic plaques preventing adequate blood flow, leading to pain during walking, and ultimately physical inactivity. Normal day-to-day levels of physical activity may impact the distance a subject can walk before claudication pain onset, as well as their energy consumption capabilities. This study compared walking performance (initial claudication distance (ICD) and absolute claudication distance (ACD)), and energy consumption (EC) between active and inactive subjects with PAD. The distinction between groups was made using previous research that declared the average PAD patient walks 3586 steps/day.

Ten subjects were classified as active (\square 3586 average steps/day) and sixteen participants as inactive (<3586 steps/day) based on a 7-day accelerometer measurement. The Gardner progressive treadmill test was used to assess ICD, ACD, and EC. EC was measured using a metabolic cart and calculated from the second minute of walking and the last minute prior to stopping due to claudication pain. The average ICD and ACD for the active group were 130.6 \pm 106.7 meters and 306.0 \pm 184.7 meters, respectively and 143.8 \pm 119.0 meters and 248.0 \pm 156.0 meters, respectively for the inactive group. The average EC for the second minute and last minute were 9.6 \pm 1.9 mlkg⁻¹min⁻¹ and 11.5 \pm 2.4 mlkg⁻¹min⁻¹ respectively for active group and 7.0 \pm 3.1 mlkg⁻¹min⁻¹ and 8.1 \pm 3.8 mlkg⁻¹min⁻¹ respectively for inactive group. The data suggests that the active group had better walking performance and greater energy consumption indicating increased efficiency of oxygen transport and extraction capability in the leg muscles.

PRESCRIBING PERSONALIZED EXERCISE PROGRAMS USING SMARTPHONE SENSORS FOR REMOTE FITNESS ASSESSMENT

Jeremy Jacobs,¹ Ziv Yekutieli,² Mical Arnon,³ Esther Argov,⁴ Keren Tchelet Karlinsky,⁵ Eti Benmoha,³ and Yael Netz,⁶ 1. Hebrew University of Jerusalem, Jerusalem, Yerushalayim, Israel, 2. Montfort, Montfort Brain Monitor, HaMerkaz, Israel, 3. Academic College at Wingate, Academic College at Wingate, HaMerkaz, Israel, 4. Academic College at Wingate, Wingate Academic College, HaMerkaz, Israel, 5. Montfort Brain Monitor, Montfort Brain Monitor, HaMerkaz, Israel, 6. Wingate Academic College, Wingate Academic College, HaMerkaz, Israel

Guidelines for physical activity emphasize multiple fitness components among people aged >65. The age-related increase in variability of fitness components necessitates accurate individualized assessment prior to optimal prescription for personalized exercise program. Accordingly, we tested feasibility and effectiveness of a novel tool designed to remotely assess balance, flexibility, and strength using smartphone sensors (accelerometer/gyroscope), and subsequently remotely deliver personalized exercise programs via smartphone. This pilot study enrolled 52 healthy volunteers (34 females) aged 65+, with normal cognition and low fall-risk. Baseline preliminary data from smartphone fitness assessment were analyzed to generate 42 fitness digital-markers, used to generate personalized exercise programs (5 times/week for 6 weeks). Programs included graded exercises for upper/lower body, flexibility, strength, and balance (dynamic, static, vestibular). Fitness was remotely assessed at baseline and after six weeks. Average age was 74.7 \pm 6.4 years; adherence was 3.6 \pm 1.7 exercise sessions/week. Significant improvement for pre/post testing was observed for 10/12 digital-markers of strength/flexibility for upper/lower body (sit-to-stand repetitions/duration; arm-lift duration; torso-rotation; arm-extension/flexion). Balance improved significantly for 6/10 measures of tandem-stance, with consistent (non-significant) trends observed across 20 balance digital-markers of tandem-walk and one leg-stance. Balance showed greatest improvement among the 37 participants exercising ≥ 3 /week. These preliminary results serve as proof of concept among people aged >65: high adherence and improved

fitness confirm the potential benefits and niche for remote fitness assessment used to generate personalized exercise programs. Future research is required to confirm the benefits among specific patient groups, such as those with frailty, deconditioning, cognitive and functional impairment.

RELIABILITY OF GRIP STRENGTH AS A PREDICTOR OF HAND LIMITATION AMONG U.S. OLDER ADULTS: HOW GOOD IS GRIP STRENGTH?

Rachel Logue, Susan Brown, Rebecca Hasson, and Matthew Davis, *University of Michigan, Ann Arbor, Michigan, United States*

Grip strength is commonly used to assess hand function in older adults and is associated with health outcomes including muscle strength, cognition, and mortality. However, the degree to which grip strength predicts an actual hand limitation is unknown. This study evaluated grip strength as a predictor of hand limitations associated with activities of daily living. Using the 2011-14 National Health and Nutrition Examination Survey (NHANES), we selected five self-reported hand-related functional limitations to classify older adults reporting one or more limitations versus those with no limitations. We identified 2,064 older adults (age \geq 65), 31% of whom reported a hand-related limitation. Odds ratios were used to assess the association between grip strength quartile and the likelihood of a hand limitation while controlling for sex, race/ethnicity, education level, income, and pain. Receiver operator curves were used to evaluate the degree to which grip strength discriminates between those with limitations versus those without. Older adults with very low grip strength (lowest quartile) were more likely to have at least one limitation (OR:6.1, 95% CI:3.2,11.8) than those with high grip strength (highest quartile). However, receiver operator curves suggested grip strength only modestly discriminated hand limitations (area under curve:0.71). While self-reported hand limitations were associated with lower grip strength, it was a relatively poor predictor of hand impairments among older adults. This study suggests grip strength may not predict hand function as well as previously thought. Better assessments are needed to adequately evaluate upper extremity impairments to help older adults maintain functional independence.

RESISTANCE TRAINING IMPROVES MOBILITY DISABILITY IN COMMUNITY-DWELLING OLDER ADULTS: A META-ANALYSIS

Christina Prevett,¹ Kevin Moncion,² Stuart Phillips,² Julie Richardson,² and Ada Tang,² 1. *McMaster University, Concord, North Carolina, United States*, 2. *McMaster University, McMaster University, Ontario, Canada*

Mobility disability is the impairment in function that affects the performance of daily tasks due to declines in physical function. Exercise interventions, particular resistance training, may have a positive impact on mobility disability, but the evidence for the effects of resistance training in older adults with mobility disability has not been previously systematically reviewed. This study was a systematic review of evidence related to resistance training on physical function for adults over 65 years of age with mobility disability. Four databases (PEDro, MedLine, Ovid, Web of Science) were searched from inception to February 2, 2021 for randomized

controlled trials. Twenty-four articles from 22 studies (3,656 participants) were included in the review. Mean participant age ranged from 63-87 years and exercise interventions ranged from 10 weeks to 12 months in duration. Greater changes in 6-minute Walk Test (6MWT) distance (n=638, $p<0.0001$; mean difference (MD) 16.1 metres; 95%CI 12.3-19.9), lower extremity strength (n=785, $p<0.0001$; standard MD 2.01; 95%CI 1.27-2.75) and usual gait speed (n=2,106, $p<0.001$; MD 0.05 metres/second, 95%CI 0.03-0.07) were seen with resistance training as compared to control. These results were maintained if resistance training was a sole intervention or a component of a multi-component program. Sensitivity analysis based on risk of bias concerns did not change results. This review demonstrates that resistance training improves walking capacity, strength and walking speed in community-dwelling older adults and may facilitate aging in place. Since improvements in strength and gait speed contribute to independence, our results indicate highly beneficial outcomes for older persons.

SEX DIFFERENCES IN POWER DECREMENT IDENTIFIED ACROSS THE LIFESPAN

Anthony Campitelli,¹ Sally Paulson,² Jennifer Vincenzo,³ Jordan Glenn,⁴ Megan Jones,¹ Melissa Powers,⁵ Joshua Gills,¹ and Michelle Gray,¹ 1. *University of Arkansas at Fayetteville, Fayetteville, Arkansas, United States*, 2. *University of Arkansas at Fayetteville, Cincinnati, Ohio, United States*, 3. *University of Arkansas for Medical Science, Fayetteville, Arkansas, United States*, 4. *Neurotrack Technologies, Redwood City, California, United States*, 5. *University of Central Oklahoma, Edmond, Oklahoma, United States*

Muscular power has been shown to be a significant predictor of physical function in older adults, but assessments of power have traditionally been performed in movements not specific to activities of daily living (ADLs). Recent research examined power in the context of ADL-specific movements, but it is unclear how ADL-specific lower-body power differs over lifespan in males and females. This investigation sought to describe ADL-specific power decline across the lifespan and analyze differences between the sexes. Adults (n = 557) aged 18-89 volunteered and were divided into age cohorts (18-30, 50-59, 60-69, 70-79, and 80-89 years). Participants performed a sit-to-stand (STS) task with as much velocity as possible while connected to a linear position transducer (LPT). The LPT calculated average and peak power. The average result of 5 individual STS trials was analyzed for each of the power variables. The first significant decrement in average STS power ($p < .01$) was observed at an earlier age cohort in males than females (60-69 in males vs. 70-79 in females). The per decade magnitude of power decrement after age 60 was larger in males than females in both absolute magnitude and percent decrease (11.74 vs. 10.09% decrease per decade). As power and physical function are correlated, this may have implications for the rate and age of functional decline in males. Additionally, understanding the differences in ADL-specific power decline between males and females gives clinicians and health professionals valuable information for developing preventative fitness paradigms specific to members of a given sex.

STIMULATING A MATURE BODY'S DEFENSE SYSTEM BY MAINTAINING PHYSICAL ACTIVITY: A LITERATURE REVIEW

Mary Murphy, *Fairfield University, Fairfield, Connecticut, United States*

This review provides summary of research findings on the effects of exercise for changes in the immune system most associated with aging. Immunosenescence is identified as an immune dysregulation with aging that leaves an older adult susceptible to infections and a host of immune-related disorders. Extrinsic modulators of immunosenescence include pathogens, mental stress, nutrition, and exercise. Moderate short acute exercise over time enhances the immune system. Heavy exertion or prolonged exercise bouts may contribute to immunosenescence. In one study, a J-curve result was identified for upper respiratory tract infection. A moderate exercise workload was associated with a 40-50% decrease in upper respiratory tract infections while a 2-6-fold increase was identified among individuals consistently completing heavy exertion. Transient increases of the inflammatory markers of C-reactive protein and Interleukin-6 are noted after excessive exercise. The older adult should consider small increments of change in an exercise load to limit exercise-induced inflammation. These same inflammatory markers are chronically expressed in obese individuals in a resting state. Strategies to manage weight within recommended range to avoid obesity will limit activation of proinflammatory immune cells. In conjunction with physical activity, the lifestyle behaviors that most support immune system health include adequate sleep, nutrition, hydration, and avoidance of excessive alcohol intake. When planning a safe moderate exercise workload, additionally consider hygienic practices to lower transmission of pathogens. Transmission decreases with hand washing, limited hand-to-face contact, distance from large crowds or those with cough, avoiding spaces with poor ventilation and update vaccinations.

TEXTING OLDER SISTERS TO STEP (TOSS) USING FITBITS TO PROMOTE PHYSICAL ACTIVITY: A FEASIBILITY STUDY

Pamela Bowen,¹ William Opoku-Agyeman,² Veronica Mixon,³ Olivia Affuso,¹ and Olivio Clay,⁴

1. *The University of Alabama at Birmingham, Birmingham, Alabama, United States*, 2. *Healthcare Management, University of North Carolina at Wilmington, North Carolina, United States*, 3. *UAB, Birmingham, Alabama, United States*, 4. *University of Alabama at Birmingham, Birmingham, Alabama, United States*

Black women are disproportionately diagnosed with obesity (BMI \geq 30 kg/m²). Obesity is a preventable but complex, public health problem that is multifaceted, chronic, and approximately 58% of Black women 60 years and older are classified as obese, compared to 38% of their White counterparts. This 12 week, pre/post, 2-group study aimed to determine if a peer-informed physical activity (PA) intervention with peer support would be feasible among community-dwelling, obese, older Black women to promote regular PA. Forty-eight potential participants were screened, 24 categorized as obese were enrolled and completed the study. The mean age was 64 (SD 3.0) years. Steps were measured by a Fitbit-Inspire with data successfully collected on 98% of days with the treatment group averaging

a daily increase of 700-steps more than the control. Evaluation of intervention's acceptability revealed that 100% enjoyed the study and using the Fitbit device. Text message readability was 100% and 95% said the study was motivational. Additionally, 8.3% said daily prompts were too frequent, 12% indicated that future studies should include additional social support, and 88% did not comment on the Fitbit community option for support, suggesting that this feature was not practical. Findings demonstrated that this intervention meets the criteria of being scalable, low cost, feasible, and acceptable for the older Black women. Using self-monitoring techniques in combination with at least one other behavioral strategy, such as our TOSS messages (cues for motivation) as the delivery channel for health promotion messages are a promising approach to increase PA behaviors.

THE ASSOCIATION BETWEEN VISION ACUITY, SLEEP DURATION, AND PHYSICAL ACTIVITY AMONG US ADULTS AGED 50 YEARS AND OLDER

Shu Xu, *University of Massachusetts Boston, Dorchester, Massachusetts, United States*

Studies suggested that people with low vision are more likely to have worse sleep quality and less frequent participation in physical activities compare with people with better vision. Studies also showed that physical activities is a very important factor for one's sleep. However, there is relatively little research on the association between vision acuity, sleep, and physical activity. This study examines the relationships between vision acuity and sleep duration among middle-aged and older adults in the US, and the role of leisure-time physical activity in this relationship. Using nationally representative data from the National Health and Nutrition Examination Survey 2007-2008, a cross-sectional analysis on adults age 50 years and older was conducted (n=2,247). Visual acuity was assessed by participant's vision of better-seeing eye (i.e., none, mild, moderate, and severe visual impairment), and we measured sleep duration (i.e., short, average, and long duration) and leisure-time Physical Activity (i.e., inactive/insufficiently active and sufficiently active). Descriptive analysis showed that 31.06% of older adults experienced moderate or severe visual impairment, and 46.81% respondents experienced abnormal sleep duration. Multinomial logistic regression analyses showed that compared to people without visual impairment, people with moderate or severe visual impairment were more likely to have longer sleep duration than normal sleep duration (OR, 1.62, p<0.05). Leisure-time physical activity was not found to significantly mediate the relationship between visual acuity and sleep duration. Other variables were controlled in the models. Findings suggest that US adults age 50+ with low vision are at greater risk of experiencing abnormal sleep duration.

Session 9425 (Poster)

Policy, Financing, and Social Service Delivery

A POLICY MAPPING ANALYSIS OF THE U.S. CONGRESSIONAL APPROACH TO MEDICAL AID-IN-DYING

Nancy Kusmaul,¹ Ji Hyang Cheon,² and Allison Gibson,³ 1. *University of Maryland, Baltimore County, Baltimore,*

Maryland, United States, 2. University of Maryland Baltimore, University of Maryland Baltimore, Maryland, United States, 3. University of Kentucky, University of Kentucky, Kentucky, United States

Oregon was the first state to legalize medical aid-in-dying (MAID), in 1994. Since then eight states and Washington, DC have legalized MAID through legislation. Despite literature exploring the legal and ethical aspects of MAID, very little research examines MAID policy at the federal level. This study aimed to 1) examine the objectives of MAID legislation introduced to the US Congress, and 2) investigate whether these bills increase or decrease access to MAID. This study used the congress.gov website to search for bills related to MAID introduced by the US Congress between 1994 and 2020. From the 98 bills identified, we excluded bills that were not directly related to MAID or were introduced in subsequent congresses. In total, 23 bills were retained and analyzed. The greatest number of bills aimed to restrict funds for MAID, followed by bills that sought to regulate the drugs used for MAID. Other bills prohibited the development of policies supporting MAID, regulated penalties for practitioners related to the drugs used for MAID, and restricted legal assistance for accessing MAID. These bills intended to block or limit patient access to MAID by restricting drugs, funds, health care services, legal assistance, policy, and research. These findings suggest that the federal approach is incongruous with the growing numbers of states that have legalized MAID. Federal policymakers must develop policies to 1) prevent discrimination against vulnerable groups, 2) support funds to study MAID, and 3) build a system to allows eligible individuals to access MAID equally.

ASSISTED LIVING ADMINISTRATORS' VIEWS OF PALLIATIVE CARE

Elise Abken,¹ Molly Perkins,² and Alexis Bender,³

1. University of North Carolina - Chapel Hill, Atlanta, Georgia, United States, 2. Emory University of Medicine, Atlanta, Georgia, United States, 3. Emory University, Atlanta, Georgia, United States

As many older adults with progressive chronic conditions choose to age-in-place in assisted living (AL) communities, external healthcare workers (e.g., those who provide palliative care) increasingly support AL staff in caring for residents with complex health needs. Palliative care is a branch of healthcare dedicated to preserving quality of life by attending to the physical, mental, and spiritual needs of individuals with chronic, life-threatening diseases and is well suited to manage AL residents' progressive medical conditions. However, AL residents and their care partners often face barriers to accessing palliative care. Using data from a larger 5-year NIA-funded study, we examined AL administrator knowledge and use of palliative care in seven AL communities around the Atlanta metropolitan area that were racially, ethnically, and socioeconomically diverse. Findings from thematic analysis of semi-structured interviews with 16 administrators indicated that 15 of 16 administrators were familiar with palliative care. A minority of administrators clearly distinguished palliative care from hospice services and conceptualized it as a "bridge" to hospice services. Administrators emphasized how palliative care assists communities in caring for health concerns in-house rather than

having to send residents to the hospital. Despite their positive view of palliative care, administrators described infrequent use of palliative services in their communities. Findings show that although none of the AL communities integrate palliative care with their service offerings, AL administrators see value in palliative care for their residents. We provide recommendations for improving palliative care access and quality of life for AL residents at end of life.

DO STATE AGENCY ON AGING STRATEGIC PLANS INCLUDE TERMS RELATED TO MALNUTRITION?

Mary Beth Arensberg,¹ Jaime Gahche,² and Johanna Dwyer,³ 1. Abbott, Columbus, Ohio, United States, 2. National Institutes of Health, Bethesda, Maryland, United States, 3. National Institutes of Health, National Institutes of Health, Maryland, United States

Demand for federal nutrition assistance programs is increasing as the older population grows and further accelerated with the COVID-19 pandemic. Older adult nutrition programs are based on federal nutrition guidelines that have traditionally focused on healthy populations, yet many older adults have multiple chronic conditions/advanced age. Some guidelines are changing; the 2020 Dietary Guidelines for Americans recognize older adults' risk for malnutrition and also need for adequate protein to prevent lean muscle loss with age. The 2020 Older Americans Act (OAA) reauthorization included reduction of malnutrition in OAA's official purpose and added program participant screening for malnutrition. The OAA requires State Agencies on Aging submit multiyear strategic plans to receive program funding, but it is unknown how the plans address risks for malnutrition, including overweight, underweight, and muscle loss (sarcopenia/frailty). We searched 51 State Agency on Aging strategic plans posted at advancingstates.org to determine their frequency of mentioning nutrition, malnutrition/underweight/undernutrition, obesity/overweight, frail/frailty, sarcopenia, and dietary supplements/oral nutrition supplements (DS/ONS)/meal replacements. Every state plan included nutrition but less than a third included malnutrition. There was wide variability in how nutrition and malnutrition were incorporated into state goals and strategies. Very few plans included obesity, frailty, and DS/ONS terms; none included sarcopenia. Although there has been some movement, there is need for many State Agencies on Aging plans to address all aspects of malnutrition including overweight, underweight/other factors related to muscle loss (sarcopenia/frailty) that adversely impact healthy aging. Wide disparities in plan structure/use of terms create opportunities for more common approaches/definitions.

DOES CLOSING THE DONUT HOLE REDUCE FINANCIAL BURDENS AMONG MEDICARE PART D BENEFICIARIES?

Yalu Zhang, Lan Liu, Jingjing Sun, Xinhui Zhang, Jiling Sun, Xinming Song, and Gong Chen, Peking University, Beijing, Beijing, China (People's Republic)

The Medicare Part D donut hole has been gradually closed since 2010. But it is still unclear how it has impacted the beneficiaries' relative financial burdens, especially in the later stage of the closing plan. The measurement of catastrophic health expenditure induced by prescription drugs (CHE-Rx)

reflects the relative financial burdens to beneficiaries' household income, which bears more information than the measure of dollar-value expenses or the absolute poverty line used in prior studies. Using the Medical Expenditure Panel Survey 2008-2017 longitudinal national representative data and the method of difference-in-differences, this study found that the donut hole closing policy was associated with more usage of prescription drugs ($b=2.84$, $p=0.023$) and a higher likelihood of experiencing CHE-Rx ($b=2.4\%$, $p=0.011$) among those who fell in the donut holes. Besides, the results show that the donut hole closing policy did not generate any immediate effects on prescription drug usage, CHE, and CHE-Rx. For the first time, this paper examined both the aggregated and marginal impact of the policy implementation, which had closed by an additional 35% between 2013 and 2017, on the relative financial burden among the beneficiaries.

HOME- AND COMMUNITY-BASED SERVICES USE PATTERNS AND FUNCTIONAL IMPROVEMENT AMONG OLDER CARE RECIPIENTS IN TAIWAN

Hsiao-Wei Yu,¹ Shih-Cyuan Wu,² and Ya-Mei Chen,² 1. *Chang Gung University of Science and Technology, Taoyuan City, Taoyuan, Taiwan (Republic of China)*, 2. *National Taiwan University, Taipei, Taipei, Taiwan (Republic of China)*

The new version of Taiwan's 10-Year Long-Term Care Plan launched in 2016 aims to reinforce the integration of home- and community-based services (HCBS). The underlying HCBS use patterns and effectiveness of functional improvement among care recipients merit investigation. The purpose of the study was to examine the association of HCBS and changes in ADLs among care recipients with different levels of disabilities in Taiwan. We accessed the sub data of Taiwan's Long-Term Care Services Management Online System. Samples were aged 65 and over and had completed records of baseline and reassessment information during 2018 ($N = 4787$). Latent class analysis and multivariate linear regression were applied to examine the relationship of HCBS and functional changes. Four HCBS subpatterns were found: home-based personal care services (home-based PS) (59.16%), home-based reablement services (home-based RS) (23.90%), home-based multiple services (home-based MS) (11.93 %), and community-based services (5.01%). In the cases with mild disabilities at baseline, recipients receiving home-based RS had higher probabilities of improving in ADLs among four HCBS subgroups (for example: $\beta = 2.65$, $SE = 1.19$ in comparison to home-based PS). Care recipients with moderate-to-severe disability at baseline, ADLs improvement was only found in home-based PS ($\beta = 1.63$, $SE = 0.82$ in comparison of home-based MS). In the cases with profound disabilities, home-based PS showed positive effects on ADLs improvement ($\beta = 2.45$, $SE = 0.80$ in ADLs, compared to home-based RS). The study suggested that HCBS subpatterns had different impacts on older adults with different disability levels.

LEADERSHIP AMONG DIRECTOR OF SOCIAL WORK AT SKILLED NURSING FACILITIES (SNFS)

John Paul Abenojar, *Walden University, Arlington, Virginia, United States*

Skilled Nursing Facilities (SNFs) provide ongoing care to the seniors and chronically ill. To maximize the quality of

this care, SNF staff must be trained to respond to patient care crises and communicate across departments. Although researchers have studied the leadership styles, strategies, and interactions of facility administrators and nursing directors, little was known about the leadership styles and strategies employed by the director of social worker (DSW). The aim of this phenomenological study was to explore how DSW influenced leadership policies, prepared subordinated for crisis intervention and management, perceived that social workers influenced patient care decisions, and believed that communication amongst SNF staff about patient care could be improved. The conceptual framework was based on the multilevel leadership model construct, the situational leadership model construct, and the complex adaptive leadership model construct. Participants included a purposive sample of 10 DSW working in a large, corporate SNFs in Virginia. Data were collected via in person, semi structured interviews consisting of open-ended questions. Data were analyzed via Hycner's phenomenological approach. Findings from this investigation helped clarify roles and responsibilities of DSW, thereby improving the leadership they provide to subordinate social workers. Findings may be used to improved communication across professionals within SNFs and in their role in patient decisions.

LEADERSHIP AMONG DIRECTORS OF SOCIAL WORK IN LONG TERM CARE FACILITIES

John Paul Abenojar, *Walden University, Arlington, Virginia, United States*

Long term care facilities (LTC) provide ongoing care for seniors and chronically ill. To maximize the quality of the care, LTC staff must be properly trained to respond to patient care crises and communicate across departments. Although researchers have studied the leadership styles, strategies and interactions of facility administrators and nursing directors there is a substantial gap in the literature on the leadership styles and strategies employed by Directors of Social Work (DSW). The aim of this phenomenological study was to address this gap in research by exploring how DSW influenced leadership policies, prepared subordinates for crisis intervention and management, perceived that social workers influence decision making in patient care, and believed that communication amongst LTC staff about patient care could be improved.

PREPARING EFFECTIVE INTERPROFESSIONAL TEAMS TO MEET THE NEEDS OF OLDER ADULTS IN INTEGRATED HEALTHCARE SETTINGS

Karen Bullock,¹ Kim Stansbury,¹ David Fitzpatrick,² and Gloria Anderson,¹ 1. *North Carolina State University, Raleigh, North Carolina, United States*, 2. *NCSU, RALEIGH, North Carolina, United States*

Background: Gerontology education has evolved from focusing primarily on the individual practitioner outcomes to promoting integrated, inter-professional team approaches to integrated care. Practicum training and service learning are effective pedagogy for paraprofessionals in integrated care settings to support clinicians and advance their effectiveness in meeting the needs of older adults. Interprofessional education (IPE) aims to enhance the capacity of practitioners to work collaboratively as integrated team members. Yet, little is

known about the implementation of IPE in colleges and universities that are not affiliated with a medical center or medical school. This presentation will describe the implementation of IPE in a School of Social Work without a medical school system. We will explore students' experiences with the implementation, facilitation, and evaluation of this workforce development model, and will discuss both challenges and successes. Methods: Narrative data collected over the past two-year period with social work student participants in IPE reflect their perspectives on the selection process for the specialized training, placement in an interprofessional integrated care setting, and the learning experience. Participants represented cohorts of more than 200 trainees. Results: Challenges of effective interprofessional health care teams include the approach taken to integrating the teams, level of knowledge and skills required to be an effective team member, and the need for supervision within integrated care experiences. Successes include increased professional self-efficacy. Participants reported post-completion of IPE, (1) desirable outcomes achieved for their patients, such as care satisfaction and role satisfaction for themselves as practitioners.

THE MEDICARE CURRENT BENEFICIARY SURVEY (MCBS): PROVIDING UNIQUE ACCESS TO DATA ON THE MEDICARE POPULATION

Hildie Cohen,¹ Sarah Hoyt,² Sara Navin,³ Jennifer Titus,³ and Mia Ibrahim,⁴ 1. NORC at the University of Chicago, Phoenix, Arizona, United States, 2. NORC at the University of Chicago, Bethesda, Maryland, United States, 3. NORC at the University of Chicago, Chicago, Illinois, United States, 4. NORC at the University of Chicago., Bethesda, Maryland, United States

The Medicare Current Beneficiary Survey (MCBS) is a continuous, multipurpose survey of a nationally representative sample of the Medicare population, conducted by the Centers for Medicare & Medicaid Services (CMS). It collects data on demographics, health insurance, health status, health care expenditures, satisfaction with care, and access to care for Medicare beneficiaries. The MCBS provides a unique source of information regarding beneficiaries aged 65 and over and beneficiaries aged 64 and below with disabilities residing in the United States that cannot be obtained solely through CMS administrative sources. For researchers interested in issues of health care utilization and cost, CMS releases two Limited Data Set (LDS) files for each data year and a Public Use File (PUF) freely available for download and use. Also, special topic based PUFs have been released on the impact of COVID-19 on Medicare beneficiaries. This presentation will demonstrate the importance of the MCBS for research on the Medicare population, discuss how researchers can access the data, where researchers can find published MCBS estimates, what content areas have recently been added, such as food insecurity, limited English proficiency, and COVID-19 vaccination uptake and what new content is on the horizon. The presentation will also discuss the operational challenges posed by the COVID-19 pandemic, and the content enhancement opportunities created by the public health emergency. It will conclude with a review of the suite of materials and documentation available for data users to enhance their research and utilize more timely data.

Session 9430 (Poster)

Psychological Well-Being and Successful Aging

AGE DIFFERENCES IN EXPERIENCING MEANING IN LIFE: A MULTIDIMENSIONAL APPROACH

Nicole Long Ki Fung,¹ and Helene Fung,² 1. *The Chinese University of Hong Kong, Hong Kong, Hong Kong*, 2. *The Chinese University of Hong Kong, Shatin, N.T., Hong Kong, Hong Kong*

Coherence, purpose and significance were defined as the three facets of the presence of meaning in life (Martela & Steger, 2016). This study investigated the age differences in the three facets of meaning in life between younger and older adults. We recruited 241 younger adults (Mean=18.72, SD=1.50, 36.5% male) and 114 older adults (Mean=64.93, SD= 5.94, 52.6% male) from Hong Kong to fill out a one-hour online survey. We adapted the Multidimensional Existential Meaning Scale, which measured sense of coherence, purpose, significance. In specific, the adapted version measured significance in two sub facets: the naturalistic significance (important to other people) and cosmic significance (impact lasts beyond lifetime and space). The results showed that older adults had higher sense of coherence ($t=3.47$, $p<.001$), higher sense of cosmic significance ($t=6.29$, $p<.001$) but lower sense of purpose than younger adults ($t=-2.02$, $p<.05$). There were no significant differences in naturalistic significance between the two age groups ($t=1.24$, $p=.22$). Within both age groups, participants had the highest score in purpose, followed by coherence and naturalistic significance. They had the lowest score in cosmic significance. This study illustrated that younger and older adults have different absolute levels of meaning facets but are similar in the relative levels of meaning facets. Further studies can investigate how changes in absolute levels of meaning facet and preservation of the relative levels may affect well-being across age.

CORRELATES OF PSYCHOLOGICAL WELL-BEING AMONG KOREAN VIETNAM WAR VETERANS

Hyunyup Lee,¹ Sungrok Kang,¹ Soyoung Choun,² and Carolyn Aldwin,² 1. *Korea Military Academy, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Oregon State University, Corvallis, Oregon, United States*

Prior research on Veterans' mental health has largely focused on identifying risk and protective factors for negative psychological symptoms such as PTSD. However, mental health indicates not merely absence of psychopathology, but also the existence of positive psychological well-being (Keyes, 2005). Thus, the current study aimed to examine the correlates of psychological well-being, which is less studied, in an Asian sample, Korean veterans. Data for this 2017 study were from Korean Vietnam War Veterans Study. Participants were 348 male veterans, and their mean age was about 72 years old (SD = 2.7, range = 65-84). Using Keyes' (2002) classification criteria, psychological well-being was divided into three types: flourishing (9.5%), moderately health (59.95%), and languishing (25.3%). Own-way analyses of variance showed that the groups did not differ in demographic variables (age, marital status, education, and

income). Further, there were no differences in combat exposure, negative appraisals of military service, smoking, and alcohol consumption. However, significant group differences were found for resources; Scheffé's post-hoc analyses indicated that optimism, positive appraisals of military service, four types of social support (family, significant others, friend, and military peer), and self-rated health were significantly different among the groups, and highest in the flourishing group. The moderately health group showed higher levels of positive appraisals of military service and four types of social support than the languishing group. Thus, the majority (about 60%) of Korean Vietnam veterans were moderately psychologically healthy in this sample, but those with positive psychosocial resources were more likely to be healthiest.

DAILY ACTIVITY ENGAGEMENT PREDICTS MORE POSITIVE AFFECT ESPECIALLY ON DAYS WHEN A PERSON FEELS YOUNG

Erica O'Brien,¹ and Shevaun Neupert,² 1. *Pennsylvania State University, University Park, Pennsylvania, United States*, 2. *North Carolina State University, Raleigh, North Carolina, United States*

Engagement in a wide array of mental, social, and physical leisure activities confers several health benefits. Indeed, theories of successful aging argue that an active lifestyle serves as an important criterion for maintaining high levels of psychological, functional, and physical well-being in old age. Findings from parallel studies also show that people who hold positive (self-)views of aging exhibit higher and maintained levels of well-being over time. Yet, whether views of aging enhances the link between activity engagement and well-being - and whether they do so on a daily basis - remains unknown. This study therefore sought to extend prior literature by examining the relationship between activity engagement, subjective age, and affective ratings within-person over several days. Old adults (N = 115; Age: Range = 60 - 90, M = 64.65, SD = 4.86) in the Mindfulness and Anticipatory Coping Every Day (MACED) study completed an 8-day daily diary. Participants reported on their positive and negative affect, the age they subjectively felt compared to their actual age, and the number and types of leisure activities in which they engaged. Results from multilevel analyses indicate that people felt more positive on days when they also engaged in more activities (total across mental, social, physical types) than usual. Moreover, the effect of activity engagement was most pronounced on days when people felt younger than usual. No effects were found for negative affect. Preliminary findings suggest that people benefit psychologically from daily leisure activities and a positive self-view of aging.

OLDER PORTUGUESE AND MEXICAN ADULTS AND SEXUAL WELL-BEING? A CROSS-CULTURAL QUALITATIVE STUDY

Sofia von Humboldt,¹ Neyda Ma. Mendoza-Ruvalcaba,² José Alberto Ribeiro-Gonçalves,¹ Gail Low,³ and Isabel Leal,¹ 1. *Instituto Superior de Psicologia Aplicada (ISPA), Lisboa, Portugal*, 2. *Universidad de Guadalajara CUTONALA, Guadalajara, Jalisco, Mexico*, 3. *University of Alberta, Edmonton, Alberta, Canada*

Objectives: Sexual well-being (SWB) refers to the subjective emotional and cognitive evaluation of the quality of

the individual's sexuality, it plays a relevant role in quality of life and health promotion on old age and has cross-cultural implications. The aim of this study is to analyse comparatively the perspectives of older adults on their SWB in Portugal and Mexico. Methods: Data were collected from 86 Portuguese and 80 Mexican community-dwelling participants aged 65 years and older, using a semi-structured interview protocol. Older adults were inquired about their perceptions on what contributes to their sexual well-being. Socio-demographic data were also enquired. Content analysis was used to identify key themes. Results: Outcomes indicated eight themes: eroticism, supportive relationship, positive self-concept, health and self-care, romance, active life, tenderness and care, and no pain and no pregnancy restrictions, for both samples. Eroticism was the most frequent theme reported by Portuguese participants (31.4%) and health and self-care were the most frequent theme reported by Mexican participants (26.5%). Conclusions: The empirical results of this study indicated that SWB is strongly influenced by socio-cultural and psychosocial values. This cross-cultural comparison between Portugal and Mexico contributes to understand this concept in old age with different perspectives and place a scenario for future culture-adapted interventions and comprehensive policies. Keywords: Mexican, older adults; Portuguese; qualitative study; sexual well-being

PROACTIVE COPING AND MINDFULNESS ARE ASSOCIATED WITH LESS STRESS IN OLDER ADULTS

Lyndsey Graham, and Shevaun Neupert, *North Carolina State University, Raleigh, North Carolina, United States*

We examined the consequences of both chronic and life-event stressors for older adults, as well as antecedent strategies, such as proactive coping and mindfulness, that may mitigate stress. Given the potential negative outcomes associated with stress in older adulthood, exploring strategies to reduce or mitigate the negative impact of stress may be useful in promoting well-being in adulthood. Proactive coping involves an accumulation of resources that leads to reduced or avoided stressors in the future (Aspinwall & Taylor, 1997). Mindfulness calls an individual's attention to the present moment, or may be characterized as an open, accepting attitude (Brown & Ryan, 2003). Using data from the Mindfulness and Anticipatory Coping Everyday study (English et al., 2019; Neupert & Bellintier, 2017), 296 older adults in the United States, aged 60-90 years (M = 64.67, SD = 4.36), participated in relevant online survey measures. Results from multiple regression analyses suggested that people high in both chronic stress and life event stress had worse health, and that people high in proactive coping and mindfulness reported less stress. Study results underscore the impact of stress on health outcomes, and provide support for the use of antecedent strategies to address negative impacts of stress.

RECALLING MEMORIES OF LIFE'S CHALLENGES WITH PURPOSE AND REDEMPTION: RESOURCES TO FOSTER RESILIENCE?

Shubam Sharma,¹ Joshua Perlin,² and Susan Bluck,³ 1. *Kennesaw State University, Kennesaw, Georgia, United States*, 2. *University of Florida, Gainesville, Florida, United States*, 3. *University of Florida, University of Florida, Florida, United States*

Unique life challenges occur across life phases, including later life. Life story research suggests that the way challenges are narrated has consequences for multiple domains of well-being. Two factors for positively reframing challenges are one's sense of purpose in life (Windsor et al., 2015) and redemption (McAdams et al., 2001). This study used moderated-mediation analyses to investigate whether: 1) challenge relates to psychosocial and cognitive well-being, differentially by age, and 2) narrating with greater purpose and redemption ameliorates effects of challenges on well-being, by age. Participants (N = 99 young, 88 older adults) rated self-disruption of challenging events from their lives (IV1) and reported number of recent life challenges experienced (IV2). Eudaimonic well-being (DV1) and cognitive well-being (DV2) were assessed. Purpose (M1) and redemption (M2) were reliably content-analyzed from participants' narratives of autobiographical challenges (e.g., illness, loss of other). For Aim 1, young and older adults who experienced more challenges showed lower eudaimonic well-being but higher cognitive well-being. Perceived self-disruption was unrelated to well-being. For Aim 2, results showed that how individuals narrate (i.e., with purpose, with redemption) the challenges that have occurred in their lives mediates effects of challenge. Specifically, exhibiting a sense of purpose mediated the relation between perceived self-disruption and cognitive well-being. Redemption buffered negative effects of both self-disruption and number of challenges on eudaimonic well-being. Mediation results held regardless of age. Findings suggest purpose and redemption are two narrative mechanisms that act as psychological resources to support well-being in the face of life's inevitable challenges.

RESILIENCE AMONG OLDER ADULTS WITH TYPE 2 DIABETES FROM THE LOOK AHEAD TRIAL

KayLoni Olson,¹ Marjorie Howard,² Jeanne Mccaffery,³ Gareth Dutton,⁴ Mark Espeland,⁵ Karen Johnson,⁶ Felicia Simpson,⁷ and Rena Wing,⁸ 1. *Alpert Warren Medical School of Brown University, Providence, Rhode Island, United States*, 2. *Wake Forest University Health Sciences, Winston Salem, North Carolina, United States*, 3. *University of Connecticut, Storrs, Connecticut, United States*, 4. *University of Alabama at Birmingham (UAB), Birmingham, Alabama, United States*, 5. *Wake Forest School of Medicine, Winston-Salem, North Carolina, United States*, 6. *University of Tennessee Health Science Center, Memphis, Tennessee, United States*, 7. *Department of Mathematics, Winston-Salem State University, Winston-Salem, North Carolina, United States*, 8. *The Miriam Hospital, Providence, Rhode Island, United States*

There is growing interest in identifying factors protecting against aging-related decline. This cross-sectional study evaluated associations of self-reported resilience (ability to bounce back) with factors linked to aging-related decline among older adults with Type 2 diabetes (T2DM). Participants were 3,199 adults (72.2±6.2 years, 61% female, 61% white, BMI 34.2±8.2 kg/m²) enrolled in Look AHEAD (a multi-site RCT comparing weight loss to diabetes education among individuals with T2DM), who were followed observationally after the 10-year intervention was discontinued. The following items were assessed approximately 14.4yrs post-randomization: Brief Resilience Scale;

overnight hospitalizations in past year; physical functioning measured objectively (gait speed, grip strength) and via self-report (Pepper Assessment Tool for Disability; Physical quality of life (QOL; SF-36)); a composite measure of phenotypic frailty based on having ≥3 of unintentional weight loss, low energy, slow gait, reduced grip strength, physical activity. Depressive symptoms (PHQ-9) and mental QOL (SF-36) were also measured. Logistic/linear regression was used to evaluate the association of these variables with resilience adjusted for age, race, and gender. Greater resilience was associated with lower BMI (p=.01), fewer hospitalizations (p=.02), better physical functioning (i.e., lower self-reported disability, better self-reported physical QOL, faster gait speed, greater grip strength and lower likelihood of meeting criteria for frailty; all p<.001), fewer depressive symptoms and greater mental QOL. Resilience is associated with better performance on indicators of overall functioning and risk for decline among older adults. Findings correspond with efforts to shift narrative on aging beyond 'loss and decline' to highlight opportunities to facilitate healthy aging.

THE EFFECT OF BEHAVIORAL ACTIVATION ON OLDER ADULTS' ENGAGEMENT AND WELLBEING: A RANDOMIZED CONTROL TRIAL PROTOCOL

Julia Turner Scott,¹ Mary Luszcz,² Trevor Mazzucchelli,³ Ruth Walker,² and Tim Windsor,² 1. *Flinders University, Brompton, South Australia, Australia*, 2. *Flinders University, Adelaide, South Australia, Australia*, 3. *Curtin University, Perth, Western Australia, Australia*

Meaningful activity engagement in later life is widely recognized as crucial for ageing well, but age-related changes and transitions can impede such participation. A behavioral activation framework can provide a person-centred, value-consistent therapeutic approach to increasing activity engagement that is both easy to administer, cost effective and accessible to a broad audience. Although there is evidence supporting the utility of behavioral activation as a treatment for depression in older adults, this study will be the first to examine whether a behavioral activation is more effective in increasing activity engagement and psychological wellbeing among a non-clinical sample of older adults, compared to a multi component positive psychology intervention. This randomized controlled trial will examine the impact of two therapeutic approaches on activity engagement and wellbeing among older adults. One hundred and fifty adults aged 65+ who have relatively lower scores on a measure of engagement with life will be randomized to either a behavioral activation-based intervention, or a multi-component positive psychology intervention. The interventions will involve six individual weekly sessions conducted via telephone or video conference. Participants will be assessed pre-, post-intervention, and at three months follow-up. Outcome measures will include activity engagement, positive affect, and psychological wellbeing. Intra-individual variability will also be assessed via micro-longitudinal data in the behavioral activation condition. This study will be the first to provide evidence to the effectiveness of behavioral activation as an intervention to increase activity engagement and wellbeing among older adults, compared to other therapeutic approaches to increase psychological wellbeing.

THE MODERATION ROLE OF ACCULTURATION ON DIETARY PATTERNS AND STRESS AMONG U.S. CHINESE IMMIGRANTS

XinQi Dong,¹ and Qun Le,² 1. *Rutgers University, Rutgers Institute for Health, New Jersey, United States*, 2. *Rutgers University, New Brunswick, New Jersey, United States*

Studies have demonstrated that healthy dietary patterns are related to diminished stress. However, the potential moderation role of acculturation on dietary patterns and stress is unclear among the those whose eating habits are impacted by immigration. The aim of this study is to explore the moderation role of acculturation on dietary patterns and stress among Chinese elder immigrants in the United States. Data were conducted from the PINE Study with 3053 Chinese adults aged over 60 years in the Great Chicago area. Dietary patterns were measured via a 48-items Food-frequency questionnaire with frequency and size weighted. Items were identified into different food groups based on Dietary Guidelines. Acculturation was assessed by a 12-item short-scale among the population. Stress was measured via a 10-item Perceived Stress Scale with cutoff 14 indicating either low or high stress. Multiple logistic regression was used to examine the moderation effects on the associations with demographic characteristics, medical comorbidities, and BMI adjusted. After controlling covariates, one unit increasing in fruit consumption (OR: 0.61 (95%CI: 0.52 -0.72)) or coffee (OR: 0.49 (95%CI: 0.36 - 0.67)) was associated with lower odds of stress. However, after adding acculturation as an interaction term, the negative relationship between fruit or coffee consumption with stress was moderated by a higher level of acculturation (fruit: OR: 1.05 (95%CI: 1.02 - 1.08), coffee: OR: 1.05 (95%CI: 1.01 - 1.09) respectively). The associations between dietary patterns and stress may differentiate based on acculturation level among the elder immigrants. Further longitudinal studies should investigate potential causality.

THE ROLE OF AGE, RELIGION/SPIRITUALITY, AND HUMOR IN THE OPTIMISM OF COMMUNITY-DWELLING OLDER ADULTS

Bonnie Kenaley,¹ Eun hae Kim,² Kimberly McClive-Reed,³ and Zvi Gellis,⁴ 1. *Boise State University, Boise, Idaho, United States*, 2. *Texas State University, San Marcos, Texas, United States*, 3. *University of Pennsylvania, NISKAYUNA, New York, United States*, 4. *University of Pennsylvania, Philadelphia, Pennsylvania, United States*

Current literature reveals that perceived optimism decreases with age (D'Argembeau et al., 2011; Newby-Clark & Ross, 2003). However, replication of these studies is limited. In particular, a lack of investigations exists in examining optimism as individuals transition across older adulthood. Considering the dearth of literature that examines the influence of religion/spirituality and humor on the optimism of older adults, 203 members of Osher Lifelong Learning Institutes, age 65 years and older, from Idaho and California completed pen and paper or electronic surveys. The study used hierarchical multiple regression analysis to examine the impact of age, positive religion/spirituality coping skills, and humor on the optimism of community-dwelling older adults. The participant's gender significantly explained a 19.3% variance in the optimism scores, whereas age did not significantly

contribute to the model (R Change =.000). Positive religious or spiritual coping skills and humor significantly contributed to the variance in optimism scores, explaining a 2.3% and 21.6% variance, respectively. In the final model (F (1, 202, = 13.78, p = .000), all variables except age significantly contributed to the model with humor revealing the highest beta value (beta = .467, p = .000). The findings suggest that optimism is perceived differently by gender but does not change with age. While positive religious coping skills influence optimism, internal or external humor strategies may be more helpful to instill, promote or maintain optimism in older adults. The addition of humor assessment items in wellness evaluations and humor-infused interventions may foster optimism in community-dwelling older adults.

THE ROLE OF LAUGHTER FOR SUCCESSFUL AGING OF ALASKA NATIVE ELDERS

Jordan Lewis, *Memory Keepers Medical Discovery Team/ University of Minnesota Medical School, Duluth campus, Duluth, Minnesota, United States*

During a visit over tea and pilot bread, discussing successful aging and well-being, an Inupiat Elder shared that "It's better to live a happier life, enjoy life all you can." These wise words inspired the theme of this chapter which explores the role of laughter in the resilience and wellbeing of Alaska Native Elders. Based on a decade of research, this chapter introduces the concept of Alaska Native Eldership and provides an overview of the five strands of Alaska Native successful aging that contribute to their ability to remain resilient. Laughter is a universal emotional experience, and Alaska Native Elders have taught us that is has different functions that enable us to be resilient and age successfully. Laughter is woven throughout the strands of successful aging as a key to health and well-being and this chapter discusses the four types of laughter used to protect themselves, including redirecting conversations, practicing humility, taking away the power of stressful topics, as well as sharing happiness and laughter with others. This chapter concludes with reflections on how laughter contributes to our ability to find meaning and purpose in life and strengthening our relationships with family and community so we can remain resilient as we age.

Session 9435 (Poster)

Retirement, Financial Well-Being, and Economics of Aging

BENEFITS OF WISE ORGANIZATIONS ON EMPLOYEES' WELL-BEING: A COMPARISON OF YOUNGER AND OLDER WORKERS

Monika Ardelt, and Bhavna Sharma, *University of Florida, Gainesville, Florida, United States*

Research has shown a positive relation between personal wisdom and well-being, particularly in old age. Yet, it is unknown whether wisdom in the workplace also has a positive impact on workers' well-being. We created a wise organization index for nine organizations based on 74 to 390 average employees' ratings of perceived flexibility at work, work opportunities for training and development, satisfaction with work benefits, absence of time pressure at work, work-life

balance, job fulfillment, and job security. We predicted a stronger relation of wise organization on well-being for older workers ($N=269$; age range 50-74, $M=56.08$, $SD=5.04$) than for younger workers ($N=552$; age range 19-49, $M=35.10$, $SD=8.17$) who can more easily change jobs. Results of multigroup analyses in LISREL 9.30 showed that the wise organization index had significant indirect effects on employees' physical and subjective well-being at the second wave of data collection, mediated by employees' perception of wise (fair and supportive) leadership assessed six months earlier and overall work satisfaction (career as calling, satisfaction with career progress, enthusiasm at work, and great workplace) at Wave 2. Contrary to expectations, the effects were not statistically different between the two age groups. However, physical well-being had a statistically stronger association with subjective well-being among younger rather than older workers, possibly indicating a positive health selection effect in the older age group. It appears that wise organizations encourage wise leadership and enable workers to work longer by contributing to their work-related, physical, and subjective well-being.

CHANGES IN CONSUMPTION EXPENDITURES AMONG BABY-BOOMERS AND YOUNG-OLDS: LATENT TRANSITION ANALYSIS

Si Young Song,¹ Hey Jung Jun,¹ Susanna Joo,² and Do Kyung Yoon,¹ 1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea*

The aim of this study was to examine the longitudinal transition of consumption expenditures among both baby-boomers and young-olds in South Korea. We used data from the 6th (2016) and the 7th (2018) waves of the Korean Longitudinal Study of Ageing (KLoSA). The final sample comprised 1,806 baby-boomers (age range=53-61 in 2016) and 1,483 young-olds (age range=65-74 in 2016). Consumption expenditures were observed with nine types of expenses: food, eating out, public education, private education, housing, health-care, clothing, cultural entertainment, and savings. According to the results from latent transition analysis (LTA), three consumption subgroups were identified among baby-boomers: "non-expenditure for education (NE, 69.7%)" group, "high-public education expenditures (PE, 10.7%)" group, and "high-public and private education expenditures (PPE, 19.6%)" group. For baby-boomers, NE and PE were more likely to remain the same type throughout the two waves, and PPE was most likely to move to NE two years later. Meanwhile, the consumption expenditures of young-olds were divided into "low-saving (LS, 63.7%)" group, "high-saving (HS, 40%)" group, and "education cost-centered (EC, 5.3%)" group. In the case of young-olds, the transition between the groups was unlikely to occur across the two waves which can be interpreted as having fewer life cycle changes than baby-boomers. This study suggests that it is necessary to take into account the difference between the generations when understanding longitudinal transition of consumption expenditures.

FINANCIAL PLANNING FOR RETIREMENT: DEVELOPING AN INTEGRATED MODEL

Dannii Yeung,¹ Alvin Ho,² and Alfred Lam,² 1. *City University of Hong Kong, Hong Kong, Hong Kong*, 2. *City*

University of Hong Kong, City University of Hong Kong, Hong Kong

With higher life expectancy of the aging population, retirees nowadays will spend a prolonged period of time after retirement. Yet, past studies have consistently revealed a lack of retirement savings among working adults, implying an inadequacy to maintain the quality of life in late adulthood. This study therefore aims to identify the factors influencing the working adults' intention to purchase financial products for retirement (such as deferred annuity and voluntary contribution to retirement fund) and develop an integrated model of financial planning for retirement. A total of 598 Hong Kong Chinese working adults from diverse age and income groups completed an online survey on intentions to save and purchase specific financial products for retirement. The results of MANCOVA reveal that compared to older workers, younger workers had lower intentions to save and purchase financial products for their retirement even after controlling for their monthly income [$F(16,1797)=2.24$, $p=.003$, partial $\eta^2=.015$]. An integrated model of financial planning for retirement is proposed by incorporating the concepts of the interdisciplinary psycho-motivation model and Theory of Reasoned Actions ($\chi^2 = 40.42$, $p<.001$, CFI = .99, RMSEA = .07, SRMR = .02). In particular, the positive effects of financial literacy, subjective norms, social support, and future time perspective on intention to save and purchase financial products for retirement have been found to be mediated by retirement goal clarity but not attitudes towards retirement. Future direction on promoting younger and older workers' retirement planning especially in the financial domain will also be discussed in the presentation.

MISMATCH BETWEEN PHYSICAL HEALTH AND JOB DEMANDS AMONG OLDER WORKERS BY FULL RETIREMENT AGE

Theresa Andrasfay, *University of Southern California, Los Angeles, California, United States*

Gradual increases to the Social Security full retirement age (FRA) from 65 to 67 were justified by improvements in the health of the older population and a general shift toward less physically demanding jobs. These two trends have been studied independently, but it is important to consider the agreement of these two factors—job demands and health—to understand whether those expected to work longer to receive full benefits have compatible health and job characteristics to do so. Using data from the 1992-2018 waves of the Health and Retirement Study, I observe 19,383 working individuals with FRA ranging from 65-67 while they are approaching retirement (ages 51-60). I compare the prevalence of person-work mismatch—defined by the co-occurrence of physical health conditions and self-reported physical job demands—by FRA. I find that individuals with an older FRA are less likely to be employed in physically demanding jobs while having arthritis. However, they are more likely to be employed in physically demanding jobs while having pain or fair/poor self-assessed health and are more likely to be employed in jobs requiring frequent stooping, kneeling, or crouching while simultaneously having difficulty with these activities. The co-occurrence of physically demanding work while having multiple mobility limitations has remained stable across the FRA cohorts. These findings indicate that

older workers expected to work longer to receive full benefits have not experienced substantial improvements in the compatibility between their physical health and job demands that would facilitate working longer, and by some measures compatibility has declined.

RACIAL AND ETHNIC DIFFERENCES IN RETIREMENT SATISFACTION AMONG OLDER US ADULTS

Samuel Van Vleet, and Sara McLaughlin, *Miami University, Oxford, Ohio, United States*

Along with population aging, the diversity of the older US population is increasing. Research suggests that racial and ethnic minorities experience disadvantages over the life course that can negatively impact later life. Despite this, little research has examined racial and ethnic differences in satisfaction with retirement. Using data from the 2016 wave of the Health and Retirement Study, we compared retirement satisfaction among Black ($n = 1,068$), Hispanic ($n = 674$), Other ($n=161$), and White ($n = 4,833$) older adults (age 65+). Retirement satisfaction was measured with the following item: "All in all, would you say that your retirement has turned out to be very satisfying, moderately satisfying, or not at all satisfying?" Responses were categorized as very satisfied vs. all others. Approximately 43% of Black, 35% of Hispanic, 39% of Other, and 56% of White Americans reported being very satisfied with retirement ($\chi^2(2.4)=58.9$; $p < .0001$). In multivariate logistic models controlling for age, educational level, gender, household income, marital status, and functional limitations, the odds of being very satisfied with retirement were 32% lower for Hispanic (OR=0.68; 95% CI= 0.55, 0.85) and 37% lower for Other Americans (OR=0.63; 95% CI= 0.43,0.92) relative to their White counterparts. No significant difference was evident for Black and White Americans in adjusted analysis (OR=0.96; 95% CI=0.76,1.20). Our findings indicate that inequalities in the retirement experience exist by race and ethnicity in the United States. More research is needed to understand the factors responsible for lower retirement satisfaction among Hispanic and Other Americans.

RETIREMENT, HAPPINESS, AND HEALTH IN JAPAN

Shohei Okamoto, and Erika Kobayashi, *Tokyo Metropolitan Institute of Gerontology, Itabashi-ku, Tokyo, Japan*

While health effects of retirement have been well studied so far, previous findings remain inconclusive, and mechanisms underlying the linkage between retirement and health are unclear. This can be driven by regional or cohort heterogeneity as well as methodological differences, such as outcome measures and identification strategies; thus, much evidence needs to be accumulated. Utilising a national household survey conducted every year in 2004-2019 in Japan (the Japan Household Panel Survey), we evaluate the effects of retirement among Japanese adults aged 50-75 on their happiness and health in addition to other outcomes that could attribute to happiness or health changes (e.g. health behaviours, time use for some activities, and the expenses by item). As outcomes are not measured every year, we analyse 4,340-7,902 person-year observations by 756-1,389 individuals with the necessary information from 2009. To deal with the potential endogeneity of retirement, we adopt an instrumental variable

approach utilising changes in retirement policy and public pension eligible age. Consequently, instruments seem valid only for men, and we find that retirement increases male retirees' happiness and decreases psychological stress while effects on other health measures are not observed. Although their satisfaction with their income decline, perhaps because of the loss of their wage income, they tend to increase the proportion of expenses for cultural and recreational activities. Enhancement in personal life quality by more leisure activities and stress reduction from work, rather than improvements in health behaviours and physical health, may be key to understanding health benefits in retirement.

SOCIOECONOMIC STATUS, TIME SCARCITY AND WELL-BEING IN RETIREMENT

Boroka Bo, *University of California, Berkeley, Berkeley, California, United States*

We tend to think of retirement as a great equalizer when it comes to relief from the pernicious time scarcity characterizing the lives of many individuals in the labor force. Puzzlingly, this is not entirely the case. Using data from the MTUS (N=15,390) in combination with long-term participant observation (980 hours) and in-depth interviews (N=53), I show that socioeconomic characteristics are important determinants of retiree time scarcity. Neighborhood disadvantage gets under the skin via time exchanges that are forged by both neighborhood and peer network characteristics. The SES-based 'time projects of surviving and thriving' undergirding the experience of time scarcity lead to divergent strategies of action and differing consequences for well-being. For the advantaged, the experience of time scarcity is protective for well-being in later life, as it emerges from the 'work of thriving' and managing a relative abundance of choices. For the disadvantaged, the later life experience of time scarcity is shaped by cumulative inequality, further exacerbating inequalities in well-being. The final section of the article offers an analysis and interpretation of these results, putting retiree time scarcity in conversation with the broader literature on socioeconomic status and well-being.

THE ASSOCIATION BETWEEN SUBJECTIVE AND OBJECTIVE FINANCIAL KNOWLEDGE: PATH ANALYSIS TO INVESTOR BEHAVIOR BY AGE

Rain Lee,¹ Jin Sil,² and Euijin Jung,³ *1. Yeshiva University, New York, New York, United States, 2. UC San Diego, San Diego, California, United States, 3. University of Kansas, Kansas, Kansas, United States*

Financial literacy affects stock market participation, as well as individuals' age, gender, income, and education level. However, measuring financial literacy is more appropriate to identify individuals with strong knowledge of finance rather than average individuals with general knowledge. This could be problematic to identify general participation of the stock market and investment as more individuals are now participating without having to have such knowledge. This study explored how individuals' subjective financial skills and well-being affect investment participation by age. Overall, males are likely to participate more in both retirement and non-retirement investment. In between the boomer generation and younger group, the younger generation who reported participating in a non-retirement investment, such

as stock market were having a higher score on subjective financial well-being (STDYX = .052, 95% CI [.07, .08]; $p < .05$). Importantly, among the older group, subjective financial skill score becomes a predictor of participating stock market (STDYX = .09, 95% CI [.01, .17]; $p < .05$). As the result suggest, while younger participants focus more on financial well-being, such as having security on finances, when they are participating in a non-retirement investment, whereas older adults are likely to invest based on their beliefs on financial skills regardless of secured finances. A retirement plan has shifted toward less on savings and more on investing. Older adults are now interested more in participating in investments, such as the stock market than the young population, and the proper preparedness for those older adults in participating in the investment is needed.

THE SOCIAL RELATIONS AND ECONOMIC PREPARATION FOR RETIREMENT OF ONE-PERSON HOUSEHOLDS

Heayoung Sung, *National Pension Research Institute, Jeon-Ju si, Jeollabuk-do, Cholla-bukto, Republic of Korea*

Objectives: The purpose of this study is to find out the effect of middle-aged one-person households on social relations and economic preparation for retirement. In addition, even within one-person households, I attempted to determine the difference according to whether the cause of the households' composition was separation after marriage or a one-person household without a spouse due to being unmarried, bereavement, or divorce. **Methods:** As a result of the analysis using the data of the 2019 Korean Social Survey of the National Statistical Office, single-person households had weaker economic conditions, social relations, and economic preparation for retirement when compared to multi-person households. One-person households lacked a social network to receive help when they face difficulties compared to multi-person households, but there was no effect on group activities or the satisfaction with human relationships. However, households with no spouse had a negative impact on the social network, group activities, and the satisfaction with human relationships. **Conclusions:** Middle-aged one-person households and one-person households with no spouse had a negative effect on economic preparation for retirement, when labor activity and asset variables were not considered. However, statistical significance was not found when these variables were considered.

WHAT ARE WE WORRIED ABOUT? MID-LIFE COUPLES' FINANCIAL CONCERNS ABOUT THEIR RETIREMENT

Jeremy Yorgason,¹ Dikla Segel-Karpas,² Ashley Ermer,³ Hailey Weller,⁴ Shenan Owens,⁵ and Brandan Wheeler,⁶ 1. *Brigham Young University, Provo, Utah, United States*, 2. *University of Haifa, Haifa, Hefa, Israel*, 3. *Montclair State University, Montclair, New Jersey, United States*, 4. *Brigham Young University--Provo, Provo, Utah, United States*, 5. *Brigham Young University, Brigham Young University - Provo, Utah, United States*, 6. *Mississippi State University, Mississippi State, Mississippi, United States*

Retirement is an expected stage of life that couples plan for far in advance. Despite knowing that years of life without regular income are anticipated, some underprepare, leading

to financial uncertainty in later years. In this study we explore financial concerns for retirement expressed by a sample of 335 midlife (Mage=44) couples that participated in the Flourishing Families study. We also examined predictors of those concerns across a 1-year period. Results suggested that both husbands and wives worried about insufficient income, excess spending, and heavy debt in retirement. Minor concerns included being worried about paying for their children's education, net worth, and general expenses. Lower income was predictive of both husbands and wives being worried about having insufficient income in retirement. Higher income was predictive of husbands having concerns about excess spending. Although having retirement benefits was not predictive of any worries, having retirement savings was associated with wives having a greater likelihood of reporting worries about heavy debt and net worth in retirement. Better financial communication was associated with fewer husbands reporting concerns about excess spending and fewer wives reporting concerns about heavy debt. Having concerns about a spouse not being financially responsible were associated with more husbands reporting worries about excess spending and heavy debt in retirement. When wives reported higher social connection with a child, they also were more likely to report worries about expenses. Findings suggest that saving for retirement, communicating well about finances, and being financially responsible are associated with fewer financial concerns in retirement.

Session 9440 (Poster)

Sleep

DAILY EVENING ELECTRONIC MEDIA USE AND SLEEP IN LATER LIFE

Yijung Kim, Shiyang Zhang, and Karen Fingerma, *The University of Texas at Austin, Austin, Texas, United States*

Sleep complaints and disorders are one of the most common disturbances to health and well-being in later life. Evening electronic media use has been shown to influence the subsequent quantity and quality of sleep, but most research focused on younger age groups who are more likely to use new media (e.g., social media) to replace or complement traditional mass media such as television. To investigate how different types of evening media use is related to sleep in later life, we used ecological momentary assessment data from the Daily Experiences and Well-being Study (N = 231; Mage = 73.61) to examine how evening computer use and television viewing affect subsequent sleep hours and perceived sleep quality. Across all evening assessments, 43% of the evenings were spent using computers, and 80% of the evenings were spent watching television. Findings from a series of within-between random effects models indicated that evening computer use and television viewing had independent associations with sleep quantity and quality. That is, older adults reported fewer hours of sleep, more difficulty falling asleep, and worse overall sleep quality on nights following the evening computer use. In contrast, evening television viewing was associated with feeling less tired the next day morning. The results highlight the continued presence of television viewing in older adults' daily lives and their

distinction from general computer use. The social context in which older adults watch television in the evening may potentially explain how different electronic media use influences sleep in later life.

MAKING THE MOST OF ADVERSITY: A FULLY REMOTE ECOLOGICAL MOMENTARY ASSESSMENT AND ACTIGRAPHY STUDY OF HOSPITAL NURSES

Taylor Vigoureux, Christina Mu, and Soomi Lee,
University of South Florida, Tampa, Florida, United States

The COVID-19 pandemic has created challenges and opportunities for research. This is especially true for research on essential workers, such as hospital nurses. In adaptation to the pandemic, the current study aimed to assess the feasibility and acceptability of a fully remote study to collect data on psychological and behavioral measures such as daily stress and sleep, utilizing ecological momentary assessments (EMA) and sleep actigraphy. Our remote study protocol was conducted through a web platform that provided detailed video and written instructions regarding the study and facilitated virtual onboarding meetings with participants. Outpatient day shift nurses (n=86) responded to a background survey, 84 of whom completed 14 days of EMA and sleep actigraphy. Feasibility was assessed by compliance rates to the 14-day study protocol. Acceptability was assessed by analyzing qualitative feedback provided during onboarding meetings (n=82). The compliance rates of EMA (91.8%) and actigraphy (97.9%) were high. The EMA compliance was higher than that from a pre-COVID, non-remote study of inpatient day shift nurses from the same hospital (86.6%, $p=.030$). Themes from content analysis were mostly positive with 51.2% reporting “easy, clear, simple onboarding process” and 16.3% reporting “helpful website”. Only six participants provided solely negative feedback (e.g., “communication problems” or “technical difficulties/preferences”). Our remote study protocol was feasible and well-accepted by nurses. A similar methodology could be used in studies on broader healthcare workers and those caring for aging populations to better understand their unique challenges and develop effective strategies to help them, both during and after the pandemic.

POOR SLEEP MODERATES THE ASSOCIATION BETWEEN GENERALIZED ANXIETY AND HIPPOCAMPAL VOLUME AMONG OLDER ADULTS

Desiree Bygrave,¹ and Regina Wright,² 1. *Benedict College, Benedict College, South Carolina, United States*, 2. *University of Delaware, University of Delaware, Delaware, United States*

Poor sleep is common among older adults, and associated with hippocampal atrophy -- a strong predictor of memory decrements. Underlying this association are psychosocial risk factors, such as generalized anxiety, that may further exacerbate poor sleep and brain pathology. Given that poor sleep and generalized anxiety are often comorbid, there is a critical need to establish whether generalized anxiety is related to hippocampal volume among poor sleepers. To address this gap, this cross-sectional study examined the relationship between generalized anxiety (GAD-7), and total hippocampal volume, and whether it varied as a function of sleep quality (PSQI Total < 5 good sleepers; PSQI Total \geq 5

poor sleepers). Data were analyzed from 165 older adults (mean age = 68.48y, 33% male, 41% African American), free of major disease. Linear regression analysis, adjusting for sex, race, education and depression, showed a statistically significant Generalized Anxiety x Sleep interaction for hippocampal volume ($p=.02$). Further probing of this interaction revealed that among poor sleepers, greater generalized anxiety was associated with lesser hippocampal volume ($p=.01$). Findings suggest generalized anxiety may influence hippocampal volume in the context of poor sleep among older adults. As poor sleep is associated with age-related neurodegeneration, our findings suggest that improvements in sleep quality may reduce the impact of generalized anxiety on hippocampal volume in older adulthood. Future research should examine whether generalized anxiety mediates relations of sleep quality to specific memory outcomes.

RURAL/URBAN DIFFERENCES IN SLEEP DISORDERS AMONG OLDER ADULTS IN GHANA

Abolade Oladimeji, *case western reserve university, cleveland, Ohio, United States*

Sleep plays a significant role in the maintenance of the body, and experiences of sleep disorders may have adverse health outcomes on older adults. While a substantial number of studies have documented rural and urban differences in sleep quality and duration, none has examined rural/urban differences in sleep disorders among older adults in Ghana. The analytical sample included 2,142 older adults (65 years and above) who are part of the cross-national study of the Research on Early Life and Aging Trends and Effects (RELATE) conducted in Ghana in 2007 (μ age = 74, female 54%). The analysis was based on multivariate logistic regression in predicting the odds of experiencing sleep difficulty among older adults and how this may differ based on rural/urban residence. Results reveal that net of other factors, older adults in rural Ghana are more likely to experience sleep disorders than their urban counterparts (OR=1.29, $P<.05$). Possession of Jewelry in Africa is a symbol of higher social status, the result shows that net of other factors, those who own jewelry are more likely to experience sleep disorder than those who do not possess jewelry (OR=1.69, $P<.001$), those who are obese show greater odds of sleep disorder than those with normal weight (OR=1.59, $P<.01$). Other significant differences were education, self-rated health, and feeling of happiness. These findings show that causal factors of sleep disorder among older adults are multifactorial and their underlying mechanisms may vary by geography(rural/urban)

SLEEP DISTURBANCE AMONG OLDER KOREAN IMMIGRANTS

Yeonsu Song,¹ Haesook Kim,² Diane Lee,³ Gery Ryan,⁴ B Josea Kramer,³ Jennifer Martin,⁵ Ron Hays,¹ and Sarah Choi,⁶ 1. *UCLA, Los Angeles, California, United States*, 2. *Holy Names University, Holy Names University, California, United States*, 3. *VA Greater Los Angeles Healthcare System, North Hills, California, United States*, 4. *Kaiser Permanente, Pasadena, California, United States*, 5. *VA Greater Los Angeles, Los Angeles, California, United States*, 6. *University of California, Los Angeles, Los Angeles, California, United States*

Little is known about sleep disturbance among older Korean immigrants living in the United States. In this exploratory study, we conducted focus groups with 6 and phone interviews with 22 older Korean immigrants to explore and understand their sleep experiences. Three members of the research team fluent in Korean independently coded each focus group and phone interview transcript to identify underlying themes. The following themes emerged: Daytime naps were acceptable behaviors, particularly among those who were retired or not employed. Many reported worry and anxiety rumination behaviors that interfered with their sleep. In addition, praying, reading the bible, and singing hymns often occurred while in bed, and smartphone or tablet use was a frequent activity as well. Drinking alcohol and taking sleeping pills were used as a last resort to help with sleep, particularly among those who lived alone. Internal (e.g., biological urge, snoring, medical conditions) and external distractions (e.g., noise) contributed to nighttime awakenings. Living alone and worrying about the future made it difficult for some to return to sleep after awakening. Seeking advice from peers was a common behavior but did not seem to help with sleep. Calming activities such as reading a book, taking a shower, watch television, or writing a diary were routinely performed before bedtime. These findings are consistent with unhealthy sleep behaviors shown in other racial/ethnic minority older adults with poor sleep. Sleep education programs in Korean-speaking churches may be used to target those who are socially isolated and may benefit older Korean immigrants.

TRENDS IN SHORT SLEEP DURATION IN THE NATIONAL HEALTH AND INTERVIEW SURVEY 2004-2018: A DECOMPOSITION ANALYSIS

Jiahui Xu,¹ Orfeu Buxton,² Liying Luo,³ Alyssa Gamaldo,³ Ashton Verdery,³ Melissa Hardy,² and Qian Xiao,⁴ 1. *Pennsylvania University, Pennsylvania, United States*, 2. *The Pennsylvania State University, The Pennsylvania State University, Pennsylvania, United States*, 3. *The Pennsylvania State University, University Park, Pennsylvania, United States*, 4. *The University of Texas Health Science Center at Houston, Houston, Texas, United States*

Since the early 2000s, it is increasingly common that people have short sleep durations (≤ 6 per 24-hour), making this a high-prevalence public health issue, especially among Black individuals. We investigate how trends in short sleep duration are influenced by changes in population aging, socioeconomic factors (e.g., education, labor force participation, marital status), and health conditions and behaviors (e.g., pain, smoking, drinking, obesity, psychological distress). We use the pooled cross-sectional data from the 2004-2018 National Health and Interview Survey, a large and nationally representative study. We partition overall trends in short sleep duration into (a) compositional effects due to distributional changes in age structure, socioeconomic and health factors and (b) unexplained rate effects. Subsequently, we compare the relative contribution of each factor to the total compositional effects among Black and White participants. Results demonstrate that greater education is associated with greater prevalence of short sleep duration among Black Americans, but reduced prevalence among White Americans. For both racial groups, population aging contributes relatively little to

temporal patterns in short sleep duration; by contrast, higher distress and lower labor force participation in recent years are associated with the increasing prevalence of short sleep duration.

WILL I FEEL THIS IN MY DREAMS? EXAMINING TEMPORAL ASSOCIATIONS BETWEEN DAYTIME AND DREAM AFFECT

Cassandra Richardson, Taylor Vigoureux, and Soomi Lee, *University of South Florida, Tampa, Florida, United States*

Despite the theory that dreams function to process emotions, few studies have examined how emotional experiences during daytime (“daytime affect”) are associated with the emotional tone of dreams (“dream affect”) that night, and vice versa. This study examined bidirectional associations between dream affect and daytime positive and negative affect. Participants were 84 nurses who completed two weeks of ecological momentary assessments. If participants remembered the previous night’s dreams (nparticipants=68; ndays=391), they reported the dream’s emotional tone upon waking (‘0’=very negative to ‘100’=very positive). Participants also responded to the Positive and Negative Affect Scale three times/day. Multilevel modeling simultaneously tested two temporal directions (daytime affect→dream affect, dream affect→daytime affect) at the within- and between-person levels. After adjusting for socio-demographic and work characteristics, at the within-person level, dream affect was more positive than usual on nights following more positive daytime affect ($B=0.25$, $p=.003$). In the other temporal direction, dream affect was not associated with the following day’s positive affect. At the between-person level, nurses who reported more positive dream affect also reported more positive daytime affect ($B=0.24$, $p=.025$). No associations emerged with negative affect. Findings suggest that daytime affect is associated with the emotional tone of that night’s dreams, but only in the context of positive affect. Importantly, negative affect was relatively low in this sample, so different patterns may emerge for people more prone to negative affect. Overall, these novel findings support the theory that dreams serve to process emotions, providing insight into the mystery of the function of dreams.

Social Determinants of Health and Aging (BSS Poster)

AGING MEN AND MASCULINITY IDEOLOGIES: VARIANCE COMPOSITION OF THE MRNS-BF AND MEASUREMENT INVARIANCE BY MEN’S AGE

Edward Thompson,¹ and Ronald Levant,² 1. *College of the Holy Cross, Broadview Heights, Ohio, United States*, 2. *University of Akron, University of Akron, Ohio, United States*

The construct traditional masculinity ideology (TMI, Levant & Richmond, 2016), like the construct dominant masculinities (Coles, 2009; Messerschmidt, 2019), refers to culturally-based principles about proper gender practices for men. The present study aimed to create a briefer and psychometrically stronger form of the Male Role Norms Scale

(MRNS), a long-standing and important measure of TMI. Using an archival data set ($N = 626$) with men age 25 and older, the MRNS was shortened using a set of recommended practices. Confirmatory factor analysis and assessment of measurement invariance showed the resulting MRNS-BF satisfies good fit principles with configural, metric, yet not reliable scalar invariance for age. It is a 6-item measure whose common factor measures TMI through two dimensions that mimic tenets Brannon (1976) and Connell (1995) theorized as underlying principles of masculinity ideologies in Western cultures: Earning and maintaining Respect/status, and No sissy stuff/avoidance of femininity in gender practices. Mean scores importantly show perhaps generational, certainly age cohort differences – aging men differed from established and middle-aged men by more moderately endorsing norms that specify men must strive to earn others' respect and the cultural emphasis on no sissy stuff. Younger age cohorts strongly adopted principles of gender equality. These observed differences must be interpreted with great caution, since the men in the three age groups did not seem to have a common zero point. Still, the MRNS-BF has good psychometric properties, and its brevity can assist future research on how gender guidelines influence aging men's health decisions and behavior.

ASSOCIATIONS BETWEEN NEIGHBORHOOD SES DISADVANTAGE AND FEELINGS OF DEPRESSION AND LONELINESS IN OLDER ADULTS

Dextiny McCain,¹ Adrienne Aiken Morgan,² and Regina Wright,³ 1. *North Carolina Central University, Durham, North Carolina, United States*, 2. *University of North Carolina at Chapel Hill, North Carolina, United States*, 3. *University of Delaware, University of Delaware, Delaware, United States*

Previous research suggests depressive symptoms and loneliness are increasingly prevalent among older adults living in lower-income neighborhoods. The purpose of this study was to examine the extent to which neighborhood socioeconomic status (SES) was associated with depressive symptoms and loneliness among a sample of older adults from the Healthy Heart and Mind Study ($N = 165$; mean age = 68.48 (SD = 6.26); 66.7% women; 40.6% African American). It was hypothesized that older adults living in neighborhoods with greater socioeconomic disadvantage would report more depressive symptoms and loneliness than those residing in neighborhoods with less socioeconomic disadvantage. Depression was assessed with the Beck Depression Inventory-II (BDI-II), and loneliness was assessed using the Revised University of California, Los Angeles (UCLA) Loneliness scale. Neighborhood SES was measured with the Area Deprivation Index (ADI), which allows rankings of neighborhoods by SES disadvantage both statewide and nationally. After controlling for demographic variables (age, sex, and race), linear regression analyses showed that greater neighborhood SES disadvantage was associated with higher depression scores ($\beta = -.094$; $p = .041$) and higher loneliness scores ($\beta = -.258$; $p = .003$). These findings highlight the importance of neighborhood context on mental health in older adults, as underserved populations are more likely to experience declines in mental health under strenuous circumstances. Future research should investigate the impact of neighborhood SES on mental health in aging adults.

FACTORS ASSOCIATED WITH THE USE OF TELEHEALTH IN MIDDLE-AGED AND OLDER ADULTS DURING THE COVID-19 PANDEMIC

Yan Du,¹ Rumei Yang,² Qingwen Xu,³ and Bo Xie,⁴ 1. *School of Nursing, University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States*, 2. *Nanjing Medical University, Nanjing, Jiangsu, China (People's Republic)*, 3. *New York University, New York University, New York, United States*, 4. *The University of Texas at Austin, Austin, Texas, United States*

The COVID-19 pandemic has promoted the adoption and use of telehealth, particularly in the early months of the pandemic. However, people with diverse characteristics may, or may not, be able to use telehealth, presenting digital divide in health care and potential health equity-related issues. This study aimed to assess the use of telehealth among middle-aged and older adults during COVID-19, and to explore factors associated with their telehealth utilization. We used publicly available data from the California Health Interview Survey collected during January 2019 and December 2020 ($N=15,279$; mean age = 64.23 ± 11.59 ; female: 52.7%). Approximately 11.0% of the sample used telehealth at least once. Bivariate and multivariate logistical regression analyses found that, compared with non-users, telehealth users were more likely to be having higher numbers of chronic conditions, with self-reported mental distress, living in urban areas, born in the US, with higher English proficiency, higher education, and having higher incomes. Age, race/ethnicity, and gender were not significantly correlated with telehealth usage. Logistic regression revealed that having mental distress (OR=1.48, 95% CI=1.29-1.71, $p<0.01$), more chronic conditions (OR=1.48, 95% CI=1.29-1.71, $p<0.001$) and living in an urban area (OR=1.93, 95% CI=1.36-2.74, $p<0.001$) were independently related to telehealth use. These findings suggest that telehealth, while being beneficial during the pandemic, might also introduce new challenges that exacerbate existing health inequity and disparities. Policy and community-based interventions are needed to promote the use of telehealth among middle-aged and older adults with diverse characteristics.

RACIAL/ ETHNIC AND GENDER DIFFERENCES IN OLDER ADULTS' CHRONIC STRESS PATTERNS

Kun Wang, and Zainab Suntai, *University of Alabama, Tuscaloosa, Alabama, United States*

Chronic stress has been associated with several adverse psychological, physical, and cognitive outcomes. While there exists a baseline level of stress among all individuals, certain groups of people are at risk of developing chronic stress due to existing hardships and stressors. Black Indigenous and/or people of color (BIPOC) and women have historically experienced several inequities including higher rates of certain chronic illnesses, interpersonal discrimination, socioeconomic disparities, and several other adverse outcomes. In addition to stressors from racial/ethnic and gender identities, older adulthood is a major transitional period marked by changes in physical, emotional, and cognitive well-being, which have been shown to affect overall well-being and mental health. As such, this study aimed to examine the association between chronic stress and cognition among older adults, using the intersectionality of race and sex. Data from the 2016 Health and Retirement Study were used, resulting in a final sample

of 6,015 adults aged 50 and older. Latent class analysis was used to determine chronic stress patterns by sex and race, and a three-step method was used to examine the effects of covariates on stress class memberships by race and sex subgroups. Results indicated that compared to White men, the high stress classes among White women, BIPOC men and BIPOC women contained more stressors. Interventions targeted towards the mitigation of chronic stress among older adults should consider how intersectional identities combine to create increased hardships and stressors.

TRAJECTORIES OF K-12 SCHOOLS AND DEMOGRAPHIC DIFFERENCES: EVIDENCE FROM 2017 LIFE HISTORY MAIL SURVEY

Wenshan Yu,¹ Xuefei Li,² and Jacqui Smith,³ *1. Institute for Social Research, University of Michigan (Ann Arbor), Ann Arbor, Michigan, United States, 2. Institute for Social Research, University of Michigan, Ann Arbor, Michigan, United States, 3. University of Michigan, University of Michigan, Michigan, United States*

Besides information about the highest degree, little information about early-life education is available in most population surveys. This study identified the trajectories of K-12 education history among older adults in the Health and Retirement Study born between 1930 and 1960, and examined the associations with demographic variables. Drawing on 2017 Spring and Fall Life History Mail Survey (LHMS; n = 3,206), we used sequence analysis to determine and classify trajectories of school types across the education history. We identified five trajectories: 1) always private school with White students, 2) always public school with White students, 3) always public school with Non-White students, 4) mostly private school with Non-White students, and 5) no report of school types. The trajectories showed that changes in school type (i.e. private to public) often happened in grade 9. Changes rarely happened across race/ethnicity groups (i.e. mostly White to mostly non-White). We used multinomial logistic regression to examine the relationship between demographic variables and education trajectories. We found that compared to Black participants, White participants were significantly less likely to be in mostly Non-White schools (public and private schools, $p < 0.001$). The 1940s and 1950s cohort were more likely to join mostly White private schools than the 1930s cohort (odds ratio: 1.70 for 1940s and 1.62 for 1950s separately, $p < 0.005$). Our findings illustrate a novel application of sequence analysis with life history data, as well as new evidence on racial segregation in early-life education within the last century.

Session 9450 (Poster)

Social Determinants of Health and Aging (SRPP Poster)

AREA DEPRIVATION SHARE: A NEW MEASURE OF SOCIAL NEED FACED BY HOSPITALS SERVING OLDER ADULTS

Kellia Hansmann,¹ Ryan Powell,² and Amy Kind,² *1. University of Wisconsin--Madison, Madison, Wisconsin, United States, 2. Geriatrics Division, Madison, Wisconsin, United States*

Medicare's Hospital Readmissions Reduction Program (HRRP) places disproportionate penalties on hospitals serving populations with complex medical and social needs. Without measures to identify the social need intensity of populations cared for by these hospitals, the HRRP cannot account for these risk factors, leading to burdensome penalties that may inadvertently hinder the ability of such hospitals to care for vulnerable populations. The objective of this study is to characterize the social need intensity of US hospital acute care populations. Using the Area Deprivation Index (ADI), a validated measure that ranks neighborhood socioeconomic disadvantage based on income, employment, housing, and education factors, we determined an "Area Deprivation Share" (ADS) for hospitals with 25 or more discharges using 100% of national Medicare claims data from 2013-2014. Hospital ADS is the proportion of qualifying discharges residing in the most disadvantaged neighborhoods ($ADI \geq 80$ th percentile) out of all qualifying discharges during the study period. Of 4,603 hospitals, median ADS was 17% (Interquartile Range: 6% - 34%). Hospitals in the highest quintile of ADS (39% to 100%), were more frequently located in small towns or isolated rural areas (52.6%, compared to 24.2% in lower quintiles) and served a higher percentage of Black patients (19.0%, compared to 9.7% in lower quintiles). ADS is a potential tool to inform future Medicare policy decisions. Additional research will inform how hospitals target care processes to meet the needs of older adults with complex social needs. Further study can also explore overlapping disadvantage domains of socioeconomic status, race, and rurality.

ASSOCIATION OF HOME BASED PRIMARY CARE ENROLLMENT WITH SOCIAL DETERMINANTS OF HEALTH FOR OLDER VETERANS

Anna-Rae Montano,¹ Augustus Ge,² Christopher Halladay,¹ Samuel Edwards,³ James Rudolph,¹ and Portia Cornell,¹ *1. Providence VA Medical Center, Providence, Rhode Island, United States, 2. Department of Veterans Affairs, Providence, Rhode Island, United States, 3. VA Portland Health Care System, Portland, Oregon, United States*

The Veterans Administration (VA) Home-based Primary Care (HBPC) program provides comprehensive primary care to older Veterans with multiple chronic conditions who may be at risk of adverse health outcomes due to their social determinants of health. Area Deprivation Index (ADI) can be used as a surrogate measure of a Veteran's social needs. The objective of this study was to estimate the effect of neighborhood disadvantage, as measured by ADI, on HBPC enrollment for a sample of older Veterans. We estimated a linear multivariate model in which the exposure was ADI and the outcome was enrollment in HBPC. Controls included clinical and demographic characteristics. In a final sample of 12,005,453 observations (total Veteran months) on 353,485 individual Veterans, 18.4% lived in high-deprivation neighborhoods (ADI greater than or equal to 80). Mean monthly probability of new HBPC enrollment was 0.0061. Controlling for clinical characteristics, housing instability, and distance from the medical center, Veterans residing in high-deprivation neighborhoods were 1.4% to 14.8% less likely to enroll in HBPC, though the association was not statistically significant. The VA HBPC program provides beneficial comprehensive, primary care services to Veterans at risk

of poor health outcomes. However, a Veteran's social determinants of health could prevent enrollment. More research is needed to determine the relationship between Veterans' social needs and HBPC enrollment.

ENGAGING STAKEHOLDERS IN A PRAGMATIC TRIAL OF HOME-DELIVERED MEALS FOR PERSONS WITH DEMENTIA

Jill Harrison,¹ Kathleen McAuliff,² and Kali Thomas,²
 1. *Brown University, Brown University, Rhode Island, United States*, 2. *Brown University, Brown University/ Providence, Rhode Island, United States*

Gathering stakeholder feedback is essential to designing and implementing relevant and actionable research. Additionally, stakeholders, particularly those directly impacted by an intervention, bring unique insights and experiences. This paper presents the process and findings of a research endeavor to co-design a pragmatic clinical trial with a Stakeholder Advisory Panel (SAP) in an effort to understand facilitators and barriers to conducting the research and implementing study findings. The proposed trial compares the impact of frozen, drop-shipped meals versus daily home-delivered meals provided by Meals on Wheels (MOW) programs on the ability of individuals living with dementia to age in place. We recruited nine SAP members, who were compensated for their time. The SAP is composed of a) MOW clients with dementia, b) family members of MOW clients with dementia, c) paid or volunteer MOW drivers, and d) MOW staff. A research team member facilitated two 90-minute meetings with the SAP members via Zoom. The topics of the meetings included potential benefits and challenges with each mode of meal delivery, the importance of the primary outcome (time to nursing home placement), topics of interest to include in interviews with clients and caregivers, and how participants would explain the study to a friend. Audio of the Zoom meetings was transcribed, and meeting summaries were shared with the SAP. Benefits of forming and engaging a SAP, as well as key lessons learned from SAP members and how recommendations were reflected in changes to the study protocol will be discussed.

INTERGENERATIONAL EDUCATION AND LATE-LIFE COGNITIVE DECLINE AMONG LATINOS AND NON-HISPANIC WHITES

Erika Meza,¹ Yea-Hung Chen,¹ Isabel Allen,¹
 Hector Gonzalez,² M Maria Glymour,³ and
 Jacqueline Torres,³ 1. *University of California, San Francisco, San Francisco, California, United States*,
 2. *University of California, San Diego, San Diego, California, United States*, 3. *University California San Francisco, San Francisco, California, United States*

Latinos face a growing burden of Alzheimer's Disease and related dementia (ADRD). Although education has been established as a strong predictor of ADRD, evidence to date is primarily for non-Latino cohorts. Few studies have assessed the relationship between intergenerational education and one's cognitive decline. Using the US Health and Retirement Study (N=20,860) we evaluated the joint effect of parental and own educational attainment on immediate and delayed verbal memory scores (range 0-10) from 1998 to 2016.

The exposure was a 4-category variable based on parents' (highest of mother's or father's) and participant's own high school attainment: first-generation (parents' education <12; own ≥ 12); multi-generation (both ≥ 12 : REF); neither graduated high school (both <12) and parent(s) graduated high school but not respondent (parents ≥ 12 ; own <12). Linear mixed effects models with subject-specific random intercepts and random slopes were stratified by race/ethnicity and tested for a 3-way interaction term (exposure x Latino x time). Models controlled for age, sex, place of birth and re-test effects. Baseline verbal memory scores did not differ for first-generation compared to multi-generation high school graduates. Verbal memory decline was faster for first- compared to multi-generation high school graduates among non-Hispanic whites (e.g., $\beta = -0.04$; 95% CI: -0.05, -0.03, delayed verbal recall); among Latinos, first and multi-generation high school graduates had similar rates of decline (e.g. $\beta = 0.00$; 95% CI: -0.03, 0.04, delayed verbal recall; $p < 0.001$ for three-way interaction). Our findings suggest social and economic policies that facilitate educational achievement, particularly for important population subgroups, may reduce ADRD risk.

TYOLOGY OF TRAUMATIC EVENTS AND PHYSICAL FUNCTION

Gabriella Dong, and Mengting Li, *Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States*

Individuals experience various traumatic events over the life course, but little is known about the patterns of lifetime exposure to traumatic events. This study aims to identify traumatic event typology and examine its relationship with physical function. Data were from the 2017-2019 PINE study (N= 3,125). Traumatic events were evaluated by earthquake, typhoon, tornado, residential fire, physical assault, robbery, sexual assault, divorce, bereavement, cancer, homeless, imprisonment, and falsely accused. Physical function was measured by activities of daily living (ADL), with lower scores indicating better physical function. Analysis was conducted using latent class analysis and the four-class model fits the data best. We identified four typologies: limited trauma, severe trauma, natural disaster, and mild-to-moderate trauma. The "limited trauma" (33.8%) has the lowest exposure to all traumatic events except typhoon and homeless. In contrast, an equivalent "severe trauma" (33.3%) has the highest exposure to all traumatic events except natural disasters. A small "natural disaster" (4.8%) has the highest exposure to natural disaster and moderate exposure to other traumatic events. The "mild-to-moderate trauma" (28.2%) has mild-to-moderate trauma exposures. The mild-to-moderate trauma group (M=0.38, SD=2.12) has better physical function than limited trauma (M=0.69, SD=3.08), severe trauma (M=0.61, SD=2.81), and natural disaster (M=0.71, SD=3.22) groups. After controlling confounding variables, the mild-to-moderate trauma group has lower risks of ADL impairment than the limited trauma group (OR=0.66, 95% CI=0.47-0.93). The findings suggest mild-to-moderate exposure to traumatic events might benefit older adults' health, while limited trauma might not be able to develop resilience and severe trauma overwhelms coping strategies.

Session 9455 (Poster)

Social Support, Social Connectedness, and Loneliness I

CUMULATIVE EFFECT OF LONELINESS AND SOCIAL ISOLATION ON HEALTH OUTCOMES AMONG OLDER ADULTS

Timothy Barnes,¹ Stephanie MacLeod,² Rifky Tkatch,³ Manik Ahuja,¹ Laurie Albright,⁴ James Schaeffer,¹ and Charlotte Yeh,⁵ 1. *UnitedHealth Group, Minnetonka, Minnesota, United States*, 2. *UnitedHealth Group, United States*, 3. *UnitedHealth Group, Oak Park, Michigan, United States*, 4. *UnitedHealth Group, Minneapolis, Minnesota, United States*, 5. *AARP Services, Inc., Washington, District of Columbia, United States*

Loneliness and social isolation are described similarly yet are distinct constructs. Numerous studies examine each construct separately; however, less research has been dedicated to exploring their impacts together. Using survey and claims data among adults age 65+ (N=6,994), the cumulative effects of loneliness and social isolation on late-life health outcomes were examined using Chi-square and multivariate regression models. Loneliness and social isolation were measured using the UCLA-3 Loneliness Scale and the Social Network Index. Participants were grouped into four categories of loneliness and social isolation based on overlap, including: lonely only (L), socially isolated only (SI), both lonely and socially isolated (LSI), or neither (N). Outcomes included quality of life and healthcare utilization and costs. Among participants, 9.8% were considered L, 20.6% SI, 9.1% LSI, and 60.5% N. Respondents were primarily female (55.0%) and 70-74 years of age (27.1%). Those considered LSI were more likely to be older, female, less healthy, depressed, with lower quality of life and greater healthcare utilization patterns. Participants who were L or LSI had higher rates of emergency room visits compared to the N group; LSI had the highest medical costs. Results demonstrate the cumulative effects of loneliness and social isolation among older adults. Findings not only fill a gap in research exploring the impacts of these constructs later in life, but also confirm the need for approaches targeting older adults who are both lonely and socially isolated. As the COVID-19 pandemic continues, this priority will continue to be urgent for older adults.

EVALUATION OF A WEB-BASED WELLNESS PROGRAM TO REDUCE LONELINESS AMONG OLDER ADULTS

Rifky Tkatch,¹ Lizi Wu,² Laurie Albright,³ and Charlotte Yeh,⁴ 1. *UnitedHealth Group, Oak Park, Michigan, United States*, 2. *UnitedHealth Group, Minnetonka, Minnesota, United States*, 3. *UnitedHealth Group, Minneapolis, Minnesota, United States*, 4. *AARP Services, Inc., Washington, District of Columbia, United States*

Background: Loneliness has been associated with adverse health outcomes, including increased mortality risk. Interventions aimed at addressing maladaptive social cognition have documented efficacy in reducing loneliness among

older adults. Purpose: The purpose of this study was to determine the feasibility and efficacy of a web-based wellness program in reducing loneliness and improving psychosocial health among older adults with an AARP® Medicare Supplement plan insured by UnitedHealthcare Insurance Company. Methods: Eligible individuals were 65 years and older, who self-identified as lonely on a prior survey, and indicated that they had access to the internet through a computer or smartphone. Participants completed up to eight online modules comprised of a short lesson on an aspect of maladaptive social cognition, followed by a comprehension quiz, selection of a short-term goal, and a phone or text chat with a program coach. Four surveys were administered to assess the effects of program participation: (1) prior to the start of the program, (2) after completion of four online modules, (3) after completion of all eight modules, and (4) 30-60 days later. Results: Attrition was high. Overall, 220 (42%) program participants completed both T1/T2 surveys, 193 also completed a T3 survey, and 177 also completed a T4 survey. Post-survey data indicated that loneliness and perceived stress decreased while mental wellbeing, resilience, and perception of aging improved. Conclusion: Digital interventions aimed at addressing maladaptive social cognition offer potential to reach lonely older adults and support psychosocial wellbeing through reduced loneliness.

EXPLORING SOCIAL SUPPORT SYSTEMS AND EXPERIENCES OF OLDER WOMEN IN TEDE COMMUNITY, OYO STATE, NIGERIA.

Kafayat Mahmoud, *University of Kansas, Lawrence, Kansas, United States*

Rural communities in Nigeria are rapidly aging due to the massive movement of young adults to the cities, especially after marriage and/or in search of employment. This has adversely affected the social supports for older persons. The current study explored the experiences of older adults living in rural communities in Southwestern Nigeria. The study adopted an exploratory qualitative research design, in-depth interview techniques were adopted, and results were analyzed using thematic analysis. For this pilot study, conducted in Tede community in Oyo state in Nigeria, 10 older women, aged 70+ years were purposively selected for the study. The fact that all participants were women was due to the fact that older persons found in the community were mostly women. Consonant with previous research, this pilot study found that there was limited formal and informal support systems for older women in the community. The study additionally revealed that older women expressed feelings of abandonment by adult children, having insufficient funds, as well as inability to access health care. Consequently, these women resorted to alternative means to fend for themselves. For instance, despite having functional limitations, older women in the community would engage in physically demanding tasks such as going into the bushes to cut and gather firewood to sell, as well as engaging in other forms of petty trading, while others resorted to begging for alms for sustenance. This pilot study highlights the experience of poverty among older women and the need for more structural interventions for older persons in Nigeria.

LIVING/EATING ARRANGEMENT, LONELINESS, AND MENTAL DISTRESS AMONG OLDER KOREAN IMMIGRANTS: GENDER DIFFERENCE

Nan Sook Park,¹ Yuri Jang,² Soondool Chung,³ David Chiriboga,¹ and William Haley,¹ 1. *University of South Florida, Tampa, Florida, United States*, 2. *University of Southern California, Los Angeles, California, United States*, 3. *Ewha Womans University, Ewha Womans University, Seoul-t'ukpyolsi, Republic of Korea*

Structural isolation such as living alone poses a mental health risk in diverse groups of older adults, including older immigrants. Given that those living with others might also be disengaged, the present investigation included eating alone as another source of isolation and examined the impact of the combination of living and eating alone. The purposes of the study were to examine (1) how living and/or eating alone would impact mental distress, (2) whether the impact would be mediated by feelings of loneliness, and (3) if there would be gender differences in the mediation effect. The data were drawn from the Study of Older Korean Americans (SOKA), which surveyed older Korean immigrants in five states during 2017–2018. The living/eating arrangement was classified into four-groups: living/eating with others (57%), living with others/eating alone (12.4%), living alone/eating with others (7.3%), and living/eating alone (23.1%). Using the PROCESS macro, we tested the mediation effect of loneliness and the moderation effect of gender in the relationship between the typology and mental distress controlling for background/health characteristics and social capital related variables. Two groups (living with others/eating alone and living/eating alone) had sociodemographic, health, and social capital disadvantages. Analyses demonstrated that mental distress was linked with living with others/eating alone and living/eating alone, of which relationships were mediated by loneliness only among women. Findings suggest that not only structural isolation (e.g., living alone) but also disengagement with others (e.g., eating alone) need to be considered to understand emotional well-being in older immigrant population and gender difference.

LONGITUDINAL RELATIONSHIP BETWEEN LIVING ALONE AND ACTIVITY ENGAGEMENT OF CHINESE OLDER ADULTS

Fengyan Tang,¹ and Ke Li,² 1. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*, 2. *University of Pittsburgh, Sandy Springs, Georgia, United States*

The living arrangement of older adults plays a key role in their health status and psychological well-being. Yet the relationship between living arrangement and activity engagement remains unclear. Using data from three waves of the nationally representative China Health and Retirement Longitudinal Study (CHARLS) with a study sample of 7,479 respondents aged 60 or older, this study examined the effect of living alone on the frequency of activity engagement among Chinese older adults. Two types of activity engagement were examined in this study, including social interaction with friends and leisure activity (i.e., play chess, go to a sport or club). The multinomial logistic regression analyses were performed using generalized structural equation modeling (GSEM). Compared with those living with others, older adults living alone were older, more likely to be female and

living in urban areas, and with fewer years of education and more functional limitations. The results also indicated that after controlling for a set of covariates, living alone status was significantly associated with the increased likelihood of high and medium frequency of both social interaction and leisure activity in reference to no engagement. This study not only improves the understanding of activity engagement preference of Chinese older adults who are living alone but also indicates the importance of improving community facilities and outdoor spaces to promote activity engagement among older adults.

MARITAL SUPPORT RECIPROCITY AND LIFE SATISFACTION AMONG OLDER KOREANS

Hye Soo Lee, *Oregon State University, Corvallis, Oregon, United States*

The importance of reciprocity in social support for well-being has been shown, but few studies have investigated marital support reciprocity in older Korean samples. This study examined the associations between three types of marital support reciprocity and life satisfaction, stratified by age and gender. The sample consisted of 1,578 men and 1,464 women from the 2017 National Survey of Older Koreans, divided into young-old (65-74) and old-old (75+) groups (M age = 75.06, SD = 6.35). Participants self-reported emotional, instrumental, and physical support provided to and received from spouses, and life satisfaction (LS). Regression models controlling for covariates showed that results varied by age and gender. For young-old males, received emotional and provided instrumental support were positively associated with LS. For young-old females, both received and provided emotional support, and received instrumental support, were positively associated with LS, but provided physical support showed negative associations. For old-old males, providing emotional support was positively associated with LS; for old-old females, only received emotional support was significant. Using interaction terms to assess reciprocity, young-old females and old-old males showed reciprocity effects for instrumental support. When participants provided and received high levels of support, life satisfaction levels were high. However, when participants provided low levels of support, received support was not significant. Thus, the effects of receipt and provision of support on LS varied by age and gender among older Koreans, but reciprocity of instrumental support was only important for young-old women and old-old men.

POSITIVE PERIPHERAL SOCIAL NETWORK MEMBERS IN OLDER AGE: GLOBAL AND DAILY APPRAISALS OF SOCIAL PARTNERS

Claire Grownney,¹ and Tammy English,² 1. *Washington University in St. Louis, Saint Louis, Missouri, United States*, 2. *Washington University in St. Louis, St. Louis, Missouri, United States*

Socioemotional selectivity theory suggests older adults maintain relationships with close social partners with whom they experience positive emotions. It is unclear how age and closeness predict social partner appraisals in different contexts. We examine semantic and experiential appraisals of positivity, as well as emotional outcomes. Participants (N = 258) aged 25-85 (M = 52.05, SD = 16.31) reported

their general experience of enjoyment and conflict with social partners of varying closeness. In an experience sampling procedure (6x/day for 10 days), participants reported their current experience of emotions and information about their most recent social interaction: pleasure, discomfort, and relationship closeness with their social partner. Semantic (global) appraisals of relationships positively predicted experiential (daily) appraisals, and this association was stronger among relatively older adults. Results revealed older adults gave less negative appraisals compared to younger adults, regardless of closeness. Older adults reported more positive appraisals than younger adults for non-close relationships, whereas close relationships were evaluated positively regardless of age. For younger adults, interaction pleasure with non-close partners was less strongly linked to subsequent positive emotions than pleasure with close partners. For older adults, however, interaction pleasure predicted greater subsequent positive emotions regardless of relationship closeness. Overall, these findings suggest older adults' positive appraisals of partners are not simply the result of emotionally gratifying memory distortions. Older adults may be able to derive emotional benefits from a wider variety of social interactions than younger adults, suggesting peripheral social network members can be leveraged to enhance emotional well-being in later adulthood.

PRELIMINARY IMPACT OF A SOCIAL CONNECTION PROGRAM ON OLDER ADULTS

Rachel Ungar,¹ Rifky Tkatch,² Yan Cheng,¹ Sandra Kraemer,³ Michael McGinn,¹ and Ellen Wicker,⁴
 1. *UnitedHealth Group, Minnetonka, Minnesota, United States*, 2. *UnitedHealth Group, Oak Park, Michigan, United States*, 3. *UnitedHealthcare, Minnetonka, Minnesota, United States*, 4. *AARP Services, Inc., Washington, District of Columbia, United States*

Background: Research demonstrates social connections decrease loneliness and improves life satisfaction among older adults. Unfortunately, the COVID-19 pandemic has limited social connectedness, specifically for older adults. Thus, programs aiming to increase social connectedness among older adults are imperative. **Purpose:** The primary objective of this study was to determine if the telephonic Peer-to-Peer (P2P) program can improve social connectedness and loneliness among older adults. A secondary objective was to determine whether additional improvements in life satisfaction and perception of aging were achieved. **Methods:** Eligible older adults (age 65+) were recruited via outbound calls and/or a mailer. Participants were mailed a T1 survey, completed intervention training, and matched into a dyad. The matched dyad engaged in weekly telephone calls for 12 weeks. Post 12 weeks, participants completed a T2 survey, and a T3 four weeks later. **Results:** Overall, 7,544 individuals were contacted to participate, and 759 expressed interest in participation. A total of 475 participants (62%) completed a T1, 372 (78%) completed training, and 348 (94%) were matched. Gender distribution was skewed towards females (74%), and most were 65-74 years old (53%). Preliminary results show significant differences between lonely and not lonely participants, with lonely participants reporting more negative health associations across all measures. **Conclusion:** Once agreeing to participate, results showed a high likelihood

of continuing in P2P, thus demonstrating a social connectedness opportunity for older adults. Delay in mailing and scheduling training may contribute to challenges in attrition. However, developing automated processes utilizing technology may decrease lag time for future phases.

SOCIAL CONNECTEDNESS AND COMMUNICATION TECHNOLOGY AMONG PAID AND UNPAID CAREGIVERS OF MIDDLE-AGED AND OLDER ADULTS

Shinduk Lee,¹ Marcia Ory,² Deborah Vollmer Dahlke,³ and Matthew Smith,⁴
 1. *University of Utah College of Nursing, Utah, United States*, 2. *Texas A&M University, College Station, Texas, United States*, 3. *DVD Associates, LLC, DVD Associates, LLC, Texas, United States*, 4. *Texas A&M School of Public Health, College Station, Texas, United States*

Objective: To examine differential relationships between communication technology use and social connectedness among paid and unpaid caregivers providing care for middle-aged and older adults. **Methods:** This nationwide study utilized a cross-sectional Qualtrics panel survey from caregivers, ages 50 years and older (n=504) of middle-aged and older adults. About 17% were paid (n=86) and 83% (n=418) were unpaid caregivers. Primary outcomes were caregivers' sense of belonging to their local community and social bonds. The primary predictor of interest was caregivers' use of communication technology (texting/communication applications). A multivariable regression analysis was performed to predict each outcome based on communication technology use, separately among paid and unpaid caregivers. Multivariable regression analyses were repeated after including the caregivers' payment status (paid/unpaid) and the interaction term between the caregivers' payment status and the use of communication technology. The models were adjusted for caregivers' age, education, financial status, place of residence, and total weekly hours of caregiving. **Results:** Use of communication technology had a statistically-significant positive association with sense of belonging only among paid caregivers (b=25.8, p=.005). The relationship between use of communication technology and sense of belonging was significantly different between paid and unpaid caregivers (p=.005). Use of communication technology was significantly associated with social bonds only among unpaid caregivers (b=0.4, p<.001). There was no statistically-significant differential association between communication technology use and social bonds. **Conclusion:** Communication technology may play differential roles in linking paid and unpaid caregivers with their community and interpersonal groups. Additional efforts should examine mechanisms that provide meaningful caregiver support.

SOCIAL SUPPORT AND WEIGHT OUTCOMES OVER A SIX-MONTH WEIGHT LOSS INTERVENTION FOR RURAL OLDER ADULTS

Anna Kahkoska,¹ Curtis Petersen,² David Lynch,³ Hillary Spangler,⁴ Karen Fortuna,² and John Batsis,⁵
 1. *University of North Carolina at Chapel Hill, University of North Carolina at Chapel Hill/Chapel Hill, North Carolina, United States*, 2. *Dartmouth College, Lebanon, New Hampshire, United States*, 3. *University of North*

Carolina, Chapel Hill, North Carolina, United States, 4. UNC Hospitals, Chapel Hill, North Carolina, United States, 5. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States

Rural older adults aged ≥ 65 years with obesity (body mass index (BMI) ≥ 30 kg/m²) showed an overall favorable response to a six-month, technology-based weight-management intervention. Our objective was to characterize how friends or family support for eating and exercise behaviors at baseline was associated with baseline weight and intervention response. We analyzed data from six subscales of the Social Support and Exercise Survey from 44 participants. Six-month weight change ($\geq 5\%$ of baseline) was considered clinically-significant. For each subscale, continuous and categorical outcomes were modeled with linear and logistic regression models, respectively, adjusted for sex and age. Crude associations of social support clusters, generated in an exploratory hierarchical cluster analysis, and weight outcomes were evaluated. The sample was 73.2 ± 3.9 years, 73% female, with mean baseline weight 97.8 ± 16.3 kg and BMI 36.5 ± 5.2 m/kg². Family encouragement for healthy eating was negatively associated with baseline weight ($\beta = -0.53$, $p = 0.046$). Social support scores were not associated with either six-month weight loss outcome ($p > 0.10$). Two exploratory clusters were found: Cluster 1 (C1) ($n = 34$) and Cluster 2 (C2) ($n = 9$). C2 had higher mean social encouragement and discouragement, with lower mean baseline weight (90.0 ± 11.7 vs 99.8 ± 16.8 kg C1; $p = 0.10$). Weight loss was comparable (C1 4.6 ± 3.7 versus C2 4.8 ± 2.6 kg; $p = 0.89$), with no differences in clinically-significant weight loss (C1 45% versus C2 67%; $p = 0.46$). These pilot data suggest that family member social support may act as collaterals to support clinical outcomes in the community. Evaluating different types within family support may elucidate associations with physiological outcomes in larger samples.

THE ROLE OF SOCIAL CONNECTION/ENGAGEMENT PREDICTS CHANGES IN DEPRESSIVE SYMPTOMS AND IADL IN STROKE

Joanne Elayoubi,¹ and Monica Nelson,² 1. *USF, land o lakes, Florida, United States*, 2. *University of South Florida, Brandon, Florida, United States*

Social connections/engagement have been found to be potentially protective against depression and declines in physical functioning. We examined whether social connection/engagement was protective against depression and functional decline after stroke. Participants were 898 individuals with incident stroke from the Health and Retirement Study between 1998-2012. Multilevel modeling was used to examine how social connection/engagement were associated with trajectories of depressive symptoms and limitations with instrumental activities of daily living (IADLs). Models controlled for age, gender, education, and race. In addition, analyses with depressive symptoms as outcome controlled for functional limitations with ADLs. Participants who were lonely and did not have friends in their neighborhood pre-stroke had more depressive symptoms at the time of stroke. Participants with close children pre-stroke showed less increase in depressive symptoms over time. Within-person increase in loneliness and within-person decline in providing help were related to more depressive symptoms post-stroke. Participants who felt

lonely and did not provide help pre-stroke had more IADL limitations at the time of stroke. Smaller pre-stroke household size and pre-stroke volunteering were associated with less increase in IADL limitations with stroke. Within-person increase in having friends and providing help after stroke were associated with fewer IADL limitations post-stroke. Taken together, these findings suggest that social connection/engagement may buffer the negative psychological and physical outcomes of a stressful event such as stroke.

WHO NEEDS A FRIEND? HOW AGE AND HAVING SOMEONE ONE CAN COUNT ON EXPLAIN SUBJECTIVE WELL-BEING IN INDIA

Erika Sanborne, *University of Minnesota--Twin Cities, West Saint Paul, Minnesota, United States*

Subjective well-being is now considered a reliable predictor of many desirable outcomes not only at the individual level, in terms of one's personal health, but also at the national level, in terms of a nation's per capita gross domestic product, progress towards reaching sustainable development goals, and other metrics. Subjective well-being has several known causes that reliably predict well-being across time and place, such as income, education, prosociality, and perceived corruption (i.e. REF). Given the benefits of well-being to both individuals and nations, and that subjective well-being is often predicted by variables that are not easily altered, this study aims to better understand the relationships between subjective well-being and some of its known predictors, in the context of India. Three hypotheses were tested and found significant with nationally representative samples of a total of 57,077 survey respondents in India, using data from Gallup World Poll for 2006-2019. Hypothesis #1 tests for having someone one can count on as a mediator. Hypothesis #2 tests for age as a moderator. Hypothesis #3 is a moderated mediation that best explains how the known predictors of subjective well-being make their influence, and with whom. This study's findings give insights into the ways in which subjective well-being in India can be better understood and thus improved. Such understanding may also help local Indian nonprofit organizations, as well as other researchers and mental health providers, with shared interests in the growing prevalence of suicide in India.

Session 9460 (Poster)

Social Support, Social Connectedness, and Loneliness II

BIRTH OF THE SOCIETY OF DIVOREES – CHANGING PATTERNS OF CIVIL STATUS IN LATER LIFE

Torbjorn Bildtgard,¹ and Peter Öberg,² 1. *Stockholms University, Stockholm, Stockholms Lan, Sweden*, 2. *University of Gävle, Gävle, Gavleborgs Lan, Sweden*

Half a century ago Lopata used the concept “society of widows” to describe the gendered reality of late life singlehood, where widowed women were excluded from coupled social life, depended on a community of other widows for social integration, and refrained from initiating new relationships due to “sanctification” of their former husbands. We use Swedish, American and EU census data and

a national survey to Swedes 60-90 years old ($n=1225$; response rate 42%) to illustrate a substantial change in the demographic landscape of late life singlehood. More people enter later life as divorcees or become divorced at a high age. Among Swedes 60+ divorcees outnumber widowed people, and the incidence of late life divorce has more than doubled since the millennium in what has been called the “grey divorce revolution”. Many other Western countries follow the same demographical trend, posing important questions about the transformation of late life singlehood. Based on two Swedish studies we will show that the structure of the late life single community is becoming less gender skewed as a consequence of the emerging society of divorcees, and that in this society relationship careers are increasingly complex, attitudes to repartnering increasingly liberal and partner sanctification seldom an issue. We conclude by proposing the concept “society of divorcees” for this new demographic landscape of late life singlehood, argue that research is needed to capture this new reality, and discuss the implications of this change for access to social support later life.

EFFECTS OF LONELINESS AND STRESS MANAGEMENT ON PERCEIVED STRESS IN OLDER ADULTS

Angela Gifford,¹ Hayley Fouche,² and Janelle Beadle,²

1. *University of Wisconsin-Madison, Madison, Wisconsin, United States*, 2. *University of Nebraska at Omaha, Omaha, Nebraska, United States*

In older adulthood, individuals may experience acute and chronic stressors, such as the loss of independence, mobility, or the experience of chronic diseases. Loneliness is also a concern in older adulthood as many experience the loss of close others and smaller social networks. Loneliness is well-established as being associated with higher stress levels in younger adults, but there are mixed findings on the impact in older adulthood. Furthermore, while older adults may engage in behaviors designed to reduce and manage stress, it is not known whether these behaviors modulate the relationship between loneliness and chronic stress. The current study examined the relationship between loneliness and stress in older adulthood and the degree to which stress-management moderated this relationship (note: data collected prior to COVID-19 pandemic). We hypothesized that loneliness and perceived stress would be positively associated, but that stress-management would moderate this relationship. Participants included 40 healthy older adults ($M_{age}=69.18$, Range:55-86yrs; 29 females) who completed the UCLA-Loneliness Scale, the Perceived Stress Scale, the NEO-FFI (to assess neuroticism), and demographic information about participation in stress management activities. We found that loneliness was significantly associated with chronic stress, $r(38) = .517$, $p < .001$. Furthermore, loneliness and neuroticism were significant predictors of perceived stress, $F(2, 37) = 9.618$, $p < .001$, $R^2 = .342$. These findings demonstrate that loneliness is a significant predictor of perceived stress in older adulthood and point to a need for further exploration of effective stress-management tools in later life.

ENHANCING GROUP BONDING IN AN ACTING CLASS OF OLDER ADULTS IN URBAN SUBSIDIZED HOUSING

Laura Sutherland,¹ Ruth Dunkle,² and Garrett Pace,²

1. *Wayne State University, Ann Arbor, Michigan, United*

States, 2. *University of Michigan, Ann Arbor, Michigan, United States*

Creative arts such as acting can promote social contact and bonding among socially isolated populations. Yet the benefits of art programming among older adults in low-income urban settings remain unexplored. A professionally administered theater group comprised of older adults living in urban low-income housing met for 12 weeks to learn acting skills and perform a play. The purpose of this study was to identify: 1) why participants enroll in a residence-based acting and improvisation course, and 2) what aspects of the course contribute to group bonding. Participants ($n=14$) were African American. The average age was 63 years, 14% were men, 57% had a high school degree or less, 79% reported good to excellent health, and the mean ADL score was 1.45 (range: 1-2.5). A researcher was present at each class session to observe and take field notes. Pre-post interviews included closed and open-ended questions. The researchers reviewed field notes and interview transcripts for a priori themes and emergent themes through independently coding data, discussing similarities and discrepancies, and coming to consensus on themes. Results showed that participants were motivated to enroll to meet new people, come out of themselves, learn something new, and gain artistic skills. Participants indicated the course contributed to group bonding via teaching techniques, course structure, the teacher's use of self, the expression of self, and mutually enhanced coping skills. Results from this study provide guidance for the design of theater groups in similar settings and inform recruitment efforts of older adults in creative arts programs.

EVALUATING THE VALIDITY OF THE COLUMBIA-SUICIDE SEVERITY RATING SCALE FOR LONELY OLDER ADULTS

Jacqueline Mai,¹ Emily Bower,¹ and Kimberly Van Orden,²

1. *Pacific University, Hillsboro, Oregon, United States*, 2. *University of Rochester Medical Center, University of Rochester Medical Center, New York, United States*

The risk of suicide death represents a significant problem facing older adults. They are less likely to disclose suicidal ideation (SI) and more likely to die from a suicide attempt compared to younger populations. Accurate screening tools for suicide risk are necessary to identify high-risk individuals who could benefit from intervention. The Columbia-Suicide Severity Rating Scale (C-SSRS), considered the gold standard for clinician-administered suicide risk assessments, was not developed for use with older adults. The purpose of this investigation is to evaluate the C-SSRS's sensitivity in capturing previous suicidal behavior (behavior subscale) and current intent (severity subscale), both of which are highly predictive of suicide in older adults. 105 adults 60 years and older ($M=72.10$, $SD=9.16$; 68.6% female) who endorsed loneliness or feeling like a burden in the past two weeks were enrolled in a larger controlled trial and completed baseline C-SSRS, Quick Inventory of Depressive Symptoms (QIDS), and Geriatric Suicide Ideation Scale (GSIS). Exclusion criteria included significant cognitive impairment. Concurrent validity will be evaluated using random-effects mixed linear regression to test associations between C-SSRS scores and GSIS and QIDS scores, respectively. Baseline responses indicate that 14.9% of participants reported at least one lifetime suicide attempt. Within the last month, 66.7% wished to be

dead, 20% had active SI without a plan, 6.7% had active SI with some intent to act, and 6.7% had active SI with a specific plan and intent. Findings from this project will help guide safety assessment recommendations and inform interventions targeting older adult suicide risk.

LONELINESS, SOCIAL ISOLATION AND ALL-CAUSE MORTALITY IN OLDER ADULTS

Timothy Barnes,¹ Rifky Tkatch,² Manik Ahuja,¹ Laurie Albright,³ James Schaeffer,¹ and Charlotte Yeh,⁴
 1. *UnitedHealth Group, Minnetonka, Minnesota, United States*, 2. *UnitedHealth Group, Oak Park, Michigan, United States*, 3. *UnitedHealth Group, Minneapolis, Minnesota, United States*, 4. *AARP Services, Inc., Washington, District of Columbia, United States*

As distinct constructs, loneliness and social isolation have both been associated with mortality in older adults. Many studies have examined each construct separately; however, few have examined their impact together, especially within the U.S. Using data from a large sample of U.S. adults age 65+ (N=7,982), the effect of loneliness and social isolation on all-cause mortality was examined considering their separate and joint effects. Measures were based on the UCLA-3 Loneliness Scale and the Social Network Index (SNI). Loneliness was categorized as: Severe, moderate, or no loneliness. Social isolation (defined by the SNI) was categorized as: Limited, medium, or diverse social networks (SN). Cox proportional hazards regression models were performed. Among participants, there were 328 deaths after data collection (4.1%). In separate, adjusted models, loneliness (severe, HR=1.86, 95% CI: 1.43-2.41 and moderate, HR=1.51, 95% CI: 1.16-1.98) and social isolation (limited SN, HR=2.37, 95% CI: 1.72-3.27 and moderate SN, HR=1.55, 95% CI: 1.12-2.14) were both associated with mortality. Modeled together, loneliness (severe, HR=1.55, 95% CI: 1.18-2.04 and moderate, HR=1.40, 95% CI: 1.07-1.83) and social isolation (limited SN, HR=2.08, 95% CI: 1.49-2.89 and moderate SN, HR=1.46, 95% CI: 1.05-2.02) both remained significantly associated with all-cause mortality with limited SN as the stronger indicator. Results demonstrate that both loneliness and social isolation contribute to greater risk of mortality among older adults. Furthermore, individuals with limited SN are at greatest risk. As the COVID-19 pandemic continues, loneliness and social isolation should be targeted safely in efforts to reduce mortality risk among older adults.

LOW FRIEND CONNECTION LEADS TO LOW FUNCTIONAL CAPACITY OF OLDER ADULTS: FINDINGS FROM A 2-YEAR LONGITUDINAL STUDY

Mai Takase,¹ Kyo Takahashi,¹ Ryogo Ogino,² Tomoki Tanaka,³ Jun Goto,⁴ and Katsuya Iijima,³
 1. *The University of Tokyo, Bunkyo-ku, Tokyo, Tokyo, Japan*, 2. *Saga University, Saga, Saga, Japan*, 3. *The University of Tokyo, Bunkyo-ku, Tokyo, Japan*, 4. *Tokai University, Hiratsuka, Kanagawa, Japan*

Maintaining personal connections in geriatric years is important to sustain the functional capacity of older adults. In this study, we define the term functional capacity as the ability to perform tasks and activities necessary for one's independent life. Meanwhile, the type of personal connection and its effect on functional capacity remain unclear.

We classified personal connections into connections with family or friends and examined their association with the functional capacity of independently living Japanese older adults. A two-year longitudinal study (2016 and 2018) was conducted using data from the Kashiwa Cohort Study. The amount of personal connections was determined using the Lubben Social Network Scale. The Japan Science and Technology Agency Index of Competence was used to assess participants' functional capacity. The change in functional capacity was analyzed by binomial logistic regression analysis (N=638, reference: group with high family and friend connection). The results showed a decline in the functional capacity of the group with low friend and family connections (odds ratio (OR): 0.48, 95%CI: 0.29-0.82). This trend was also seen for the group with a high family connection but low friend connection (OR: 0.43, 95%CI: 0.24-0.78). Meanwhile, there was no significant difference between the reference group and the group with low family but high friend connection (OR: 0.85, 95%CI: 0.47-1.56). The results imply the importance of having a friend for sustainable functional capacity in old age. Interventions that facilitate friend-to-friend interactions or promote new friendships among older adults can be considered as support strategies.

NEED TO BELONG AND SOCIAL TIES IN LATE LIFE

Zexi Zhou, Yijung Kim, Shiyang Zhang, and Karen Fingerma,
The University of Texas at Austin, Austin, Texas, United States

According to socioemotional selectivity theory, older adults are more selective and tend to shrink their social network to their closest ties. However, a heightened need to belong, which is characterized by a stronger desire for acceptance and motivation to affiliation, may alter this common pattern. We know little about how the need to belong shapes social network structure, especially in late life. This study investigated the associations between the need to belong, size of social network, and engagement with social ties among older adults. Participants (N = 314) aged over 65 years from the Daily Experiences and Well-being Study completed a baseline interview regarding their close ties (i.e., social convoy members), and weak ties, as well as a self-report measure of need to belong. They completed ecological momentary assessment (EMA) surveys reporting their social encounters every 3 hours over 5 to 6 days. Need to belong was unrelated to the number of close ties. In contrast, participants with a higher need to belong reported more less close (but still important) ties and weak ties than those with a lower need to belong, but spent a similar amount of time (i.e., proportion of EMA involving social encounters) with either their close ties or weak ties. These results suggest that the need to belong may motivate older adults to go beyond their closest ties to weaker ties, and highlight the discrepancies between the sense of being connected to social partners and the actual engagement with them in this process.

NURSING STUDENTS VISITING PEOPLE WITH DEMENTIA ONLINE DURING COVID-19: A QUALITATIVE STUDY

Michelle Kimzey,¹ Jodi Patterson,² and Beth Mastel-Smith,³
 1. *Harris College of Nursing & Health Sciences (Texas Christian University), Fort Worth, Texas, United States*,

2. TCU, Fort Worth, Texas, United States, 3. University of Texas at Tyler, Tyler, Texas, United States

The coronavirus disease 2019 (COVID-19) crisis has impacted the daily routines of students, people living with dementia, and their care partners. Social distancing results in fewer interpersonal interactions and enjoyable activities which makes life more challenging for those living with dementia. The purposes of this multiple case study were to understand how nursing students, people with dementia, and care partners (a) describe online visits between nursing students and people with dementia during stay-at-home directives in response to COVID-19 and (b) the perceived visit benefits. Nursing students participated in online visits to socially engage with their mentor (person living with dementia). During the visits it was anticipated that care partners would enjoy a brief respite. After 12 visits, investigators completed one-to-one online interviews with students ($n = 10$), care partners ($n = 8$) and mentors ($n = 8$). All cases reported a positive experience, perceptions of the conversations, improved social connection and meaning and purpose, mentor's enhanced cognition and planned future connections. Relationships were formed between students, people with dementia, and care partners during online visits, an activity that might be implemented outside of a crisis to prevent social isolation across generations. Future efforts to engage people with dementia in residential facilities should be formally integrated into the care plan and staff dedicated to help with technology assigned.

OLDER ADULT'S MARITAL STATUS, SUPPORT EXCHANGES AND PSYCHOLOGICAL WELL-BEING IN EVERYDAY LIFE

Yee To Ng,¹ and Karen Fingerma,² 1. University of Texas at Austin, Austin, Texas, United States, 2. The University of Texas at Austin, Austin, Texas, United States

Social support exchanges are an integral part of older adults' well-being. Yet, we know little about how older adults' marital status may influence their support exchanges with different social partners in everyday life, and whether the effect of support exchanges on daily well-being vary by marital status. Adults aged 65+ ($N = 278$) completed an initial interview about their background and close social networks; then, participants reported whether they provided or received support from their close social partners and rated their psychological well-being for 5 to 6 days. Multilevel logistic models revealed that married older adults were more likely to provide or receive daily support from their close partners than widowed or divorced older adults. However, with respect to specific non-spousal ties, married older adults were less likely to provide support to siblings, friends or others (acquaintances, neighbors) compared to divorced older adults. Although married older adults were more likely to receive support from children than divorced older adults, they were less likely to receive support from siblings and friends compared to widowed or divorced older adults. Furthermore, receiving support from other familial ties (grandchild, other relatives) was associated with reduced daily well-being for widowed older adults whereas married older adults were able to maintain their daily well-being in such situation. Findings highlight the central role siblings and friends play in unmarried older adults' daily support

networks and suggest that receiving support could have differential impact on daily well-being depending on older adults' marital status.

SENSORIMOTOR, COGNITIVE AND AFFECTIVE BARRIERS TO SOCIAL RELATIONS IN AGING: A DYNAMICAL FRAMEWORK

Emmanuelle Tognoli,¹ Alice Wead,² Joseph McKinley,¹ Christopher Beetle,¹ and Christine Williams,¹ 1. Florida Atlantic University, Boca Raton, Florida, United States, 2. Florida Atlantic University, BOCA RATON, Florida, United States

Social interactions of all sorts (e.g. conversing, playing tennis, singing, strolling, etc.) rely on information flows between participants. The process of aging, however, can alter individuals' sensorial, motor, cognitive and affective functioning in ways that may compromise their affinity for social interactions. For instance, hearing deficits or cognitive difficulties associated with word retrieval may contribute to disengagement from conversation and other forms of social interaction, which can lead to social retreat of the affected individuals. Strategies for mitigating such effects must take into account not only individuals' own functional capacities, but also those of their partners in varying social contexts. Indeed, varied social contexts and diversity in partners can offer a beneficial balance of relational effort and comfort. For example, instead of comfortably strolling exclusively with partners of comparable cognitive and motor capabilities, strolling with faster partners can improve social engagement and long-term prospects for a wider range of social interactions. This work reviews an array of possible changes in individual abilities arising from both normal healthy aging and complications due to medical conditions, with an emphasis on their impact on interactions in varying social contexts and diverse groups of social partners. We incorporate theoretical models to explore a wide range of potential mitigation strategies, both for affected individuals and for other members of the social groups surrounding them. Our work focuses on healthy social aging over the long term, which is known to protect physical wellbeing, cognition and brain function.

SOCIAL SUPPORT MODERATES THE IMPACT OF MARITAL TRANSITIONS ON DEPRESSION FOR OLDER ADULT WOMEN

Julia Tucker,¹ Nicholas Bishop,² Kaipeng Wang,³ and Farya Phillips,⁴ 1. University of Texas at Austin, New Braunfels, Texas, United States, 2. Texas State University, San Marcos, Texas, United States, 3. University of Denver, Denver, Colorado, United States, 4. The University of Texas at Austin, Austin, Texas, United States

Given the rapid growth of older Americans and the increased incidence of divorce among this population, it is paramount to identify negative health outcomes following marital transition and investigate the potential protective role of social support. Our study aims to identify relationships between change in depression and marital transitions, test whether social support moderates this association, and to examine variation by gender. The sample included 3,705 participants from the Health and Retirement Study, who reported being married or partnered in 2012. Changes in

marital status were measured between 2012 and 2014 (remained married/partnered (reference), divorced/separated, and widowed). Depression was measured using the Center for Epidemiological Studies Depression short form (CESD-8). Three types of social support from family, friends, and children were assessed: social support, social strain, and social contact. Autoregressive multiple regression was used to examine the relationship between change in depression, marital transitions, social support, and gender. Widowhood and social strain were independently associated with an increase in CESD-8 scores between 2012 and 2014. Significant interactions between social support and social strain, and separation/divorce were identified, and the relationship between social support, depression, and divorce varied by gender. Change in depression was positively associated with social support for separated/divorced females, but not separated/divorced males. These results indicate that social support may modify the influence of divorce on changes in depression among recently divorced older females. These findings can help mental health service providers more effectively target older adults at the greatest risk of depression after experiencing a marital transition.

STRESS-BUFFERING FACTORS OF SOCIAL INTEGRATION ON DEPRESSIVE SYMPTOMS OVER TIME IN LATE-LIFE

Emily Kinkade,¹ and Heather Fuller,² 1. *North Dakota State University, Fargo, North Dakota, United States*, 2. *North Dakota State University, Fargo, North Dakota, United States*

The negative impacts of stress on older adults' well-being are well documented, and social integration is posited as protective against such detrimental effects. Previous research illustrates the stress-buffering effect of social relationships on both physical and mental health, such as depressive symptoms, in older adults. The purpose of this study was to expand on prior findings by investigating the longitudinal stress-buffering effect of various dimensions of social integration on depressive symptoms among an older sample. Four waves of data were drawn from the Social Integration and Aging Study, including 416 older adults (ages 60-100). Subscales of the Social Integration in Later Life Scale measuring frequency and satisfaction with social ties and community interaction were used to assess distinct dimensions of social integration. Multilevel modeling demonstrated that two facets of social integration—satisfaction with social ties and frequency of community interaction—moderated the relationship between perceived stress and trajectories of depressive symptoms over time. Participants who reported high levels of stress reported fewer depressive symptoms if they had high satisfaction with social ties and high frequency of community involvement. Interestingly, frequency of contact with social ties and satisfaction with community interaction did not similarly buffer negative effects for depressive symptoms. These findings indicate the value of remaining actively engaged in the community and maintaining meaningful relationships as older adults age. Future research should investigate programs to foster relationships and engagement between older adults and their communities, with particular consideration of populations at a greater risk for isolation.

THE EFFECT OF INTERPERSONAL RELATIONSHIP AND SOCIAL ACTIVITY ON THE PHYSICAL AND MENTAL HEALTH OF OLDER KOREAN ADULTS

Meeryoung Kim,¹ and Linda Park,² 1. *Daegu University, Daegu, Kyongsang-bukto, Republic of Korea*, 2. *University of Wisconsin-Madison, Madison, Wisconsin, United States*

Maintaining interpersonal relationships and social activities are important as you get older. Activity theory indicates that social activities and human relations are important factors for older adults' physical and mental health. However, the effects between the quantity and quality of interpersonal relationships and social activities will be different. This study compared which of the effects has a greater impact between interpersonal and social activities on physical and mental health. This study used the 6th additional wave (2016) and 7th wave (2017) of the Korean Retirement and Income Study. The subjects of this study were older adults who are aged 65 and older and the sample size was 2,152. Multiple regression was used for data analysis. Demographic variables were controlled. Independent variables were interpersonal relationships, social activities, satisfaction with interpersonal relationships, and satisfaction with social activities. Dependent variables were physical health and mental health, with depressive symptoms used as a proxy for mental health. β s was used to determine the relative influence on dependent variables. Interpersonal relationships, satisfaction with interpersonal relationships, and satisfaction with social activities significantly influenced physical health. Among them, interpersonal satisfaction was found to be the most influential factor on physical health. In addition, interpersonal satisfaction was found to be the most influential factor on mental health than interpersonal relationships. Satisfaction with social activities only affected physical health. The implications of this study were that the quality of interpersonal relationships and social activities of older adults affected physical and mental health more than quantity.

UNDERSTANDING TECHNOLOGY ANXIETY BY THE INTERACTION BETWEEN SOCIAL SUPPORT AND EDUCATIONAL CONTEXT

Susanna Joo,¹ Changmin Lee,² YoonMyung Kim,² Chang Oh Kim,³ Yun Mook Lim,² and Hey Jung Jun,² 1. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 3. *Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The purpose of this study was to examine the interaction effects of social support from family and educational contexts on technology anxiety among Korean older adults. We collected data by online recruiting in February 2021, and the sample was Korean older adults without dementia (N=310; 65-89 years old). The dependent variable was technology anxiety, which meant the expected degree of worry under the assumption that a wearable robot for exercise was used. Independent variables were four types of social support (emotional, instrumental, physical, and financial support) provided by family members, such as spouse, children, or siblings. The moderating

variable was the binary educational context (high school and under=0; college level and over=1). Interaction effects were estimated by bootstrapping and PROCESS macro with four regression models about each type of social support. Results showed the interaction effect between physical support and educational context was significant on technology anxiety. Concretely, getting more physical support was significantly associated with a lower level of technology anxiety for highly educated older adults, while it was not significant for less-educated older adults. There was no additional type of social support which had not only significant interaction effects with educational context but also main effects on technology anxiety. It suggested that providing direct physical help, including daily care or assistance, could decrease feeling technology anxiety, especially not for less-educated seniors but for highly educated Korean older adults.

Session 9465 (Poster)

Spirituality and Religion

CAN WORKING TOGETHER BUFFER DEPRESSION AMONG OLDER, RELIGIOUS AFRICAN AMERICAN COUPLES?

Antonius Skipper,¹ Andrew Rose,² Ethan Jones,² Alex Reeves,¹ and Jhazzmyn Joiner,¹ 1. *Georgia State University, Atlanta, Georgia, United States*, 2. *Texas Tech University, Lubbock, Texas, United States*

Depression is a growing concern among older African Americans, as many within this group hesitate to seek professional help from psychiatrists or counselors. Instead, existing literature notes that older African Americans frequently utilize informal social support networks (e.g., church leaders) to respond to stress and buffer the negative effects of depression and depressive symptoms. Yet, little is known about the shared coping practices of older African American couples in relation to depression. Given the commonly noted high levels of religiosity among African Americans, this study examined communal coping as a mediator between sanctification and depression for older African American couples. This study utilized the dyadic data of 194 (146 married and 48 cohabiting) African American couples between the ages of 50 and 86 years. Capturing data with the Revised Sanctification of Marriage scale, the Communal Coping scale, and the Major Depression Inventory, bias-corrected bootstrap analysis revealed that men's relationship sanctification and women's depression was partially mediated by men's, as well as the sum of men's and women's, communal coping in married couples. Further, men's relationship sanctification and men's depression was partially mediated by men's, as well as the sum of men's and women's, communal coping. In addition, women's sanctification was positively associated with men's depression, directly. These findings are valuable in understanding the complex buffers, and contributors, to depression among older African American couples who may identify closely with religion but prefer the support of a partner over professional care.

CROSS-LEVEL MEDIATING EFFECTS OF SOCIAL RELATIONSHIPS BETWEEN RELIGIOSITY AND SUCCESSFUL AGING

Hayoung Park,¹ Hey Jung Jun,¹ and Susanna Joo,² 1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea*

This study aimed to analyze the cross-level mediating effects of social relationships on the association between religiosity and successful aging. The data was the 7th Korean Longitudinal Study of Ageing and the sample was 1,191 couples aged 65 and above. Independent variables were the level of participation in religious activities at the individual level and religious similarity between couples at the couple level. The dependent variable was successful aging at the individual level, which consisted of physical, cognitive, social, and psychological dimensions. Mediating variables were two social relationships: frequency of social interaction at the individual level and marital satisfaction at the couple level. We applied Full Information Maximum Likelihood estimation to include 8% of the sample with missing values in data. According to the multi-level mediation path analysis, both frequency of social interaction and marital satisfaction had mediating effects on the association between the level of participation in religious activities and successful aging; the more they participate in religious activities, the higher the frequency of social interaction and marital satisfaction, and this had positive effects on successful aging. Also, marital satisfaction had a mediating effect on the association between religious similarity and successful aging; when married couples have the same religion, marital satisfaction was higher than when they do not, and this had a positive effect on successful aging. This study is meaningful in presenting multi-dimensional discussions on religiosity and social relationships in later life and a new empirical model to promote successful aging at both individual and couple levels.

RELATIONAL SANCTITY AS A CONTRIBUTOR TO FORGIVENESS: DYADIC DATA FROM OLDER AFRICAN AMERICAN COUPLES

Antonius Skipper,¹ Andrew Rose,² Alex Reeves,¹ Jhazzmyn Joiner,¹ and Ethan Jones,² 1. *Georgia State University, Atlanta, Georgia, United States*, 2. *Texas Tech University, Lubbock, Texas, United States*

Although research finds that healthy romantic relationships can provide several benefits in older adulthood, few studies examine the relational characteristics of older African American couples. Further, despite positive associations between religiosity and age, particularly among African Americans, a dearth of dyadic data consider the importance of religious constructs within the relationships of older African Americans. To address this gap, this study utilized dyadic data from the Strong African American Couples Project to examine the interconnection between relational sanctity and forgiveness among married and cohabiting older African American couples. A total of 194 African American couples (146 married and 48 cohabiting) aged 50 to 86 years were included in the analysis, and Actor Partner Independence Models were used to test the relational effects of sanctity and forgiveness. Findings revealed that no

significant effects existed when women's relational sanctity was the predictor variable. However, men's relational sanctity had a significant positive association with both his own forgiveness of his partner and his perception of his partner's forgiveness. These findings have valuable implications for professionals engaging older African American couples. First, this study helps to counter the often deficit-focused literature on African American couples by highlighting the potentially stabilizing influence of viewing one's relationship as sacred. Second, this study offers a rare glimpse into the aspects of men's religiosity that may be more consequential than women's. Both practitioners and clergy could use this information to inform counseling efforts that seek to build on the strengths of married and cohabiting older African American couples.

RELIGIOSITY AND PERCEIVED SOCIAL SUPPORT ENHANCE OLDER ADULTS' RESILIENCE AFTER THE 2016 FLOOD

Katie Cherry,¹ Matthew Calamia,² Emily Elliott,² and Angelina Cantelli,² 1. *Louisiana State University, Louisiana State University/Baton Rouge, Louisiana, United States*, 2. *Louisiana State University, Baton Rouge, Louisiana, United States*

In 2016, catastrophic flooding destroyed homes and property across south Louisiana. This study is part of a larger program of research that addresses the role of prior hurricane and flood experiences on current health and well-being in later life. Participants were predominately middle-aged and older adults who varied in current and prior severe weather experiences (M age=49.6 years, age range 18-88 years). All were tested during the immediate aftermath of the 2016 flood (Wave 1; N=223) and most participated in a follow-up assessment 9 (+/- 3) months later (Wave 2; N=202). Cherry et al. (2021) reported that greater flood stressors at Wave 1, such as displacement, flood-related losses, and damage to homes and property, were associated with more symptoms of post-traumatic stress disorder (PTSD). In this study, we tested the hypothesis that age, religiosity, and perceived social support would be positively associated with post-flood resilience at the Wave 2 follow-up. Results indicated that age was positively associated with religiosity and resilience, and negatively correlated with symptoms of PTSD. Additionally, faith community involvement, non-organizational religiosity, and religious beliefs and practices were all significantly correlated with post-flood resilience. Perceived social support was positively associated with resilience, and inversely correlated with PTSD symptoms. These data suggest that religiosity and perceived social support are valuable resources that foster post-disaster resilience among middle aged and older adults. Implications of these data for current views on age-related strengths and vulnerabilities after severe weather events are discussed.

THE IMPACT OF HEALTH LITERACY AND RELIGIOSITY ON ATTITUDES TOWARDS PHYSICIAN-ASSISTED DEATH

Amy Albright,¹ Joshua Tutek,² and Rebecca Allen,³ 1. *VA Maine HCS, Gorham, Maine, United States*, 2. *Stanford University, Stanford University School of Medicine, California, United States*, 3. *University of Alabama, Tuscaloosa, Alabama, United States*

The aim of the current study was to examine the relationship between functional health literacy and religiosity regarding attitudes towards physician-assisted death (PAD). Of participants, the majority were female (62.6%) and non-Hispanic White (79.6%), and ages ranged from 19 to 83 (M = 37.81, SD = 12.55). As measured by the Newest Vital Sign, 82.6% (n = 219) of individuals within the current sample had adequate functional health literacy, while 10.6% (n = 28) scored within the "possibly limited" range, and 6.8% (n = 18) scored within the "highly limited" range. There was a positive association between religiosity and age ($r = .21, p < .001$), and older participants were more likely to endorse religious beliefs and/or activities. There was a significant association between greater acceptance of attitudes towards PAD and functional health literacy ($r = .17, p < .01$), indicating that those with higher health literacy have more positive attitudes towards PAD. There was no significant association between attitudes towards PAD and age ($r = -.02, p > .05$) or education ($r = -.05, p > .05$). Similarly, attitudes did not differ by gender ($t(256) = -.66, p > .05$) or by race/ethnicity, ($F(5, 253) = .73, p > .05$). Of note, functional health literacy may be particularly important to monitor in this context, as several studies (i.e., Kobayashi et al., 2015) have shown that health literacy may decrease with mild cognitive impairment and may therefore provide important information regarding older adults with this condition.

TRANSFORMATIONS AND TRANSMISSION – A CONTEXTUAL LOOK AT RELIGIOUS BIOGRAPHIES OF OLDER ADULTS

Jenni Spannari, Kati Tervo-Niemela, and Laura Kallatsa, *University of Eastern Finland, Joensuu, Pohjois-Karjala, Finland*

Examination of religious biographies tend to show increase of religiosity towards old age, most often in the context of a previously familiar religious community. These changes in individuals do not happen in a vacuum. Religious landscapes are also in transformation, characterized by a steady decline of institutional religiosity and religious practice in most European countries and more recently in the US and Canada, too. However, there is a dire lack of detailed knowledge on how these changes in individuals and societies are intertwined. This paper presents findings of the Finnish sub-project of the five-country research project "Transmission of religion across generations." The paper utilizes both three-generation interviews, and the contextual information gathered in the families about the past and present generations. The narratives about religious biographies of the oldest (gen.1) interviewees are discussed, and set in the context of the changes in the surrounding social sphere and the interviewees' role in the family. Key findings include a general trend of increased flexibility, openness and communication over time – both in the religious views of the individuals, the roles different generations take in the family, and the cultural atmosphere in the society. Also, the results suggest that this flexibility is an essential factor in successful transmission of religion or other convictions across generations. The findings illustrate the complexity and contextuality of building and researching narratives of religious biographies. Thus, the results contribute to future examinations on how changes in

societies and families affect the religious styles and convictions of older adults.

Session 9470 (Poster)

Technology, Social Support, and Connectedness

COMMUNITY COLLABORATIONS & TECHNOLOGY SUCCESSFULLY CONNECT ISOLATED OLDER ADULTS TO EDUCATION & ACTIVITIES

Laura Spradley, *UAMS Arkansas Geriatric Education Collaborative (AGEC), Little Rock, Arkansas, United States*

Providing programs, activities and education to older adults (OA) is a challenge under normal circumstances. The Arkansas Geriatric Education Collaborative (AGEC) is a HRSA Geriatric Workforce Enhancement Program with a mission to “provide high quality programs that support healthy aging in Arkansas.” Prior to the pandemic, AGEC educators provided face-to-face programs to OA’s through senior centers, places of worship and other public venues. The pandemic changed all that. In-person programs were replaced with zoom presentations, social media events and pre-recorded programs placed on websites and patient-learn platforms for 24/7 viewing. Gaining viewership proved difficult and after collaborative research, it was determined the major barrier was a digital divide between access, usage and knowledge of digital platforms. To overcome this barrier, AGEC utilized TV, radio, libraries, digital infographics, newsletters and video tips addressing Wi-Fi and technology training. Videos, distributed via multiple routes, addressed basic topics such as “Creating and Utilizing Zoom and Facebook accounts” and “how to improve telehealth visits”. After establishment of a regular audience, AGEC engaged new and established partners and hosted a plethora of educational programs and activities further expanding the viewing audiences. In addition, with personalized emails and targeted marketing, AGEC engaged OA audiences in caregiving workshops, on-line caregiver support groups, telephone check-ins and exercise programs. Many OAs have found ways to bridge the digital divide and are engaged and active with educational and program activities and have used their new skills to connect with other OAs, grandkids, friends and even their spiritual communities.

EFFECT OF THE SARS-COV-2 PANDEMIC ON TECHNOLOGY USE: IN-PERSON VERSUS VIDEO-CHAT COMMUNICATION

Sarah Hubner,¹ Alex Swanson,² Akankshya Chataut,¹ Stephen Kotopka,³ Natalie Manley,³ Marcia Shade,³ and Julie Blaskewicz Boron,¹ *1. University of Nebraska Omaha, Omaha, Nebraska, United States, 2. University of Nebraska at Omaha, Omaha, Nebraska, United States, 3. University of Nebraska Medical Center, Omaha, Nebraska, United States*

COVID-19 risk-reduction efforts have protected high-risk individuals (including older adults) but have significantly altered life; persons now face reduced socialization. Advancing technologies (e.g., video-chat) may be useful in alleviating consequences of risk-reduction efforts, including loneliness, by improving access to alternative connection/communication across the lifespan. The purpose of this study was to

investigate the relationships between technology use and individuals as this may contribute to well-being among older adults during COVID-19 and future isolating events. Participants (N=652) aged 19+ completed a questionnaire via Amazon Mechanical Turk; demographic, socialization, and technology-use data were collected. Respondents (MAge=45.15±15.81) were generally male (50.1%) and white (77.3%). In-person communication and video-chat were analyzed descriptively and with binary regressions. Results of a Wilcoxon Signed-Ranks Test indicated that video-chat (mean rank=228.45) was reported at higher frequency of use versus in-person conversations (mean-rank=202.48), $Z=-4.8, p<.001$. Additionally, being female positively predicted use of video chat ($B=0.42, p<.05$) while increasing age negatively predicted use ($B=-0.01, p<.05$). Regression results suggest that populations reporting higher video-chat communication (e.g., females, younger adults) may be motivated by maintaining social connectedness despite distancing and/or are committed to healthy behaviors, increasing aversion to in-person experiences. In contrast, it may be that persons reporting low video-chat use (e.g., males, older adults) may be less interested in distanced communication or may have lower technology comfort/access. Notably, sampling bias may influence results as data was collected online; future investigation is warranted. Ultimately, understanding interest in and barriers to using technology is vital to developing systems/services which support connection/communication when in-person contact is limited.

INVESTIGATION OF COMMUNICATION TYPE AND INDIVIDUAL CHARACTERISTICS : A LONGITUDINAL HRS ANALYSIS

Kaleena Odd, Sarah Hubner, Hyeon Jung Kim, and Julie Blaskewicz Boron, *University of Nebraska Omaha, Omaha, Nebraska, United States*

Older adults are at increased risk for loneliness/isolation, particularly with new COVID-19 recommendations; however, communication may help mitigate these negative perceptions. Reductions in loneliness/isolation may also significantly improve quality of life and well-being for vulnerable populations. Thus, the purpose of this study was to investigate the relationships between communication, individual characteristics, and time, to provide a clearer understanding of communication patterns in a longitudinal cohort. Participants (N=2351) with no missing data on any variables of interest (across time-points) were pulled from the Health and Retirement Study’s Consumption and Activity’s Mail Survey (waves collected: 2013, 2015, 2017). When last reported (2016/17), respondents were an average age of 70.14(SD=9.9), were generally female (63.0%) and white (75.7%). Analyses included longitudinal investigation, normality tests, and regression. Assumptions were violated in ANOVA; results of a Kruskal-Wallis test revealed that there were no significant changes in the distribution of in-person or distanced communication across the three waves. Individual responses were then averaged and standardized across waves (per participant for each outcome variable). In-person communication regression results reveal that being female positively predicted in-person conversation volume ($B=0.23, p<.001$) as did increasing number of years in school ($B=0.03, p<.001$), while being non-white negatively

predicted in-person conversation ($B=-0.301, p<.001$). Distanced communication regression results reveal being female positively predicted volume of distanced communication ($B=0.381, p<.001$); however, being non-white and younger positively predicted increased volume of distanced communication ($B=0.241, p<.001$; $B=0.005, p<.001$, respectively). Given the varied communication patterns, future research should consider explanatory mechanisms in addition to investigating changes as a result of the ongoing pandemic.

SOCIAL MEDIA USE AND EMOTIONAL WELL-BEING: THE ROLE OF PHYSICAL ACTIVITY

Xin Yao Lin,¹ and Margie Lachman,² 1. *Brandeis University, Waltham, Massachusetts, United States*, 2. *Brandeis University, Brandeis University, Massachusetts, United States*

There are mixed findings as to whether social media use (SMU) is positively or negatively related to well-being (positive/negative affect), and this relationship varies by age. The current study seeks to further explore this relationship by examining physical activity (PA) as a potential mediator at both a within (intraindividual) and between-person (interindividual) level across adulthood. The data are from the Midlife in the United States Refresher eight-day daily diary study ($N=782$, ages 25-75) with self-reported frequency of SMU, PA, and well-being (positive/negative affect). Multilevel structural equation modeling simultaneously tested how the relationships between the variables differed at both the between- and within-person levels. Between-person results showed that across the week, those who reported less SMU reported engaging in more PA, and more PA was associated with more positive affect. PA significantly mediated the relationship between SMU and positive affect for midlife and older adults, but not for younger adults. Effects for negative affect were not significant. Within-person results indicated that days with more PA were associated with more positive affect; however, PA did not mediate the relationship between SMU and positive or negative affect. These findings suggest the benefits of engaging in PA on one's positive emotional well-being at both the between- and within-person levels. However, for midlife and older adults, more SMU across the week may take away time from engaging in PA, which in turn lowers their positive affect. Implications of the effects of SMU on PA and well-being across adulthood are discussed.

TECHNOLOGY AND SOCIAL ISOLATION, LONELINESS, AND HEALTH INEQUITIES AMONG OLDER ADULTS

Jeffrey Jutai, and Joshua Tuazon, *University of Ottawa, Ottawa, Ontario, Canada*

Because of the COVID-19 pandemic, older adults have been advised to stay-at-home to reduce the risk of infection. Social distancing and quarantine measures increase their vulnerability to adverse health outcomes like depression and cardiovascular disease. Technology is an effective tool to promote social connectedness among older adults affected by the pandemic; however, its role in reducing loneliness and health inequities is not well understood. The goal of this project was to construct a model for how technologies may be deployed to mitigate the impact of a pandemic on social isolation, loneliness, and health inequities for older adults. PubMed,

SCOPUS, and PsychINFO were searched for the following keywords: "social isolation," "loneliness," "social support," "resilience," "technology," "pandemic," and "health inequities." Articles selected for full analysis attempted to understand or observe how technology alleviates social isolation and/or loneliness among older adults. Research evidence indicates that using technology reduces loneliness directly and indirectly (by reducing social isolation) and can strengthen social support, which in turn promotes resilience among older adults. Video-based technologies encourage care-seeking behaviors in this population. There is insufficient evidence to determine technology's relationship to health inequities experienced by older adults. The model we have proposed should help advance research on the relationship between technology and health inequities among older adults that may be aggravated by pandemic-like situations. We hypothesize that technology interventions for social support and functional competence should be sequenced in order to have the best effects on reducing health disparities.

THE ASSOCIATION BETWEEN SOCIAL SUPPORT AND ATTITUDE TOWARD TECHNOLOGY DIFFERS BY EDUCATIONAL LEVEL

Susanna Joo,¹ Changmin Lee,² Kwang Joon Kim,³ DaeEun Kim,² and Hey Jung Jun,² 1. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 3. *Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The present study aimed to examine the moderating effects of the educational context on the association between social support from family members and attitude toward using gerontechnology among Korean older adults. The sample was Korean older adults without dementia ($N=310$, Age: 65-89, $M=70.18$, $SD=4.58$). Data were collected by online recruiting in February 2021. The dependent variable was the attitude toward using gerontechnology, especially, an exoskeleton robot for exercise. Independent variables were four types of social support (emotional, instrumental, physical, and financial support) from family members. Moderating variable was the binary educational group (high school and below, or college and over). We analyzed four regression models including each interaction term between education and a type of social support using PROCESS macro and bootstrapping. Results showed educational context had a single significant moderating effect on the association between emotional support and attitude toward using gerontechnology. Specifically, emotional support had a significant effect on having a positive attitude toward using gerontechnology among older adults who graduated high school or were less educated. However, it was not significant among older adults who were highly educated. Moreover, other types of social support did not have significant main effects as well as interaction effects with education on the attitude toward using gerontechnology. Findings of the present study implied emotional support from family members, such as spouse, children, or siblings, was useful to enhance having a positive attitude toward using new technology, especially for older adults who did not experience college-level educational context.

THE ASSOCIATION BETWEEN SPOUSAL SUPPORT AND ATTITUDE FOR GERONTECHNOLOGY VIA FACILITATING CONDITIONS

Susanna Joo,¹ Seong Hee Kim,² Changmin Lee,³ Kwang Joon Kim,⁴ DaeEun Kim,³ YoonMyung Kim,³ and Hey Jung Jun,³ 1. *Yonsei University, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Sungkyunkwan University, Seoul, Republic of Korea*, 3. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 4. *Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

This study examined the mediating effects of facilitating conditions (FC) on the association between types of social support providers and attitude toward using gerontechnology (AUG) or between types of social support and AUG. The sample was 256 older Koreans having a partner and children (N=256; 66-88 years old; M=69.91; SD=4.19). The dependent variable was AUG in terms of an exoskeleton robot for exercise. There were two kinds of independent variables: 1) four types of social support provider (spouse, children, siblings/relatives, and friends/neighbors), and 2) four types of social support (emotional, instrumental, physical, and financial support). Mediating variable was calculated as the mean of FC from five questions. There were two analytic steps: 1) structural equation modeling with four latent variables about types of social support provider, and 2) path analysis with four types of social support if only for significant providers at the first analysis. The results from the first step of analysis showed that only social support from spouses had a significant effect on AUG via FC to use gerontechnology. In the second step of analysis, emotional support from spouses was associated with the higher level of AUG via FC to use gerontechnology. The findings could shed light on the salience of emotional support from spouses in terms of the positive attitude on technology usage in later life through enhancing FC for technology acceptance.

THE ASSOCIATION BETWEEN THE TYPES OF EXERCISE MOTIVATION AND SOCIAL PRESENCE ABOUT GERONTECHNOLOGY

Si Young Song,¹ Inhye Jung,¹ Miseon Kang,¹ Kwang Joon Kim,² DaeEun Kim,¹ and Hey Jung Jun,¹ 1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Severance Hospital, Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The purpose of this study was to identify the types of exercise motivation and examine the association between the types of exercise motivation and social presence about exercise-related gerontechnology among Korean young-olds. In this study, social presence about gerontechnology implies the degree of perception of a robot that helps exercise functions as human-like socially interacting entities (Heerink, 2010). Online survey data collected from the Korean older adults over the age of 65 in February 2021 was used, and the subjects of this study were 154 young-olds aged 65 to 74 who exercise regularly. Latent class analysis (LCA) was conducted to classify the types of exercise motivation, followed by multiple regression analysis. As a result of LCA, the types of exercise motivation was classified with two groups. These groups were named 'for pleasure and leisure (PL, 77.2%)' and 'for maintenance of health (MH, 22.8%)', respectively. The result

of multiple regression showed that compared to the second group (MH), the social presence about gerontechnology was high for the first group (PL) after controlling age, gender, education level, marital status, household income and chronic disease. These results indicate the Korean young-olds' exercise motivation may vary and expectations for social presence toward exercise-related gerontechnology differ depending on the exercise motivation. To date, the importance of social presence in gerontechnology has tended to be emphasized mainly in the care field. This study suggests that exercise-related gerontechnology devices also need to consider the aspect of social presence especially for young-olds who exercise for pleasure and leisure.

THE EFFECTIVENESS OF AN INTERGENERATIONAL TECHNOLOGY PROGRAM FOR OLDER ADULTS: A PILOT STUDY

Dolapo Adeniji,¹ Margaret Adamek,² and Sally Catlin,³ 1. *IUPUI, Avon, Indiana, United States*, 2. *Indiana University, INDIANAPOLIS, Indiana, United States*, 3. *Indiana University IUPUI, Indianapolis, Indiana, United States*

While an increasing number of services and opportunities are available through technology devices such as smartphones and iPad, older adults often lack the technology skills and know-how to access such services. The use of social media, email, and texting can also lessen social isolation of older adults. In this project, nine undergraduate Computer Information Technology students enrolled in a service-learning course served as mentors for older adults. A total of 33 older adults (MAge= 77.9 SDAge= 8.62) participated in a 14 weeks intergenerational technology education at two community senior centers in an urban Midwest city. Fourteen participants completed both pre- and post-surveys. Significant improvement was found between pre- and post-surveys outcomes in technology anxiety and social engagement of the older adults. Findings from our qualitative data revealed that intergenerational program enables older adult to benefit from individual and group learning, make new friends among peers, experience intergenerational interactions, and have confidence in technology use. However, the intergenerational technology program helped to decrease technology anxiety and improve the participants' social engagement. Engaging technology students in mentoring older adults in small group at a community center proved to be mutually beneficial to both the students and the older adults. The program boosted older adults' comfort with technology use as well as encouraging social engagement with peers, mentors, and the virtual world.

UNDERSTANDING RACIAL AND RURAL DISPARITIES IN THE RELATIONSHIP BETWEEN SOCIAL ISOLATION AND SOCIAL TECHNOLOGY USE

Kaileigh Byrne, Reza Ghaiumy Anaraky, Hannah Barfield, and Summerlin Nickel, *Clemson University, Clemson, South Carolina, United States*

Social isolation is characterized by lack of social contacts and high degrees of loneliness. Feelings of loneliness and social isolation are linked to declines in cognitive functioning and increased risk of dementia. Previous research suggests that loneliness is more prevalent among Black and rural older adults compared to White and urban-dwelling older

adults. Given these disparities, it is important to identify methods that reduce social isolation and loneliness among this population. Social technology, such as Facebook and Skype, is one possible way to connect with others. This study uses the Health and Retirement Study (HRS) dataset to examine racial and rural disparities in the relationship between social technology use and social isolation, loneliness, and social support among individuals age 50 and older. The overarching hypotheses are that (1) rural-dwelling older adults and older Blacks will report less social technology use compared to urban-dwelling and older White adults, and (2) there will be a negative relationship between loneliness and social technology use, and (3) a positive relationship between perceived positive social support and social technology use. Racial or rural disparities in these latter potential relationships are exploratory. Multiple linear regression analysis will be performed to assess these relationships. Preliminary correlational results indicate that, consistent with prior work, greater use of social technology was associated with higher social support ($N=6,029$; $r=.29$, $p<.001$). However, contrary to our hypothesis, greater self-reported loneliness was associated with greater social technology ($r=.09$, $p<.001$). Examination of potential racial and rural disparities in these relationships are currently underway.

Session 9500 (Late Breaking Poster)

Late Breaking Poster Session I

A DIGITAL INTERVENTION TO ALLEVIATE LONELINESS AND DEPRESSION AMONG OLDER PERSONS DURING THE COVID-19 OUTBREAK

Ella Cohn-Schwartz,¹ Stav Shapira,² Daphna Yeshua-Katz,³ Limor Aharonson-Daniel,⁴ A. Mark Clarfield,³ and Orly Sarid,³ 1. *Ben-Gurion University, Beer-Sheva, HaDarom, Israel*, 2. *Ben-Gurion University of the Negev, Ben-Gurion University of the Negev, HaDarom, Israel*, 3. *Ben-Gurion University of the Negev, Beer Sheva, HaDarom, Israel*, 4. *Ben-Gurion University of the Negev, Beer Shave, HaDarom, Israel*

Social distancing has been proven to be effective in reducing infections but may cause ill effects on the mental health of older adults. We evaluated the effects of a short-term virtual group intervention that provided tools to promote better coping, and mitigate adverse mental health effects during the outbreak of the covid-19 pandemic. A Randomized controlled trial tested the effects of a guided intervention comprised of seven online group sessions in which cognitive-behavioral techniques targeting maladaptive beliefs and appraisals were learned and practiced via ZOOM. A total of 82 community-dwelling adults from Israel, aged between 65 - 90 were randomized to either an intervention group ($n=64$) or a wait-list control group ($n=18$). Loneliness (UCLA loneliness scale) and depressive symptoms (PHQ-9) were measured pre-intervention, post-intervention, and at 1-month follow-up. The findings showed a significant decrease in loneliness and depression scores in the intervention group with results maintained at 1-month follow-up. There were no significant changes in the wait-list control group. In addition, ten participants (16%) from the intervention group

demonstrated a clinically meaningful decrease in depression between baseline and post-intervention, and this was maintained among 7 participants (10%) at 1-month follow-up, compared to only 1 participant (5%) in the control group. Our intervention presents a simple and easy-to-implement tool. Its relevance extends beyond the current pandemic as the skills acquired can be applied in other forms of social crises and during routine life, in order to promote the mental health of older adults who live alone and/or reside in remote areas.

A FAT-PROMOTING PLANT EXTRACT FROM ARTEMISIA SCOPARIA EXERTS GEROPROTECTIVE EFFECTS ON C. ELEGANS HEALTH & LIFESPAN

Bhaswati Ghosh, Hayden Guidry, Maxwell Johnston, and Adam Bohnert, *Louisiana State University, BATON ROUGE, Louisiana, United States*

Like other biological processes, aging is not random, but subject to molecular control. Natural products that act on conserved metabolic pathways may provide entry points to extend animal lifespan and promote healthy aging. Here, we show that a botanical extract from *Artemisia scoparia* (SCO), which promotes fat storage and metabolic resiliency in mice, exerts pro-longevity effects on the nematode *Caenorhabditis elegans*, even when administered in mid-adulthood. SCO-treated worms exhibit significantly higher levels of fat compared to controls but live up to 40% longer, with signs of improved stress resistance in late age. Molecularly, SCO links elevated fat to enhanced longevity and stress resistance via activation of the transcription factor DAF-16/FOXO and upregulation of DAF-16-targeted $\Delta 9$ desaturases, lifespan-extending metabolic enzymes that oversee the biosynthesis of monounsaturated fatty acids. These findings identify SCO as a natural product that can modify fat regulation for longevity benefit and add to growing evidence indicating that elevated fat can be pro-longevity in some circumstances.

A META-ANALYSIS OF THE EFFECTS OF TAILOR ACTIVITY PROGRAM (TAP) FOR PEOPLE WITH DEMENTIA

Jiin Jeong,¹ Eun-Young Yoo,² Byoung-Ho Kang,¹ and Yae-Na Ha,¹ 1. *Graduate school, Yonsei University, Republic of Korea, Kangwon-do, Republic of Korea*, 2. *College of Software and Digital Healthcare Convergence, Yonsei University, Republic of Korea, Kangwon-do, Republic of Korea*

Ninety eight percent of people with dementia are accompanied by neuropsychiatric symptoms (NPS). NPS is an important predictor of the negative prognosis of dementia. It also increases the burden on caregivers and lowers the quality of life. The tailored activity program (TAP), which is occupation-based intervention, have a positive effect on reducing NPS through meaningful activities. The aim of this study was to provide an integrated effectiveness of the TAP on NPS in people with dementia and caregiver burden through meta-analysis. We searched for studies that indicated the effectiveness of TAP through Embase, ProQuest, Pubmed, and RISS. We included a total of seven TAP studies written in Korean and English. Of these seven study designs, five were randomized control trials (RCTs) and two were

one group non-RCTs. The result of meta-analysis shows that the effect size of the NPS was 0.62 (95% confidence interval [CI]=0.40-0.83, $p < 0.001$), the caregiver burden was 0.68 (95% CI=0.29-1.07, $p = 0.001$). Both variables indicated moderate effect. These results indicate that the TAP is an effective intervention for reducing NPS of people with dementia and the burden of caregivers. Therefore, TAP is clinically useful approach, we expect TAP to be actively applied to people with dementia in the community.

ACTION PLANNING CHECKLIST FOR SOCIAL DETERMINANTS OF HEALTH: OLDER ADULTS WITH CHRONIC CONDITIONS

Joan Ilardo, and Angela Zell, *Michigan State University College of Human Medicine, East Lansing, Michigan, United States*

Medical residents need training to assess social determinants of health (SDOH) related to chronic conditions. We created a checklist to identify SDOH affecting residency clinic patients' ability to manage chronic conditions. The tool: 1) involves resident training; 2) provides decision support checklist; 3) influences patient activation; and 4) increases provider and patient communication through shared decision making. Action Planning Guide checklist (APG) includes questions pertaining to SDOH preventing patients from managing their chronic conditions and actions patients will take. Areas identified are discussed between patient and resident, increasing patient activation. The clinic's nurse care facilitator guides referrals to community-based resources. Fifty-two patients were enrolled, with 75% of patients responding they would like to be better managers of their chronic conditions. This information is used to develop patient's goals of care. Over 90% of patients said their conditions affect their lives and discussed ways better to care for themselves. Over 80% discussed medication management, health goals to improve their quality of life, and made a plan that maps out ways to reach their goals. All of these are essential for achieving positive health outcomes for older patients with chronic conditions. These attributes promote effective patient/provider partnerships. Seventy referrals were made; food through 2-1-1 (47%); monthly commodity food program (30%); utility payments (11%), and transportation (9%). Twenty-seven referrals were made to agencies serving older adults; 25 to the local AAA information and assistance services, and 2 to Senior Project Fresh Voucher Program.

ADDRESSING PHYSICAL, FUNCTIONAL, AND PHYSIOLOGICAL OUTCOMES IN OLDER ADULTS VIA INTEGRATED MHEALTH INTERVENTION

Melba Hernandez-Tejada,¹ Sundaravadivel Balasubramanian,² John Bian,² Mohan Madiseti,² Alexis Nagel,² Samantha Bernstein,² and Teresa Kelechi,² *1. University of Texas HSC at Houston, Houston, Texas, United States, 2. Medical University of South Carolina, Charleston, South Carolina, United States*

Objective: We evaluated components of an integrated mobile (m)Health-based intervention "Activate for Life" (AFL) on health outcomes in lower-income older adults (65 years and older). **Method:** AFL incorporates balance (Otago; OG), physical strength (Gentle Yoga and Yogic Breathing; GYYB), and mental engagement (Behavioral Activation;

BA) components. Thirty participants were randomly allocated to one of three Arms (n=10 per each arm): OG (Arm 1), (OG+GYYB (Arm2), or OG+GYYB+BA (Arm 3, or full AFL). Groups were evaluated for physical, functional and physiological endpoints at baseline, and posttreatment (12-weeks and/or 3-month follow up). **Results:** Improvements over time in pain interference and 1,5 Ag biomarker were noted for all groups. No significant changes were observed in other physical, functional and physiological measures. **Discussion** This study illustrated potential benefits of the AFL intervention on the health of lower-income older adults and lessons learned from this pilot will be used to make improvements for a large-scale randomized controlled trial.

ADVANCE CARE PLANNING AND HOSPICE USE AMONG PEOPLE WITH DEMENTIA: A REPORT FROM THE HEALTH AND RETIREMENT SURVEY

Kathryn Coccia, *Saint Louis University, St. Louis, Missouri, United States*

People with Alzheimer's disease and related dementias (ADRD) frequently receive sub-optimal end-of-life care (EOLC), often enduring invasive procedures such as tube feeding, resuscitation, and surgery within days of their death. While advance care planning (ACP) has shown effectiveness in improving EOLC for those with ADRD, there are many barriers to ACP specific to the ADRD population. Research suggests that hospice care is optimal in reducing end of life suffering for ADRD patients. This study aimed to empirically assess hospice utilization and ACP for individuals with ADRD compared to individuals without ADRD, and to assess the impact of ACP on hospice utilization for individuals with ADRD. Data came from the 2016-2018 wave of the Health and Retirement Study (HRS), a national longitudinal study collecting health and demographic data on older Americans. This analysis evaluated survey responses from 1,224 proxy respondents for individuals who died during this period. In this sample, people with ADRD were both significantly more likely to have utilized hospice care (OR=1.37) and to have written EOLC instructions in place (OR=1.19). Those with ADRD were 22% less likely to have discussed their EOLC wishes with their proxy than those without ADRD. Having a written EOLC plan in place significantly increased the odds of hospice utilization (OR=1.37) but discussion around EOLC preferences increased odds of hospice utilization at a higher rate (OR=1.59). These results support policy to advance earlier ACP conversations around EOLC preferences and the implementation of written EOLC instructions to reduce suffering for individuals with ADRD diagnoses .

AN ENVIRONMENTAL CONTRIBUTOR TO PARKINSON'S DISEASE CAUSES A HORMETIC LIFESPAN EFFECT IN C. ELEGANS

Jennifer Thies, Hanna Kim, Guy A. Caldwell, and Kim A. Caldwell, *The University of Alabama, Tuscaloosa, Alabama, United States*

Only 5-10% of Parkinson's Disease (PD) cases have a direct genetic origin; however, exposure to herbicides, pesticides, and interactions with soil are potential risk factors. PD is characterized by the loss of dopaminergic (DA) neurons and the formation of protein inclusions that contain α -synuclein (α -syn). Conversely, a soil bacterium,

Streptomyces venezuelae (*S. ven*), produces a secondary metabolite that causes age- and dose- dependent DA neurodegeneration in *C. elegans*; it also exacerbates α -syn-induced DA neurodegeneration. Previous studies from our lab determined that exposure to the *S. ven* metabolite caused oxidative stress, mitochondrial fragmentation and enhanced reactive oxygen species (ROS). Here we report that exposure to *S. ven* metabolite causes a hormetic effect on *C. elegans* lifespan, where low concentrations (5X) extend lifespan in N2 animals, but at higher concentrations (20X) lifespan is decreased. To further examine this hormetic response, we examined *daf-16* mutants in this assay. *daf-16* mutants displayed no significant differences between solvent and metabolite at both high and low concentrations, suggesting the hormetic response is *daf-16* dependent. We also studied *S. ven* metabolite on *C. elegans* aging mutants. We investigated mutants in the AMPK signaling pathway and found when exposed to the 20X concentration of *S. ven* metabolite, *aak-2* mutants displayed no significant difference between solvent and metabolite over lifespan. However, when *aak-2* mutants were exposed to solvent control and the 5X concentration, mutants displayed a decreased lifespan. This suggests that functional *aak-2* might be important for increased lifespan when combating toxicants following chronic exposure.

ARE LONELINESS AND SOCIAL ISOLATION EQUAL THREATS TO HEALTH AND WELL-BEING? AN OUTCOME WIDE LONGITUDINAL APPROACH

Tatiana Henriksson,¹ Julia Nakamura,² and Eric Kim,¹
 1. *University of British Columbia, Vancouver, British Columbia, Canada*, 2. *University of British Columbia, University of British Columbia/Vancouver, British Columbia, Canada*

The detrimental effects of loneliness and social isolation on health and well-being outcomes are well documented. In response, governments, corporations, and community-based organizations have begun leveraging emerging tools to create interventions and policies aimed at reducing loneliness and social isolation at-scale. However, these efforts are frequently hampered by a key knowledge gap: when attempting to alleviate specific health and well-being outcomes, decision-makers are unsure whether to target loneliness, social isolation, or both. Participants (N=13,752) were from the Health and Retirement Study- a diverse nationally representative, and longitudinal sample of U.S. adults aged > 50 years. We examined how changes in loneliness and social isolation over a 4-year follow-up period (from t0:2008/2010 to t1:2012/2014) were associated with 32 indicators of physical-, behavioral-, and psychosocial-health outcomes 4-years later (t2:2016/2018). We used, multiple logistic-, linear-, and generalized-linear regression models, and adjusted for sociodemographics, personality traits, pre-baseline levels of both exposures (loneliness and social isolation), and all outcomes (t0:2008/2010). After adjusting for a wide range of covariates, we observed that both loneliness and social isolation have similar effects on physical health outcomes and health behaviors, whereas loneliness is a stronger predictor of psychological outcomes. In particular, behavioral dimensions of the social isolation measure (i.e., participation in social/religious activities, social interaction frequency) were most strongly associated with the largest number of health

and well-being outcomes, including all-cause mortality. Loneliness and social isolation have independent effects on various health and well-being outcomes, thus, should be distinct targets for interventions aimed at improving the health and well-being.

ARE SUBACUTE CARE PATIENTS LIVING LONGER?

Nidhi Kejriwal,¹ Samantha Tello,² Brooke Davis,³ Mira Kubba,⁴ David Evans,³ Norma Gonzales,⁵ and J. Robert Evans,⁶
 1. *University of California Los Angeles, Redlands, California, United States*, 2. *Western University of Health Sciences, Western University of Health Sciences, California, United States*, 3. *Brigham Young University, Brigham Young University, Utah, United States*, 4. *University of San Diego, University of San Diego, California, United States*, 5. *Community Hospital of San Bernardino, Community Hospital of San Bernardino, California, United States*, 6. *Community Hospital of San Bernardino, evansgi, California, United States*

In order to provide prognostic information for gerontologists who regularly counsel families, we determined to measure the longevity of subacute patients who have feeding tubes and tracheostomies. This study compares two cohorts of patients: 2002-2006 and 2015-2019. T-tests were performed to compare the total days in acute care, the total survival days, and the number of hospital admissions between the two groups. Results revealed (2002-2006, 2015-2019), some variance in the acute care days between the two groups (M= 15.4186, 21.49438) and $p = .66$. There is a wide difference in the total survival days between the two groups with individuals from 2015-2019 living longer than 2002-2006 (M= 229.8198, 644.0449), $p < .001$. However, there is no statistically significant difference in the number of hospital admissions between the two groups (M= 0.994186, 0.7752809), $p = .09754$. We hypothesize that advances in technology, medicine, and care over the span of 17 years contribute to increased longevity. On average, patients in the 2015-2019 group survived 414 days longer than the first group. Yet, even with such advances, more days were spent in acute care in the second group (2015-2019). Our data show subacute longevity has nearly tripled in the last decade. Although patients are living longer, they are often in a vegetative state; in most instances, there is no apparent improvement in quality of life. This study provides current data which will help gerontologists improve prognostication and allow them to form a more realistic long view of care.

ASSOCIATION BETWEEN ANTICHOLINERGIC BURDEN AND DEMENTIA IN UK BIOBANK

Jure Mur, Simon Cox, Riccardo Marioni, Tom Russ, and Graciela Muniz-Terrera, *University of Edinburgh, Edinburgh, Scotland, United Kingdom*

Previous studies on the association between the long-term use of anticholinergic drugs and dementia report heterogeneous results. This variability could be due to, among other factors, different anticholinergic scales used, and differential effects of distinct classes of anticholinergic drugs. Here, we use 171,775 participants of UK Biobank with linked GP prescription records to calculate the cumulative annual anticholinergic burden (ACB) and ascertain dementia diagnoses through GP- and inpatient records. We then use Cox proportional hazards

models to compare 13 anticholinergic scales and anticholinergic burden (ACB) due to different classes of drugs in their association with dementia. We find dementia to be more strongly predicted by ACB than by polypharmacy across most anticholinergic scales (standardised ORs range: 1.027-1.125). Furthermore, not only the baseline ACB, but the slope of the longitudinal trajectory of ACB (HR=1.094; 95% CI: 1.068-1.119) is predictive of dementia. However, the association between ACB and dementia holds only for some classes of drugs – especially antidepressants, antiepileptics, and high-ceiling antidiuretics. Moreover, we do not find a clear relationship between reported anticholinergic potency and dementia risk. The heterogeneity in findings on the association between ACB and dementia may in part be due to different effects for different classes of drugs. Future studies should establish such differences in more detail and further examine the practicality of using a general measure of anticholinergic potency as it relates to the risk of dementia.

ASSOCIATION OF SHOULDER DYSFUNCTION WITH MOBILITY LIMITATION IN OLDER ADULTS OF THE BLSA

Derik Davis,¹ Kai Sun,² Laurence Magder,² and Eleanor Simonsick,³ 1. *University of Maryland School of Medicine, Ellicott City, Maryland, United States*, 2. *University of Maryland School of Medicine, Baltimore, Maryland, United States*, 3. *National Institute on Aging/NIH, Baltimore, Maryland, United States*

Mobility limitation affects one-third of older adults; yet, the impact of shoulder dysfunction which effects roughly 20%, is inadequately documented. As arm swing is a fundamental component of ambulation, we investigated the cross-sectional association between shoulder range of motion (ROM) and walking endurance using time to walk 400m as quickly as possible and lower extremity performance using the expanded Short Physical Performance Battery (e-SPPB). Data are from 614 men (50.5%) and women aged ≥ 60 years (mean 71.8 \pm 8 years) in the Baltimore Longitudinal Study of Aging (BLSA) who performed bilateral shoulder elevation and/or bilateral shoulder external rotation (ER) during nurse-administered physical examination. We examined odds of poor 400m-walk and e-SPPB performance defined as the worst quartile associated with abnormal shoulder elevation ($\leq 9\%$) relative to bilateral normal shoulder elevation and abnormal shoulder external rotation ($\leq 5\%$) relative to bilateral normal shoulder external rotation (ER) in separate analyses. Analyses were adjusted for age, sex, weight and height. Adjusted odds (95% confidence interval) of poor 400m-walk performance associated with abnormal shoulder elevation (N=254) were 4.7 (1.1-19.5; $p=0.035$) and with abnormal shoulder ER (n=401) were 4.8 (1.4-16.7; $p=0.010$). Adjusted odds of poor e-SPPB performance associated with abnormal shoulder elevation (N=462) were 3.5 (1.6-7.7; $p=0.002$) and with abnormal shoulder ER (n=457) were 2.9 (1.1-7.4; $p=0.030$). Results suggest abnormal shoulder ROM is associated with poorer walking endurance capacity and lower-extremity functional performance in the relatively healthy older adults. Future research is warranted to develop novel screening paradigms that mitigate mobility limitation and functional decline in older adults with shoulder dysfunction.

BRAIN CELLULAR SENESCENCE IN MOUSE MODELS OF ALZHEIMER'S DISEASE

Ruben Riordan, *Linus Pauling Institute, Corvallis, Oregon, United States*

Abstract The accumulation of senescent cells contributes to aging pathologies, including neurodegenerative diseases, and its selective removal improves physiological and cognitive function in wild type mice as well as in Alzheimer's disease (AD) models. AD models recapitulate some, but not all components of disease and do so at different rates. Whether brain cellular senescence is recapitulated in some or all AD models, and whether the emergence of cellular senescence in AD mouse models occurs before or after the expected onset of AD-like cognitive deficits in these models is not yet known. The goal of this study was to identify mouse models of AD and AD-related dementias that develop measurable markers of cellular senescence in brain and thus may be useful to study the role of cellular senescence in these conditions. We measured levels of cellular senescence markers in brains of P301S(PS19), P301L, hTau, and 3xTg-AD mice that model amyloidopathy and/or tauopathy in AD and related dementias, and in wild type, age-matched control mice for each strain. Expression of cellular senescence markers in brains of transgenic P301L and 3xTg-AD mice was largely indistinguishable from that in WT control age-matched mice. In contrast, markers of cellular senescence were significantly increased in brains of transgenic P301S and hTau mice as compared to WT control mice at the expected time of onset of AD-like cognitive deficits. Taken together, our data suggest that P301S(PS19) and hTau mice may be useful for the study of brain cellular senescence in tauopathies including, but not limited to, AD.

CARE EXPERIENCES AND EXPECTATIONS OF OLDER SEXUAL MINORITY ADULTS

Mekiyala Singleton, and Susan Enguidanos, *University of Southern California, Los Angeles, California, United States*

Sexual minority (SM) adults have unique care needs and experiences, partially because they receive and give care by and to “chosen family”. This study examines the care experiences and expectations of diverse SM adults. Using data from the 2018 AARP Survey “Maintaining Dignity: Understanding and Responding to the Challenges Facing Older LGBT Americans,” logistic and ordinal regressions were conducted to examine associations with care experiences (i.e., provided caregiving and received caregiving) and care expectations (i.e., likelihood of having to provide care and need care) among SM respondents. Gender was highly associated with care experiences, with female respondents being 70% and 74% more likely to have provided caregiving [OR:1.71, SE=.26; $p<0.001$] and received caregiving [OR:1.74, SE=.22; $p<0.001$]. Relationship status was significantly associated with care expectations, with those who were married/civil union/domestic being 4 times [OR:4.0, SE=.52; $p<0.001$] and those in a relationship being 3 times [OR:3.3, SE=.51; $p<0.001$] more likely to expect that they will provide care in the future. Those same respondents had a 64% [OR:1.64, SE=.21, $p<0.001$] and 55% [OR:1.55, SE=.23, $p<0.01$] greater odds of reporting being “very likely” that they will need care in the future. Additionally, older age, being a racial minority, having higher education, and being

employed were significantly and positively associated with care experiences and expectations. These findings provide a deeper insight into how SM individuals of different backgrounds experience and anticipate different aspects of caregiving. Moreover, we will discuss how our findings compare to non-SM individuals and implications of these findings.

CAREGIVING AND COVID-19: PERSPECTIVES FROM A CARE COACH

Kelly Marnfeldt,¹ Lilly Estenson,¹ Julia Rowan,¹ and Kathleen Wilber,² 1. *University of Southern California, Los Angeles, California, United States*, 2. *University of Southern California, University of Southern California, California, United States*

Family caregivers of community-dwelling older adults have faced unprecedented caregiving challenges during the COVID-19 pandemic. Examining the accumulated impact on family caregivers can help health and aging service providers design resources and supports that are resilient to emergency situations, and reduce negative psychological and physical consequences and risk of abuse within caregiving dyads. Data was collected as part of a pilot intervention in which “Care Coaches” provided telephonic coaching sessions to family caregivers of older adults. We examined Care Coach observations documented after coaching sessions with 24 family caregivers between March 2020 and February 2021. Two coders employed thematic analysis to generate codes and themes. The sample was 70% female, 80% were the spouse or significant other of their care receiver, the mean age was 61, and 53% were Non-Hispanic White. Themes and sub-themes included: (1) increased caregiver burden and diminished care networks due to fear of exposure to or contraction of COVID-19, (2) barriers to accessing in-home personal assistance services and home-delivered meals despite intervention efforts, and (3) the exacerbation of caregiver social isolation due to COVID-19 lockdown policies. Findings highlight the ways in which COVID-19 has amplified caregiver burden through the breakdown of formal and informal support systems. Potential adaptations of community-based services for older adults and their caregivers include remote service liaisons and need assessment of caregiver dyads to assure access to home-based personal assistance services and nutrition support for those at greatest risk of negative consequences during emergency service lapses.

CBOS' CAPACITY AND RESILIENCE ON SERVING OLDER AA AND NHPI ADULTS DURING THE PANDEMIC

Eun Jeong Lee,¹ KeliAnne Hara-Hubbard,² Sonia Bishop,³ Jae Lim,⁴ and Linda Ko,² 1. *Asian American Resource and Information Network, Wood Ridge, New Jersey, United States*, 2. *University of Washington, Seattle, Washington, United States*, 3. *Fred Hutchinson Cancer Research Center, Seattle, Washington, United States*, 4. *Swedish Health Services, Seattle, Washington, United States*

Community-based organizations (CBOs) are essential settings for older Asian American (AA) and Native Hawaiian Pacific Islander (NHPI) adults for accessing culturally and linguistically appropriate services and connecting with and support each other. This study examined the impact of the COVID-19 pandemic on CBOs' ability to serve older AA &

NHPI adults. This mixed methods study (survey and semi-structured interviews) used a sequential exploratory design. We recruited 65 leaders and staff members from 40 CBOs serving older AA & NHPI adults nationally. Descriptive analysis was conducted with the survey data followed by thematic analysis of the interview data. Many CBOs were impacted by the increased demands for services (80%) and created new services (75%) while experiencing programming disruption (69%), decreased staffing (55%), and loss of revenue (38%). Some CBOs temporarily closed their organizations (38%), while others closed permanently (3%). To remain in operation, many CBOs (65%) increased their online presence, hired staff (52%), and recurred to financial reserves (20%). The semi-structured interviews identified four themes: 1) CBOs resourcefulness to acquire and share resources, 2) technology as a connector for CBOs and an isolator for older adults, 3) heightened racial discrimination against Asians, and 4) emergence of multi-level resilience (personal/ community/organizational). CBOs experienced disruption in their operation, and heightened racial discrimination during the pandemic. Yet, CBO's ability to remain resilient was critical to continue to provide key programs for older adults. Future studies may want to examine evolving needs of CBOs as they adjust to new public health challenges during the pandemic.

CHALLENGE OR OPPORTUNITY? IMPACTS OF FALLS AMONG OLDER ADULTS LIVING WITH DEMENTIA ON THEIR CARE PARTNERS

Yuanjin Zhou,¹ Emily Ishado,² and Tatiana Sadak,² 1. *The University of Texas at Austin, Austin, Texas, United States*, 2. *University of Washington, Seattle, Seattle, Washington, United States*

Previous studies suggest that falls among community-dwelling older adults living with dementia (OLWD) harm the health and wellbeing of their family/friend care partners. However, little is known about the process through which falls impact care partners. We conducted a grounded theory analysis using 59 semi-structured interviews with care partners of OLWD who were recently hospitalized and had a history of falls. We identified several areas of care partners' functioning that were affected by falls in positive and negative ways: everyday life, health management for OLWD, and interactions with healthcare providers. Both the fall events and fall risks had negative consequences of reducing care partners' self-care activities and work productivity. Other adverse consequences of fall risks were (1) care partners' fatigue and conflicts with OLWD due to the intense requirement of daily monitoring, and (2) hesitance to ask healthcare providers for assistance because clinicians frequently did not teach care partners how to address fall risks and might recommend institutionalization. However, OLWD's fall events became a transition point for some care partners to seek support and gain more information and skills about managing OLWD's health conditions, which might reduce care partners' burden in the long term. Because OLWD's falls may have negative and positive consequences for care partners, both problem-solving and strength-based fall management approaches are needed. These strategies focus on developing and sustaining care partners' self-care, developing collaborative relationships with OLWD, enhancing successful capacity

for OLWD's health management, and cultivating partnerships with healthcare providers.

CHALLENGES AND BENEFITS: VOLUNTEERISM AMONG OLDER ADULTS DURING COVID-19

Alicia Sellon,¹ Tina K. Newsham,² Renee DuMont,¹ Claire Hollifield,³ and Alicia Thomas,³ 1. *University of North Carolina Wilmington, Wilmington, North Carolina, United States*, 2. *University of North Carolina Wilmington, University of North Carolina Wilmington, North Carolina, United States*, 3. *University of North Carolina Wilmington, wilmingon, North Carolina, United States*

Social distancing restrictions and regulations, put in place to reduce the spread of COVID-19, disrupted the daily lives of active older adult volunteers. One year into the pandemic, we used a mixed-methods approach to explore how these regulations had impacted the quality of life, loneliness, and volunteer behavior of 26 older adults who were active volunteers (i.e., at least an hour a week) prior to the start of the pandemic. All the participants were white and non-Hispanic, and the majority were female (65.4%). The average age was 71, with a range from 53 to 87 years old. On average, participant scores on the UCLA loneliness scale (4.23 ± 1.39) indicated a low amount of loneliness and high scores on the Brunsviken Brief Quality of Life (BBQ) scale (83.54 ± 10.97) indicated a high quality of life. Thematic findings from the interviews conveyed that, despite the challenges and risks associated with volunteering during a pandemic, participants valued volunteer work enough to make adjustments or seek out new volunteer activities. The research team identified two overarching themes related to participants' discussions of volunteering during the pandemic: Challenges and changes and Benefits of volunteering during a pandemic. Participants' discussions of how volunteer work changed and why they continued to or sought out new volunteer activities during a pandemic can guide organizations seeking to support or recruit older volunteers, particularly as the pandemic continues. These findings also provide further evidence of the important role that volunteerism can play in the well-being of older adults.

CLINICAL AND UTILIZATION OUTCOMES OF MATCHED PEOPLE WITH AND WITHOUT HIV AGED 65+

Brianne Olivieri-Mui,¹ Sandra Shi,² Gahee Oh,³ Ellen McCarthy,⁴ Ira Wilson,⁵ Monty Montano,⁶ and Dae Hyun Kim,⁴ 1. *Hebrew SeniorLife, Boston, Massachusetts, United States*, 2. *Hebrew SeniorLife, Harvard Medical School, Roslindale, Massachusetts, United States*, 3. *Hinda and Arthur Marcus Institute for Aging Research, Roslindale, Massachusetts, United States*, 4. *Hebrew SeniorLife, Roslindale, Massachusetts, United States*, 5. *Brown University, Providence, Rhode Island, United States*, 6. *Brigham and Women's Hospital, Boston, Massachusetts, United States*

The prevalence of age-standardized comorbidities is significantly elevated for PLWH across an array of cohorts. However, healthcare needs of older people living with (PLWH) and without (PWOH) HIV may be similar if they have similar geriatric conditions. PLWH and PWOH aged 65+ and eligible for Medicare from 7/1/2014-1/1/2015 were

matched 1:1 on age, sex, race, and census region (n=7654). Cox regression assessed count of prevalent geriatric conditions (dementia, depression, falls, hip fracture, sensory deficits, osteoporosis, orthostatic hypotension, urinary incontinence, frailty, and polypharmacy), and risk for clinical or utilization outcomes (cancer, kidney disease, muscle wasting, hepatitis C, liver disease, myocardial infarction, stroke; hospitalization, nursing home and home health admission) during follow-up between 1/1/2015-12/31/2016. PLWH and PWOH are similar in count of geriatric conditions. Compared to those with none, those having 2+ geriatric conditions were similar across PLWH and PWOH in their risk of ≥ 1 clinical outcome (PLWH: HR 1.57 95% CI [1.29-1.90]; PWOH: HR 1.31 [1.02-1.67]), hospitalization (PLWH: HR 2.35 [1.96-2.83]; PWOH: HR 2.07 [1.65-2.60]), and home health admission (PLWH: HR 2.09 [1.58-2.76]; PWOH: HR 2.20 [1.55-3.12]). Having 2+ geriatric conditions, PWOH had 4.45 times the risk (95% CI 3.16-6.26) and PLWH had 2.88 times the risk (95% CI 2.18-3.81) of NH admission compared to no geriatric conditions. In this study, PLWH use nursing homes less than PWOH despite having a similar number of geriatric conditions and clinical outcomes. Further research to understand this apparent discrepancy will be critical to achieve equity in nursing home access.

CLOSING THE LOOP: AN ENVIRONMENTAL SCAN OF APS-REPORTER FEEDBACK POLICIES AND PRACTICES

Olanike Ojelabi,¹ Randi Campetti,¹ Kathy Greenlee,² and Kristin Lees Haggerty,³ 1. *Education Development Center, Waltham, Massachusetts, United States*, 2. *Greenlee Global LLC, Greenlee Global LLC, Kansas, United States*, 3. *Education Development Center, West Roxbury, Massachusetts, United States*

Abuse, neglect, and exploitation of older adults are prevalent and underreported in the United States. Pathways to identifying and resolving cases of abuse against older adults depend on mandated and non-mandated reporters bringing attention to these cases through reports to Adult Protective Services (APS). However, existing research points to several barriers to reporting. One significant barrier is a lack of communication from APS to reporters about reports they have made (e.g., whether the report is appropriate for APS, the investigation outcome, and services provided by APS). This lack of reciprocal communication likely serves as a disincentive for future reporting. This study aims to promote improved communication between APS and reporters by examining the legal, ethical, and practical barriers and facilitators to communication at key points in the reporting and response pathways. In this first phase of the project, we conducted an environmental scan of policies and practices related to reporting, investigation, and feedback. Early results from the environmental scan suggest most APS agencies (81%) do not currently provide feedback to reporters. Among those providing feedback, 20% provide feedback only to mandated reporters, and 50% provide only procedural feedback, which focuses on the process of receiving and screening reports for investigation and not on the outcome of the investigation. In the next phase of this study, we will supplement these findings through interviews with APS leaders across the U.S.

These early results will begin to fill an important gap in the understanding of feedback loops between APS and reporters.

COGNITIVE STIMULATION THERAPY IN OUTPATIENT SETTINGS FOR PERSONS WITH DEMENTIA

Max Zubatsky,¹ Marla Berg-Weger,² Matthew Amick,³ Debbie Blessing,⁴ Katelyn Sansone,³ Anna Brende,² and Janice lundy,⁵ 1. *Medical Family Therapy Program, Saint Louis University, Missouri, United States*, 2. *Saint Louis University, Saint Louis, Missouri, United States*, 3. *Saint Louis University, Saint Louis University, Missouri, United States*, 4. *A.T. Still University of Health Sciences, A.T. Still University, Missouri, United States*, 5. *Perry County Memorial Hospital, Perry County Memorial Hospital, Missouri, United States*

Cognitive Stimulation Therapy (CST) is a non-pharmacologic evidence-based intervention for persons living with mild to moderate dementia. This clinical intervention therapy follows a structured protocol designed to connect people with memory loss to others by providing opportunities for social engagement and group discussion of current events and a different themed activity each session. This presentation will include findings from a multi-site study of the group intervention conducted in an urban and two rural out-patient settings with community-dwelling older adults. Pre- and post-assessments captured data on cognitive function, depression, quality-of-life, and mobility. While CST is offered in over 30 countries, this is the first large-scale CST study conducted in the U.S. Implications for future practice and research will be presented.

COMPARISON OF OLDER ADULT AND HEALTHCARE PROVIDER BELIEFS ABOUT FALL PREVENTION STRATEGIES

Gwen Bergen, Ankita Henry, and Yara Haddad, *Centers for Disease Control and Prevention (CDC), Atlanta, Georgia, United States*

Older adults reported about 36 million falls in 2018. Although effective strategies are available to minimize fall risk, little is known about older adults' and healthcare providers' awareness of these strategies. This study describes and compares older adults' and healthcare providers' beliefs about fall prevention strategies. Demographic and fall-related data for older adults were obtained from the 2019 fall cohort of Porter Novelli ConsumerStyles. Similar data from primary care practitioners, nurse practitioners, and physician assistants, were gathered from the 2019 cohort of DocStyles. Percentages and 95% confidence intervals were calculated to compare older adults and providers. Most providers (91.3%) and older adults (85.1%) believed falls can be prevented. High percentages of providers and older adults identified strength and balance exercises (90.7% and 82.8% respectively) and making homes safer (90.5% and 79.9% respectively) as strategies that help prevent falls. More providers reported that Tai Chi (45.7%) and managing medications (84.2%) can prevent falls compared to older adults (21.7% and 24.0% respectively; $p < 0.0001$). Sizable percentages of providers and older adults endorsed less evidence-based strategies including aerobic exercise (70.7% and 58.4% respectively) and being more careful (69.3% and

81.6% respectively). Among older adults, lower endorsement of evidence-based strategies (e.g., Tai Chi, medication management) coupled with higher endorsement of limited evidence-based strategies (e.g., being careful, aerobic exercise) suggest some older adults lack awareness of effective fall prevention interventions. Increased patient and provider communication can increase awareness about the benefits of evidence-based strategies for fall prevention.

COMPARISON OF PHYSICAL ACTIVITY LEVEL FROM OSTEOPOROSIS, PARKINSON AND HEALTHY SUBJECTS

Seong Hyun Moon,¹ Thurmon Lockhart,¹ and Krupa Doshi,² 1. *Arizona State University, Tempe, Arizona, United States*, 2. *MAYO Clinic, Scottsdale, Arizona, United States*

Lifestyle at the habitation immensely affects the progression of various illnesses, such as Osteoporosis and Parkinson's disease (PD). These disorders lead patients to a sedentary lifestyle and result in significantly less movement compared to the average healthy individual. The combination of these backgrounds escalates the percentage of fall incidents. Quantifying physical activity levels from longitudinal Activities of Daily Living (ADL) data of these disease patients could stipulate intuition of their fall mechanisms. The objective of this study is to compare the osteoporosis, Parkinson's disease, and healthy group's physical activity level from their ADL. For this study total of eighteen subjects participated (healthy=6, osteoporosis=6, PD=6). The result indicated that the dynamic physical activity level for the healthy subject was 13.2%, the osteoporosis subject was 7.9%, and the PD subject was 7.0%. This indicates that there was a significant decline in physical activity level for the PD compared to healthy subjects ($P = 0.0024^*$). Also, a comparison between healthy and osteoporosis subjects showed a significant difference ($P = 0.0066^*$). Lastly, the physical activity level of PD and osteoporosis subjects did not have a significant difference among them ($P = 0.6276$). The aim of this study was to evaluate the physical activity level of the osteoporosis, PD, and healthy subjects. The systematic approach of collecting physical activity levels with the Inertial Measurement Unit (IMU) device allowed researchers to collect the quantitative data of ADL. In this experiment, healthy subjects were significantly more physically active compared to osteoporosis and PD patients.

COMPARISONS OF FACTORS ASSOCIATED WITH SUICIDAL IDEATION OF OLDER INDIVIDUALS BY HEALTH STATUS

Hyeyeon Sung,¹ Jihun Na,² Sungkyu Lee,¹ and Sehyun Baek,¹ 1. *Soongsil University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Korea Center on Gambling Problems, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

This study examined the factors associated with suicidal ideation among older individuals and compared those factors by their objective and subjective health status. Data were obtained from the 13th wave of the Korean Health Panel Survey in 2018. The sample of 6,283 older individuals, who are 55 years and older, was classified into four groups by their objective and subjective health status. Objective health status was measured by the number of chronic health conditions,

and subjective health status was defined by an individual's self-reported health status. To examine the factors associated with suicidal ideation among four groups of older individuals, logistic regression analyses were conducted after controlling for socio-demographic characteristics, physical health and mental health characteristics. The results show that depression and anxiety were found as common factors associated with suicidal ideation for all four groups. As for the group of older individuals who reported bad objective health and bad subjective health, younger age, being male, and low educational attainment were found to be associated with suicidal ideation. For those with bad objective health regardless of their subjective health status, the level of stress was found to be related to suicidal ideation among older individuals. Based upon those results, the present study discussed practical and policy implications for suicide prevention among older individuals by reflecting their objective health and subjective health status.

COMPLEMENTARY AND INTEGRATIVE HEALTH APPROACHES AND OPIOID PRESCRIPTIONS AMONG OLDER VETERANS WITH CHRONIC PAIN

Ling Han,¹ Joseph Goulet,² Melissa Skanderson,² Doug Redd,³ Cynthia Brandt,⁴ and Qing Zeng,⁵ 1. *Yale School of Medicine, New Haven, Connecticut, United States*, 2. *VA Connecticut Healthcare System, West Haven, Connecticut, United States*, 3. *Washington DC VA Medical Center, Washington DC, District of Columbia, United States*, 4. *Yale School of Public Health, West Haven, Connecticut, United States*, 5. *George Washington University, Washington DC, District of Columbia, United States*

Complementary and integrative health (CIH) approaches are recommended in national guidelines as viable options for managing chronic pain and de-prescribing opioids. We followed 1,993,455 Veterans with musculoskeletal disorders for two years who were not using opioids at study entry. CIH exposure was ascertained from primary care visits for acupuncture, massage and chiropractic care via natural language processing and structured data. Opioid prescriptions during the 2-year follow-up were abstracted from Veterans Health Administration (VHA) electronic pharmacy records. Propensity score (PS) was used to match CIH recipients with non-recipients with most comparable baseline characteristics. Overall, 140,902 (7.1%) Veterans received CIH, with a prevalence of 2.7% for Veterans aged ≥ 65 y, comparing to 6.3% and 10.5% for those aged 50-64y and ≤ 49 y, respectively. Among the 1:1 PS-matched sub-cohort (136,148 pairs), Cox proportional hazard model revealed that time to fill first opioid prescriptions was significantly longer for CIH recipients (mean: 587 days) than non-recipients (mean: 491 days), with adjusted Hazard Ratio of 0.48 (95% Confidence Interval (CI): 0.45-0.51) for Veterans ≥ 65 y, 0.44 (95% CI: 0.43-0.45) for 50-64y and 0.47 (95% CI: 0.46-0.48) for age ≤ 49 y group (p value for interaction, 0.003). Sensitivity analyses among full cohort or modeling total supply of first opioid prescriptions derived consistent results. These findings suggest potential benefit of CIH use in delaying and reducing opioids prescriptions for patients with chronic pain and may have implication for older Veterans ≥ 65 y who have been found less likely to seek CIH therapies than their younger counterparts.

COUPLING EFFECTS OF DEPRESSION AND FUNCTIONAL DISABILITY: USING BIVARIATE LATENT CHANGE SCORE MODEL

Gina Lee, and Peter Martin, *Iowa State University, Ames, Iowa, United States*

The purpose of the study was to examine the coupling effect of depression and functional disability over four time points using the data from the Health and Retirement Study (HRS). The sample included participants who survived to 98 years or older (N = 458). Four alternative latent change score models were computed to examine the univariate and bivariate effects among depressive symptoms (CES-D) and functional disabilities (ADL): No-coupling, univariate model of ADL to change in CES-D, univariate model of CES-D to change in ADL, and bivariate model. As hypothesized, the no-coupling model did not fit the data well, $\chi^2(26) = 164.86$, CFI = 0.85, RMSEA = 0.11. Model 2, ADL predicting change in CES-D, did not fit the data well, $\chi^2(25) = 164.18$, CFI = 0.85, RMSEA = 0.11. Model 3, CES-D predicting change in ADL, also did not fit the data, $\chi^2(25) = 148.06$, CFI = 0.87, RMSEA = 0.10. The bivariate model fit the data well, $\chi^2(21) = 66.94$, CFI = 0.95, RMSEA = 0.07, and was the best fitting model. All level to change effects were significant in model 4. One's CES-D at prior waves was positively associated with change in ADL at subsequent waves, and ADL at prior waves was positively associated with change in CES-D at subsequent waves. In conclusion, there is a significant coupling effect between depressive symptoms and ADL over time. Future health policies should monitor older adults' mental and functional health simultaneously for their possible spillover effects.

COVID-19 IN HOSPITALIZED PATIENTS ADMITTED FROM SKILLED NURSING FACILITIES: FACTORS ASSOCIATED WITH MORTALITY

Rongfang Zhan,¹ Cheng Yin,¹ and Liam O'Neill,² 1. *University of North Texas, Corinth, Texas, United States*, 2. *University of North Texas, University of North Texas, Texas, United States*

Background: Nursing home residents were impacted disproportionately by the coronavirus because of their vulnerabilities. Although many studies concentrated on risk factors associated with mortality of hospitalized patients, there were limited studies epitomizing them from skilled nursing facilities to hospitals. The study aims to identify inpatients' characteristics on demographics, hospital admission types, insurance types, and chronic diseases associated with mortality among our cohort patients in Texas. Methods: Individuals above 50 years, diagnosed with Covid-19, and admitted from skilled nursing facilities were included in the retrospective cohort study. Pearson's Chi-Square and Mann-Whitney tests were applied to measure four major perspectives between survivors and non-survivors. Then, a binary logistic regression was employed to determine the association between independent variables and mortality. Results: A total of 218 patients were included in the study, of which 54 (24.8%) died during hospitalization. According to the univariate analysis, expired patients were more likely to be emergency admission (p = 0.001), elective admission (p = 0.02), Medicaid as primary payment (p = 0.034), heart disease (p = 0.027), CKD (p = 0.03), and hypertension (p = 0.002). The binary logistic

regression revealed that hypertension (OR = 3.176, 95% CI: 1.200-8.409, $p = 0.02$) and Medicaid (OR = 2.637, 95% CI: 1.287-5.405, $p = 0.008$) as primary payment had significantly high odds of mortality. Conclusion: Hypertension and Medicaid as primary payment are the strongest predictive factors associated with mortality and suggest that hospitals in Texas distribute critical care and resources while prevent and treat them to increase survival rates.

CULTURAL CONSIDERATIONS TO THE LIFE PARTICIPATION APPROACH IN APHASIA: A FILIPINO CASE STUDY

Hanna Ulatowska,¹ Tricia Olea Santos,² and Carla Krishan Cuadro,³ 1. *University of Texas, Dallas, Texas, United States*, 2. *University of Texas at Dallas, Dallas, Texas, United States*, 3. *St. Luke's Medical Center, Quezon City, National Capital Region, Philippines*

Stroke is among the common causes of chronic disability (Feigin, 2014). Around one-third of stroke survivors are affected by aphasia, a communication disorder affecting the ability to comprehend and express oneself (Dickey, et. al., 2010). Culture is essential to understanding aphasia and providing person-centered care. Philippine cultural identity is reflected via respect for older persons, collectivism in family and community, and devotion to religion (Pe Pua & Protacio-Marcelino, 2000). The Filipino family is a primary support system, and cultural values directly influence caregiving approaches in chronic disability. This single case study examines the life of a Filipino man who has successfully lived with aphasia for over 25 years. Having finished a doctorate from Harvard University, served as the youngest University president, and member of the Philippine government, he suddenly had a stroke and was able to communicate only via single words, gestures, and facial expressions. His life is discussed in the context of the unique, multi-modal communication system which developed through the years with his family. Music and symbolism via watercolor paintings also define his aphasia journey. The value of religion in Filipino culture (Cruz, et. al., 2019) and its role in fostering positivity in his aphasia journey is examined. This study also highlights Filipino collectivism through the support of family and community in addressing communication needs and facilitating meaningful relationships at various stages in life. Cultural values deeply rooted in Filipino caregiving, such as debt of gratitude and filial devotion to parents (Enriquez, 1992), are discussed.

DEVELOPMENT AND VALIDATION OF A MEASURE OF SUPERVISORY BEST PRACTICES IN GERONTOLOGICAL SOCIAL WORK

Daniel Kaplan,¹ and Keith Chan,² 1. *Adelphi University, Cortlandt Manor, New York, United States*, 2. *Hunter College, New York, New York, United States*

Agency-based supervision is essential to skilled practice and staff retention, directly impacting the quality of services. The Supervisory Leaders in Aging (SLA) program was designed to strengthen supervision of the aging services workforce. SLA was implemented in four states and trained 134 social work supervisors. The purpose of this study was to develop a novel, comprehensive, and practice-informed measure of supervisory best-practices in gerontological social services.

The primary outcome for the SLA program was the Practice Inventory for Supervision in Aging Services (PISAS), which evaluated the frequency of recent use of best practices as identified by the project team and vetted by instructors and an interdisciplinary advisory board. Reliability and confirmatory factor analyses were conducted to examine its psychometric properties. Findings demonstrated the scale had good internal consistency reliability ($\alpha = 0.88$). Confirmatory factor analyses indicated a three-factor solution, 1) Gerontological Social Work Skills, 2) Program Development Skills, and 3) Supervision and Leadership Skills, accounting for 72% of the variability in the 27 items. Gerontological Social Work Skills captured best practices regarding mental health in late life, heightening awareness of elder abuse, and working with families. Program Development Skills captured assessment, measuring outcomes, and translating evidence into practice. Supervision and Leadership Skills captured individual supervision, group supervision and leadership in interdisciplinary practice. Results indicated that PISAS is a reliable and valid measure of use of best practices in gerontological social work supervision. Further implications and limitations of this measure in assessing outcomes of gerontological education and training programs are discussed.

DEVELOPMENT OF AN ADL-PRACTICE GUIDELINE: THE NEXT STEP TOWARDS GUIDANCE IN ESSENTIAL NURSING CARE ACTIVITIES

Svenja Cremer,¹ Michel Bleijlevens,¹ Silke Metzethin,¹ Janneke de Man-van Ginkel,² and Sandra Zwakhalen,³ 1. *Maastricht University, Maastricht, Limburg, Netherlands*, 2. *UMC Utrecht, Utrecht, Utrecht, Netherlands*, 3. *Maastricht University, Maastricht, Limburg, Netherlands*

Supporting and respecting care receivers in Activities of Daily Living (ADL) lies at the essence of nursing care, irrespective of diagnosis or healthcare setting. ADL-care is an intimate form of caring, and therefore close and personal to the care receiver, aiming to enhance their independence and comfort. Even though ADL-care is indispensable and highly valued by care receivers, the scientific foundation of ADL-care is weak. This leaves nursing professionals with insufficient guidance as to what constitutes quality ADL-care and what activities are necessary and effective. Therefore, we developed an ADL practice guideline according to the framework of the Dutch Institute for Health (AQUA-guideline) and AGREE II. The guideline was developed over three stages: (1) Determination of the target population and scope, (2) Analysis of problems leading to guiding questions and answering these based on literature search and consensus, (3) Testing and validation. A multidisciplinary working group determined the purpose, target group, and five clinical questions. We used literature search and consensus procedures to answer these questions in close collaboration with care receivers and professional care providers. This guideline provides guidance for nursing professionals to choose appropriate ADL-care options in five modules covering recommendations: (1) Involving care receivers in ADL-related care choices, (2) Identifying ADL-care needs, (3) Choosing effective interventions to enhance ADL-independence and comfort, (4) Supporting informal caregivers in ADL-care, and (5) Using ADL-care for early detection of health problems. These modules are considered leading for future

developments in essential nursing care and will be evaluated in a pilot implementation.

DISCOURSE ANALYSIS UNCOVERS COMPULSORY ALTRUISM AND POWER PARADOXES FOR FAMILY CAREGIVERS OF THOSE WITH DEMENTIA

Candace Harrington, *University of Louisville School of Nursing, Louisville, Kentucky, United States*

Rural female family caregivers are under-represented, under-reported, and under-studied in rural caregiving and Alzheimer's disease-related dementias (ADRD) research. Caregivers' power struggles are often invisible and unknown. These constructs have social, policy, and practice implications for both family caregivers and their care recipients with ADRD. The purpose of this study was to explore how Foucauldian discourse analysis (FDA) elucidates rural female family caregivers' acquisition of caregiving roles for those with ADRD. FDA focuses on power structures and relationships in society as expressed through language and practices that affect marginalized groups. Textual data for this secondary analysis consisted of 157 pages of interview transcripts with 10 rural female caregivers. The systematic discourse analysis elucidated two socially constructed power and relationship structures. Compulsory altruism described complex socially constructed caregiving and gender role expectations, grounded in reciprocity, duty, and filial piety. A power paradox occurred when filial piety, duty, and reciprocity were in direct opposition to the caregivers' beliefs and value systems. In this sample, the subsequent sense of ambiguity about violating personhood and autonomy delayed black and white caregivers' responses to intervene with family members with ADRD. These delays resulted in near misses from wandering, driving-related accidents, cooking-related fires, financial exploitation by other family members, mistreatment that involved both caregiving dyad partners, and one tragic incident of a parent's death resulting from wandering-related exposure to elements. FDA was a valuable qualitative approach to elucidate family caregivers' power struggles that were previously invisible and unknown. These findings have broad implications for clinicians and researchers.

DIVERSITY, EQUITY AND INCLUSION IN AN AGE-FRIENDLY HEALTH SYSTEM

Elizabeth Eckstrom,¹ Emily Morgan,² Bryanna De Lima,¹ and Anna Pleet,³ 1. *Oregon Health & Science University, Portland, Oregon, United States*, 2. *Oregon Health and Science University, Portland, Oregon, United States*, 3. *Vita-Salute San Raffaele University, Milan, Lombardia, Italy*

The Age-Friendly Health Systems (AFHS) initiative uses a 4Ms framework to encourage patient-centered care for older adults. Many health systems have implemented the core elements of AFHS – What Matters, Mentation (Cognition and Depression), Medications, and Mobility – with the goal to uniformly apply these elements to all patients 65 years and older. However, equity in AFHS delivery has not yet been examined. Five diversity, equity, and inclusion (DEI) factors, including gender, race, ethnicity, preferred language and MyChart activation, were cross-sectionally analyzed against the 4Ms framework for patients seen (in person or virtual visit) in an academic internal medicine clinic between April

2020 and April 2021 (N= 3370) using two-way contingency tables. Preferred language, gender, and MyChart activation yielded significant pairings with the 4M metrics. For the AFHS What Matters metric, females were 1.10 times more likely than males and English-speaking patients were 1.67 times more likely than non-English speaking patients to receive advance care planning (p <0.01). Females and patients with MyChart activation were about 2.0 times more likely to have a high-risk medication on their medication list compared to males and patients without MyChart activation (p <0.01). MyChart activation was also significantly associated with cognitive screening. Patients with MyChart activation were 1.09 times more likely than patients without MyChart activation to get cognitive screening (p <0.001). This study, the first to incorporate demographic data, into AFHS quality measures, suggest a need to develop best practices for equitable Age-Friendly care at the clinical team and the institutional policy level.

DO FAMILY CAREGIVERS OF DEMENTIA PATIENTS FEEL COMPETENT IN PAIN MANAGEMENT?

Hui Zhao,¹ Pamela Kulbok,² Ishan Williams,² Carol Manning,² and Rafael Romo,³ 1. *James Madison University, Harrisonburg, Virginia, United States*, 2. *University of Virginia, Charlottesville, Virginia, United States*, 3. *Dominican University of California, San Rafael, California, United States*

Older adults with dementia rely on others to recognize and treat their pain and will ultimately become dependent. Family caregivers (FCGs) play a crucial role in pain management, yet limited data is available regarding the factors that impact their abilities. This qualitative descriptive study sought a deep understanding of FCGs perception of their abilities to manage pain for a loved-one with dementia. A sample of 25 adult family caregivers of community-based older adults with dementia was recruited in central Virginia. Participants were 29 to 95 years old, predominantly white, married, female, and high school graduates. We conducted semi-structured interviews that were audio recorded and analyzed using constant comparative analysis. Participants' who perceived greater competence with pain management reported less pain for their loved-one, and their level of confidence was influenced by 3 factors: progress and stage of dementia: this increases the complexity of care, affecting FCGs ability to manage pain and engendering a self-perception of incompetence; developing adaptive mechanisms: built self-efficacy and improved FCGs perceived competence; and support from professionals: a greater degree of support alleviated FCGs concerns and instill new skills, Effective pain management depended on family caregivers' belief in their own abilities, and perceived competence could be improved by learning new skills or making adaptations. Professional care givers need to routinely assess FCGs abilities and provide adequate interventions.

EFFECTS OF A WEB-BASED INTERVENTION ON CARDIOVASCULAR AND PHYSICAL HEALTH OF KOREAN OLDER ADULTS DURING THE PANDEMIC SOONHYUNG KWON,¹ and Oejin Shin,² 1. *University of Illinois at Urbana-Champaign, Savoy, Illinois, United States*, 2. *University of Illinois at Urbana Champaign, Savoy, Illinois, United States*

During the lockdown, 97.5% of Korean senior centers in South Korea were closed to prevent the spread of the coronavirus disease 2019 (COVID-19). The threat of the COVID-19 presented the need for alternative interventions for Korean older adults to maintain cardiovascular and physical health. Korean senior centers implemented web-based interventions to provide physical health services, but their effectiveness was not yet assessed. Thus, our study aimed to identify the effects of a web-based intervention using a smartwatch and mobile app in older adults when compared to center-based intervention during the pandemic. This study collected 117 Korean older adults (≥ 60) who participated in the 12-week web-based and center-based physical interventions using a smartwatch and mobile app. This quasi-experimental study was conducted between August and December in 2020. We analyzed the pre-posttest of cardiovascular and physical health across two intervention types. Our regression results indicated that participants in the 12-week web-based intervention reported better cardiovascular (systolic blood pressure: $b = -13.77$, $p < .001$; cholesterol: $b = -11.71$, $p < .05$) and physical health (muscular function: $b = 2.99$, $p < .001$; body balance: $b = -1.31$, $p < .001$; cardiopulmonary endurance: $b = 33.33$, $p < .001$) than those in center-based intervention at posttest. The findings imply a web-based intervention is likely to become an innovative therapeutic strategy for older adults' health to respond to the rapidly changing social service systems amid the pandemic.

EFFECTS OF NON-PHARMACOLOGICAL INTERVENTIONS ON ELDERLY IN NURSING HOMES WITH SLEEP DISORDER: A META-ANALYSIS

Sunok Jung, Eunju Choi, and Hyeyoung Kim, *College of Nursing, Ewha Womans University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Purpose: This study aimed to examine the effects of nonpharmacological sleep intervention programs to improve sleep quality among the elderly in long-term care facilities. **Methods:** A literature search and selection was performed on nine different databases using the Preferred Reporting Items for Systematic Review and Meta-Analysis Statement. In total, 14 studies met the inclusion criteria and were systematically reviewed. For the meta-analysis, the effect size was estimated using the random-effects model on Review Manager (RevMan) desktop version 5.4 of the Cochrane Library. **Result:** The meta-analysis of nonpharmacological interventions obtained a total effect size of 1.0 (standardized mean difference [SMD] = 1.0, 95% confidence interval [CI]: 0.64–1.35), which was statistically significant ($Z = 5.55$, $p < .001$). The most frequent nonpharmacological interventions identified were the interventions using aroma; the effect size was 0.61 (SMD = 0.61, 95% CI: 0.14–1.08), which was statistically significant ($Z = 2.55$, $p = .01$). In subgroup analysis, group-specific interventions, interventions for >4 weeks, and untreated control studies were more effective. **Conclusion:** This study confirms that nonpharmacological interventions are effective in improving sleep quality among the elderly in long-term care facilities. However, the small sample size and risk of bias in assessing the interventions of individual studies are unclear or high, thereby limiting the generalizability of the results. Further studies based on randomized control trials and the development of evidence-based interventions

that consider the elderly participants' physical activity levels, intervention methods and duration, and control group selection are needed to obtain more conclusive evidence.

END-OF-LIFE CARE FACTORS PREDICT AFFECTIVE SEQUENCES IN OLDER ADULTS' FINAL MEMORIES OF SPOUSAL LOSS

Emily Mroz,¹ Nerea Anaya-Dominguez,² and Susan Bluck,³
 1. *Yale University, New Haven, Connecticut, United States,*
 2. *University of Florida- Life Story Lab, Gainesville, Florida, United States,* 3. *University of Florida, University of Florida, Florida, United States*

Memories from the dying days of a deceased spouse are vividly recalled and can guide grief adjustment in older adulthood (Mroz & Bluck, 2018). End-of-life factors (e.g., place of death, quality of death) likely impact the nature of recall of such memories over time. Intersecting psychology and palliative care perspectives, the current study employs mixed-methods to examine relations between end-of-life care factors and affective sequences in older adults' final memories of spousal loss. Fifty-three participants (Mage = 81.59; M = 6.81 years since loss) completed a Final Memory Interview, provided place of spousal death (in hospital, outside of hospital), and completed the Good Death Inventory (GDI; Miyashita et al., 2008). GDI responses were organized into four quality of death categories. Final memories were reliably content analyzed for affective sequences (i.e., positive and negative affect themes; interrater agreements $> .70$): redemption (bad mitigated by good, McAdams 1999), contamination (good spoiled by bad; McAdams, 1998), positive stability, and negative stability. Loss of a spouse in hospital, compared to outside of hospital, related to narrating final memories with contamination, $F = 4.05$, $p < .05$. Quality of death predicted narration of final memories with positive affective sequences: lower reported comforting environment related to redemption ($t = -3.05$; $p < .01$) and higher reported appropriate medical care related to positive stability ($t = 2.60$; $p < .05$) in memories. As healthcare provision continues to adjust to improve end-of-life circumstances across care environments, the impact of circumstances on close others should factor into initiative development.

ENGAGING UNDERREPRESENTED OLDER ADULTS IN ADRD AND AGING RESEARCH: A SCOPING REVIEW

Nisha Godbole,¹ Jeannette Beasley,² Simona Kwon,³ Timothy Roberts,⁴ Julie Kranick,⁵ Scott Sherman,² Chau Trinh-Shevrin,² and Joshua Chodosh,² 1. *NYU Grossman School of Medicine, South Setauket, New York, United States,* 2. *NYU Grossman School of Medicine, New York, New York, United States,* 3. *NYU School of Medicine, New York, New York, United States,* 4. *NYU Langone Health, New York, New York, United States,* 5. *NYU Langone Medical Center, NYU Langone Medical Center, New York, United States*

The rapidly aging and diversifying U.S. population coincides with increases in prevalence of Alzheimer's disease and related dementias (ADRD) and other aging-related disorders. Unfortunately, older adults and racial and ethnic minorities are often underrepresented in research studies. The differing barriers that underrepresented older adults face in research

engagement indicate that results from studies conducted on younger and majority populations may not maintain external validity outside of those groups. Therefore, efforts to engage diverse older adults in research is imperative. The goal of this scoping review was to summarize findings of the current state of National Institute on Aging (NIA) sponsored research, identifying extant literature on engaging diverse older adult populations in aging and ADRD research. Among 566 articles screened for inclusion, 436 were included in the final analysis. Results showed that African Americans were represented in over half the studies (63.5%), but Native Hawaiian/Pacific Islander and American Indian or Alaska Native populations were not well represented. Community- and convenience-based recruitment and retention strategies that have demonstrated prior success in research engagement were widely utilized. Racial, ethnic, and income status breakdowns were not included in 30.0%, 57.1%, and 53.4% of studies respectively, making it difficult to assess the applicability of findings for particular groups. Inclusion of Alzheimer's disease patients or those with mild cognitive impairments was also poorly defined in most studies. Findings highlight gaps in existing literature that can be used to inform future research, and recruitment and retention strategies for engaging racial and ethnic minority older adults in research.

EVALUATING THE CONVERSATION STARTER KIT IN LONG TERM CARE: A CANADIAN PERSPECTIVE

Sharon Kaasalainen,¹ and Tamara Sussman,² 1. *McMaster University, Hamilton, Ontario, Canada*, 2. *McGill University, McGill University, Quebec, Canada*

This study evaluated an advance care planning intervention, the Conversation Starter Kit (CSK) booklet, for use in long term care (LTC) homes. This study used a quasi-experimental, one group pre/post design. Quantitative surveys were administered before and after a 3-month advance care planning intervention (CSK booklet). Data were collected at three LTC homes in southern Ontario. We collected data from 55 resident who were able to make decisions on their own paired with 11 family members of these residents. We also collected data from 24 family members of residents who were not able to make decisions on their own. Quantitative surveys were administered before and after the intervention. An additional structured interview was completed at the end of the intervention period, which included both closed and open-ended questions to assess perceptions about the CSK booklet's use or non-use. Residents reported higher engagement in advance care planning after having completed the CSK booklet than before, particularly related to asking questions to health care providers about health care decisions. Family members reported feeling very certain that they would be able to make decisions on behalf of the resident but they felt less certain after completing the CSK booklet, implying that the CSK booklet raised their awareness of the types of decisions that they might need to make, hopefully triggering them to become more prepared for these decisions in the future. The CSK appears acceptable, easy to use for residents and family members/friends in LTC, and can improve resident engagement in ACP.

EXPERIENCES AND PERCEIVED ORIGINS OF COMPASSIONATE AGEISM AMONG OLDER ADULTS DURING THE COVID-19 PANDEMIC

Catherine Ju,¹ Meghan McDarby,² Matthew Picchiello,³ and Brian Carpenter,⁴ 1. *Washington University St. Louis, St. Louis, Missouri, United States*, 2. *Washington University, St. Louis, Missouri, United States*, 3. *Washington University in St. Louis, Olivette, Missouri, United States*, 4. *Washington University in St. Louis, Saint Louis, Missouri, United States*

During the COVID-19 pandemic, there was a rise in media messages (MMs) and interpersonal behaviors (IBs) that could have been considered as reflecting compassionate ageism (i.e., ageism that stems from perceptions of older adults [OAs] as warm but incompetent). However, it is unclear how OAs experienced these MMs and IBs during the pandemic. The current study examined how OAs perceived pandemic-related MMs and IBs. We recruited 74 community-dwelling OAs (Mage = 73.18, 58% female). Participants completed a survey in which they reported the extent to which they had encountered five MMs and nine IBs throughout the COVID-19 pandemic. Then, participants rated whether they believed each MM and IB was motivated by care and how offended they were by it. Nearly all participants had encountered MMs about OAs' vulnerability to COVID-19 (e.g., more likely to contract COVID-19, 97%; more likely to die from COVID-19, 97%). Furthermore, most participants experienced IBs emphasizing their vulnerability to COVID-19 (e.g., told by another person they had a higher likelihood of contracting COVID-19, 64%; someone had checked in on them unprompted, 63%). However, across MMs and IBs, most participants (59–100%) perceived them as motivated by care and concern, and a relatively small proportion (0–20%) reported being offended by them. Our findings underscore the importance of understanding nuances of ageism from the perspective of OAs themselves. Different forms of ageism (i.e., compassionate ageism, hostile ageism) rooted in certain stereotypes about older adults (i.e., high warmth-low competence) may uniquely shape the lived experiences of OAs.

EXPERIENCES AND PERCEPTIONS OF USING A LOW-COST PET ROBOT FOR OLDER ADULTS AND PEOPLE WITH DEMENTIA

Wei Qi Koh,¹ Sally Whelan,¹ Pascale Heins,² Dymphna Casey,¹ Elaine Toomey,³ and Rose-Marie Dröes,⁴ 1. *National University of Ireland Galway, Galway, Galway, Ireland*, 2. *Maastricht University, Maastricht, Limburg, Netherlands*, 3. *University of Limerick, Limerick, Limerick, Ireland*, 4. *Vrije Universiteit Amsterdam (Amsterdam UMC), Amsterdam, Noord-Holland, Netherlands*

Pet robots are a practicable substitute for animal-assisted therapy. They have been shown to have positive impacts on older adults, including people with dementia, such as providing companionship and facilitating social interaction. However, the issue of affordability can hinder equal access to such technology. The purpose of our study was to understand the perceptions and experiences of using a low-cost, commercially available pet robot with older adults and people with dementia. We used a novel methodology of analysing a large volume of user reviews that were collected from 15

consumer websites. A total of 1,327 user reviews that met our pre-specified inclusion criteria were included. Descriptive statistics was applied to characterise demographic data, and inductive qualitative content analysis was used to identify themes in the textual data. Most reviews were obtained from consumer sites in the United States, and most reviewers were family members of the users (i.e., older adults and people with dementia). We found that circumstantial reasons, such as the inability to own live animals, prompted reviewers to purchase the pet robot. Most reviewers had positive perceptions of the pet robot, and described various activities that users engaged in with it. Impacts of using the pet robot, such as positive emotions, were also described. Finally, experiences about practical aspects of its use, such as durability and hygiene, were discussed. Overall, this study provides useful knowledge that can help researchers, robot developers and clinicians understand the viability of using low-cost pet robots to benefit older adults, including people with dementia.

EXPLORING THE PATIENT-PROVIDER RELATIONSHIP IN OLDER ADULT PAIN MANAGEMENT

Sophia Sheikh,¹ Jennifer Brailsford,² Jason Beneciuk,³ Monika Patel,⁴ Brittany Johnson,⁵ Robin Moorman Li,⁵ Phyllis Hendry,⁶ and Natalie Mitchell,⁶ 1. *UF College of Medicine Jacksonville*, 2. *UF Health Jacksonville, Jacksonville, Florida, United States*, 3. *Brooks Rehabilitation and the College of Public Health & Health Professions at the University of Florida, Jacksonville, Florida, United States*, 4. *University of Florida College of Medicine – Jacksonville, Jacksonville, Florida, United States*, 5. *University of Florida College of Pharmacy, Jacksonville, Florida, United States*, 6. *UF College of Medicine Jacksonville, Jacksonville, Florida, United States*

Successful health outcomes in older patients are linked to the quality of the patient-provider relationship. Our study objective was to further understand the role of this relationship specific to pain management through perspectives from older adults and healthcare providers. Semi-structured interviews and focus groups were conducted with 9 older adults and 11 multidisciplinary healthcare providers. Transcripts were analyzed using a thematic analysis. Three main concepts emerged: (1) defining pain management goals — differences in providers and patients' goals for pain and function, with sub-themes of realistic goal setting and a shift in pain treatment to minimize opioids as a first-line medication; (2) communication — perceived gap in providers communicating and coordinating across disciplines and with patients, with sub-themes of improving positive communication and inconsistent messaging among providers; and (3) therapeutic alliance — all parties feel that developing a relationship is built on consistent trust and open dialogue. Although providers and older adults often expressed similar perspectives, there were several areas of misalignment identified within each concept, representing areas of disconnect within the patient-provider pain management relationship. Our findings indicate providers could benefit from education on improving communication around realistic goals and patient-centered outcomes and incorporation of more holistic pain management approaches when working with older adult patients.

Further study should focus on developing educational interventions to address the identified shortcomings.

FACTORS INFLUENCING BRAIN HEALTHY DIETS AMONG OLDER MIDWESTERN AFRICAN AMERICANS

Ashley Shaw,¹ Samantha Fikru,¹ Jannette Berkley-Patton,² Chris Goode,³ Jaime Perales,⁴ and Eric Vidoni,⁴ 1. *University of Kansas Medical Center, Kansas City, Kansas, United States*, 2. *University of Missouri-Kansas City, Kansas City, Missouri, United States*, 3. *Ruby Jean's Juicery, Kansas City, Missouri, United States*, 4. *University of Kansas Medical Center, Fairway, Kansas, United States*

Emerging evidence suggests that up to half of Alzheimer's disease (AD) cases are a result of modifiable risk factors related to poor diet such as blood pressure and diabetes, disproportionately affecting African Americans. Adherence to brain healthy diets remains low among African Americans. Therefore, it is important to understand needs, preferences, and barriers to inform intervention designs aimed to reduce AD risk among African Americans. Using a qualitative community-based research approach, we conducted six semi-structured focus group discussions (n= 30) to explore older African American experiences with brain healthy diets, preferences, and barriers to eating healthy. Secondly, we assessed the feasibility and acceptability of collecting biomarkers of health status and dietary behaviors among African Americans. A thematic analysis was conducted to identify emerging themes and biomarkers of health status were analyzed using descriptive statistics. We identified four themes: "Knowledge and Beliefs about Brain Healthy Diets," "Eating Practices," "Ways to Improve Dietary Practices," and "Preferences for Enhancing Awareness about Brain Healthy Diets." Themes indicated that older African Americans are receptive to healthy dietary consumption but perceived lack of education, cost, access, and perception of losing one's culture as barriers to adherence. A total of 87.5% of participants completed biomarker assessments and 82% tested positive for 1 or more cardiovascular risk factor. Our study identified ways to enhance brain healthy dietary practices to reduce dementia risk. Also, our study demonstrated feasibility and acceptability in collecting AD related biomarkers in the African American community.

FACTORS INFLUENCING IMPLEMENTATION OF EHEALTH TECHNOLOGIES TO SUPPORT INFORMAL DEMENTIA CARE: AN UMBRELLA REVIEW

Sofia Bastoni,¹ Christian Wrede,² Marcia C. da Silva,³ Robbert Sanderma,¹ Andrea Gaggioli,⁴ Annemarie Braakman-Jansen,¹ and Lisette van Gemert-Pijnen,¹ 1. *University of Twente, Enschede, Overijssel, Netherlands*, 2. *University of Twente, Dept. of Psychology, Health & Technology, Enschede, Overijssel, Netherlands*, 3. *University of Twente, Enschede, Overijssel, Netherlands*, 4. *Università Cattolica del Sacro Cuore, Università Cattolica del Sacro Cuore, Lombardia, Italy*

The increase of People with Dementia (PwD) living at home underscores the need for innovative eHealth technologies that support both patients and informal caregivers (IC). Sustainable implementation of eHealth technologies within this target group can, however, be difficult. Our study aims

at providing an overview of (1) technologies employed in the context of informal dementia care (IDC) and (2) factors influencing the implementation of these technologies. Five databases were searched for (systematic) reviews. 21 reviews were included. A combination of deductive and inductive thematic analysis was performed, using the NASSS Framework to organize the findings. We identified technologies used “by IC”, “by PwD” and “with PwD”. Most represented technologies included: (i) devices for in-home monitoring (ii) technologies for supporting memory, orientation, and day structure, and (iii) communication technologies. Most factors influencing implementation related to the condition of dementia, characteristics of the technology, the expected/perceived value by users, and the characteristics of the IC. Considerably less has been reported on factors related to the implementing organization, the technology supplier, the wider institutional and sociocultural context of policy and regulations, and the adaptation of technology over time. Our study 1) created a comprehensive overview of eHealth technologies employed in the context of IDC and contributes to a better understanding of factors influencing their implementation, and 2) uncovered a knowledge gap regarding success factors for implementation related to the wider context. Although future research is needed, these findings can help researchers improving the development and implementation of eHealth technologies to support IDC.

FACTORS RELATED TO THE CARE MANAGEMENT PRACTICE FOR OLD PUBLIC ASSISTANCE RECIPIENTS IN OSAKA CITY OF JAPAN

Takako Ayabe,¹ Yoshihito Takemoto,² Shinichi OKADA,³ Johannes Kiener,⁴ and Masakazu SHIRASAWA,⁵ 1. *BAIKA Women's university, Ibaraki, Osaka, Japan*, 2. *Okayama Prefectural University, Soja, Okayama, Japan*, 3. *Osaka City University, Osaka, Osaka, Japan*, 4. *Saitama University, Saitama, Saitama, Japan*, 5. *International University of Health and Welfare, Minato City, Tokyo, Japan*

The research was conducted between January 22 and February 25, 2021. The data was collected by self-administered questionnaires mailed to the participants at 800 care management centers and comprehensive community support centers in Osaka City. The centers were randomly selected. The response rate was 19.1%. The independent variables were: obtaining the qualification of a Senior Care Manager (SCM), who was a qualified person that acquired advanced knowledge and skills in care management by advanced training; experience years in Social Work (SW); experience years in care management; experiences in training programs for team approach; and experiences in training programs for supporting Old Public Assistance Recipients (OPAR). The dependent variables were the categorized contents in the Care Management Practice for old public assistance recipients. They were: Care planning and Implementation (CI); Assessment; Financial Support and Evaluation (FSE); Contract and Explanations in care management; Coordinating Informal support and Formal services in Care planning; and Arrangements in Financial supports for Formal service costs. The Structural Equation Modeling was performed for the examinations of the relationships. As a result, the goodness of the fit indices was acceptable, and we retained the models. In correlational

analyses, CI and Assessment were significantly correlated with SCM ($p < .05$). FSE was significantly correlated with SW ($p < .001$) and OPAR ($p < .05$). In conclusion, the results implied that advanced qualification of a Senior Care Manager and a specified training program for supporting old public assistance recipients were effective in providing appropriate care management services.

FAMILY CAREGIVING IN THE SOMALI-AMERICAN COMMUNITY DURING COVID-19

Rajeana Moone,¹ Kamal Suleiman,² and Elizabeth Lightfoot,³ 1. *University of Minnesota, Woodbury, Minnesota, United States*, 2. *University of Pennsylvania, Woodbury, Minnesota, United States*, 3. *Arizona State University, Woodbury, Minnesota, United States*

This poster describes a study of Somali American family caregiving during the COVID-19 pandemic, specifically investigating the unique caregiving challenges faced by Somali caregivers. The findings from this study, which was part of a larger study related to family caregiving, were drawn from in-depth interviews of ten Somali family caregivers in Minnesota. All interviews were conducted in Somali during the summer of 2020 and translated and transcribed by a certified translator and research assistant. The major themes that emerged from this study related to Visitation, Hospital Accompaniment, and Self Sacrifice. As Somali culture is centered around extended family connections, isolation places particular strain. Second, family members typically serve as advocates, translators and guides during hospital visits. The restrictions on hospital accompaniment due to COVID-19 caused increased stress and poorer care of family caregivers and their loved ones. Third, in the Somali community, family placement is a last resort. Caregivers reported great sacrifices in time, comfort and opportunities to care for family members during COVID-19. Most of the caregivers described their coping with these sacrifices in terms of radical acceptance and God consciousness. These findings have important implications for providing supports for Somali family caregivers.

FEASIBILITY OF AN INNOVATIVE REHABILITATION PROGRAM ADAPTED FOR THE POST-ACUTE NURSING HOME SETTING

Addie Middleton,¹ Jane Driver,² Marcus Ruopp,² Lindsay Lefers,² Jessica Rawlins,² Rebekah Harris,³ and Jonathan Bean,³ 1. *VA Boston, Boston, Massachusetts, United States*, 2. *VA Boston Healthcare System, Brockton, Massachusetts, United States*, 3. *VA Boston Healthcare System, VA Boston Healthcare System, Massachusetts, United States*

Live Long Walk Strong is a rehabilitation program that produces large clinically meaningful improvements in mobility when implemented as an outpatient program for older adults. We adapted Live Long Walk Strong for the post-acute nursing home setting within the Veterans Health Administration as a clinical demonstration project. The adapted version includes novel elements and bridges the inpatient stay and three months post-discharge. The inpatient phase focuses on maximizing functional recovery and includes activities focused on timing and coordination of gait, leg strength and power, and trunk muscle endurance. The care transition and virtual (telehealth) post-discharge phase

focuses on case management and engagement in physical activity programs. Coaching and behavior change are a consistent focus throughout the program. To date, 13 Veterans (mean age 67.9, SD 11.7 years) have completed the inpatient phase, and of those Veterans, six have completed the entire program, five are still active, one was lost to follow-up, and one was rehospitalized. The program demonstrates feasibility, 91% of all inpatient sessions and 81% of all post-discharge sessions were completed. Regarding preliminary efficacy, 83% of Veterans who completed the program exceeded the minimal detectable change score (4 points) on the Activity Measure for Post-Acute Care (AM-PAC) Mobility scale from program enrollment to completion (mean change 6.5, SD 6.9 points). Based on findings from this clinical demonstration project, the program is feasible. However, future research is needed to further examine the program's impact on mobility and other outcomes important to older Veterans receiving post-acute nursing home care.

FEASIBILITY TRIAL OF AN INTEGRATED TREATMENT "ACTIVATE FOR LIFE" FOR PHYSICAL AND MENTAL WELL-BEING IN OLDER ADULTS

Melba Hernandez-Tejada,¹ Alexis Nagel,² Mohan Madiseti,² Sundaravadivel Balasubramanian,² and Teresa Kelechi,² 1. *University of Texas HSC at Houston, Houston, Texas, United States*, 2. *Medical University of South Carolina, Charleston, South Carolina, United States*

This study describes the feasibility and patient satisfaction for an integrated treatment to address multiple health outcomes in a sample of older adults living in a low-income independent residence facility and their own homes in the community. Specifically, 30 older adults were offered the opportunity to participate in a feasibility study of different components of Activate for Life treatment targeting balance and physical strength (Otago Exercise Program), breathing retraining (Gentle Yoga and Yogic Breathing), and mental health (Behavioral Activation for Depression). Three treatment combinations were compared in a randomized repeated measures design to determine if adding components to the existing Otago program were feasible and if this affected patient satisfaction. Arm1: the Otago strength and balance program alone (n = 10); Arm 2: Otago + Gentle Yoga and Yogic Breathing (n = 10); and Arm 3: Otago + Gentle Yoga and Yogic Breathing + Behavioral Activation (we named this combination 'Activate for Life' n = 10). Dependent measures included recruitment rate, session completion characteristics, and satisfaction with the program. Overall, study and treatment components proved feasible, and participants reported high satisfaction with all 3 Arms.

FOOD ACCESS, DIET QUALITY, AND NUTRITIONAL STATUS OF OLDER ADULTS DURING COVID-19: A SCOPING REVIEW

Kimson Johnson,¹ Emily Nicklett,² Lisa M. Troy,³ Maitreyi Vartak,² and Ann Reiter,² 1. *University of Michigan, Ann Arbor, Michigan, United States*, 2. *The University of Texas at San Antonio, San Antonio, Texas, United States*, 3. *University of Massachusetts Amherst, University of Massachusetts Amherst, Massachusetts, United States*

COVID-19 has imposed challenges for older adults to access food, particularly in minority, lower income, and rural communities. However, the impact of COVID-19 on food access, diet quality, and nutrition of diverse older adult populations has not been systematically assessed. The objective of this study is to examine changes in food access, diet quality, and nutritional status among older adults during the COVID-19 pandemic and the potential differential impacts of the COVID-19 pandemic on these nutrition-related outcomes using the framework of the socio-ecological model. An electronic search was conducted using three databases (PubMed, CINAHL, and Web of Science) on March 7, 2021. Original, peer-reviewed English-language studies published 10/1/2019-3/1/2021 were considered for which the age of participants was 50 years and older (average age range 50-98). In order to be considered, studies must have examined food access, food security, or nutrition constructs as an outcome. The initial search yielded 13,628 results, of which 9,145 were duplicates. Of the remaining 4,483 articles, 13 articles were in scope and therefore selected in the final analysis, which can be characterized as descriptive (n=5), analytical (n=6), and correlational (n=2). Studies were conducted among community-dwelling older adult populations (n=7) as well as those temporarily residing in hospital settings (n=6) in 10 countries. More research is needed to examine the impact of COVID-19 on food access/security and the differential barriers experienced by older adult populations.

GENERATIONAL MULTIMORBIDITY DISEASE CLUSTERS FOR BRITISH COHORTS BORN 1921 – 1960

Stacey Voll,¹ Graciela Muniz-Terrera,² and Scott Hofer,¹ 1. *University of Victoria, Victoria, British Columbia, Canada*, 2. *University of Edinburgh, Edinburgh, Scotland, United Kingdom*

The aim of this study is the first step in our understanding of the uniqueness and stability of multimorbidity disease patterns for different generations. The unique historical context that each generation has been exposed to is thought to have systemic health impacts and differences in epidemiological make-up (Clouston et al. 2021). Literature suggests that multimorbidity disease patterns, are similar across countries (Hernandez et al, 2021 – in press) and observational points, and that migration into complex disease clusters is more common as people age (Cassell et al, 2018, Kingston et al. 2018). Most commonly reported are Cardiovascular and Metabolic disease clusters which lead to lower quality of life, mortality and morbidity (Kudesia, 2021). We asked: Do multimorbidity disease patterns differ for unique generations? Using the ELSA, the disease clusters of three cohorts were examined; an older cohort, born 1921-1930, a middle cohort born 1931-1940 a younger cohort born 1941-1950 and the "newest" cohort, born 1951-1960. Self-reported dementia and memory problems lead a specific cluster for the middle cohort, those born in 1931-1940, but not for the other cohorts. While disease patterns were different between sex for other clusters, the disease cluster of dementia and memory problems held similar disease patterns for males and females, with a prevalence of 3%. The dementia/memory problem cluster loaded with cardio/metabolic diseases. This suggests that complex multimorbidity for the British 1931-1940 cohort has had an impact related to dementia and

memory problem diagnoses for this specific generation, for males and females alike.

HEALTH AND FINANCIAL RISK-TAKING PROPENSITY DURING THE COVID-19 PANDEMIC: DIFFERENCES BY AGE AND TIME

Bariş Sevi, and Natalie Shook, *University of Connecticut, Storrs, Connecticut, United States*

The COVID-19 pandemic has presented a global health threat of unprecedented magnitude and had a devastating impact on the world's economy. Accordingly, the riskiness of decisions related to health and finance may have increased. However, health and financial threats have differentially affected different age groups. For example, COVID-19 posed a greater health threat to older adults (65+ years) than younger or middle-aged adults, whereas financial threat due to the pandemic affected younger and middle-aged adults more than older adults. This study examined differences in the levels of health and financial risk-taking propensity by time of the pandemic and age group: young (18-39 years), middle-aged (40-64 years), and older adults (65+ years). A sample of 488 individuals residing in the US (245 Woman; Mage = 51.07, SD = 15.99) completed three waves of surveys in March, April, and May 2020. We found that risk-taking propensity for both health and financial decisions decreased over time. The risk-taking propensity was significantly lower in April and May than March, but risk-taking propensity in April and May did not significantly differ. The three age groups were all significantly different than each other in both health and financial risk-taking propensity at all three waves. Younger adults reported higher risk-taking propensity than older and middle-aged adults, and middle-aged adults reported higher risk-taking propensity than older adults. The findings indicate that the pandemic may have influenced all individuals to take less risks in the fields of health and finance regardless of their age.

HOUSING COST BURDEN AND WELL-BEING IN OLDER ADULTS MODERATED BY NEIGHBORHOOD COHESION AND DISORDER

Ji Hyang Cheon,¹ Min Kyoung Park,² and Todd Becker,³

1. *University of Maryland Baltimore, University of Maryland Baltimore, Maryland, United States*, 2. *University of Maryland Baltimore County, Baltimore, Maryland, United States*, 3. *University of Maryland, Baltimore, Baltimore, Maryland, United States*

Although aging in the community promotes well-being in older adults, contextual factors (e.g., housing cost burden, neighborhood cohesion, neighborhood disorder) may impact this relationship. Identifying such risk factors represents a first step toward improving older adult well-being. NHATS data (Rounds 5–8) were used to answer two research questions (RQs). RQ1: “Is housing cost burden significantly associated with well-being?” RQ2: “Is this association further moderated by neighborhood cohesion and neighborhood disorder?” Participants were 18,311 adults ≥ 65 years old. Well-being was assessed by summing 11 commonly identified indicators. Two items were merged to assess housing cost burden (categories: “no burden,” “no money for utilities,” “no money for rent,” and “no money for utilities or rent”). Neighborhood cohesion and disorder were combined

(categories: “no cohesion, no disorder,” “yes cohesion, no disorder,” “no cohesion, yes disorder,” and “yes cohesion, yes disorder”). Both RQs were assessed through a random coefficient model controlling for established covariates. RQ1 results revealed that, compared to “no burden,” “no money for utilities or rent” ($B = -1.22$, $p = .003$) and “no money for rent” ($B = -1.50$, $p = .007$) were significantly associated with well-being. RQ2 results revealed that “no cohesion, no disorder” significantly moderated the association between “no money for utilities or rent” and well-being ($B = -2.44$, $p = .011$). These results indicate that increased housing cost burden is associated with decreased well-being, especially for those reporting no neighborhood cohesion. Future research should examine neighborhood-level protective factors promoting cohesion for older adults to support well-being.

HOW DO FAMILY CAREGIVERS' VALUES INFLUENCE PAIN MANAGEMENT FOR OLDER ADULTS WITH DEMENTIA?

Hui Zhao,¹ Pamela Kulbok,² Ishan Williams,²

Carol Manning,² and Rafael Romo,³ 1. *James Madison University, Harrisonburg, Virginia, United States*, 2.

University of Virginia, Charlottesville, Virginia, United States, 3. *Dominican University of California, San Rafael, California, United States*

California, United States

Professional caregivers rely on formal training when managing pain among patients with dementia, but family caregivers (FCGs) lack this foundation. Instead, FCGs use informal sources that may reflect a values-driven decision-making process. Few studies have examined how FCGs' personal values impact pain management for dementia patients. We sought to examine the influence of personal values on pain management among FCGs for community-dwelling older adults with dementia using qualitative descriptive methods. Twenty-five adult FCGs, aged from 29 to 95, were recruited in central Virginia. Participants were predominantly white, married, female, and high school graduates. We conducted semi-structured interviews that were audio recorded and analyzed using constant comparative analysis. Four themes emerged: 1) Priority for pain management: when quality of life is valued over other factors (i.e., length of life), priorities focused on no pain, leading to better pain management; 2) Moral perspectives: negative views toward drugs, especially opioids, led to less use and greater report of pain; 3) Beliefs about alternative therapy: negative views led to less likely use of non-traditional approaches and reports of more pain, and 4) Personal experience of pain: past personal experiences of pain (negative or positive) influenced the priority placed on pain management and the FCG's ability to provide effective pain management. The diverse views held by FCGs demonstrate a value-based process and suggest a modifiable factor in pain management. Helping FCGs reflect biases while reinforcing values that improve pain management would lead to improve pain and quality of life for older adults with dementia.

HOW LONELY ARE OLDER AMERICANS ACT NATIONAL FAMILY CAREGIVER SUPPORT PROGRAM PARTICIPANTS?

Claire Pendergrast,¹ and Heather Menne,² 1. *Syracuse*

University, Syracuse, New York, United States, 2. *RTI, RTI, District of Columbia, United States*

Older Americans Act (OAA) family caregiver services connect family members caring for older adults with a diversity of community-based resources and supports. Social isolation and loneliness are known public health threats, and family caregivers may face greater vulnerability to loneliness given the often-intensive time demands of care provision. Policy stakeholders and aging services providers are increasingly focused on combating loneliness among older adults and family caregivers. To inform efforts to reduce loneliness, we conducted descriptive analyses to identify characteristics of the participants in the OAA National Family Caregiver Support Program associated with higher rates of loneliness, measured with the 3-item UCLA Loneliness Scale. Using data from the 2019 National Survey of Older Americans Act Participants, we examined how caregiver loneliness varied based on caregiver age, gender, income, race and ethnicity, living alone, rurality, and self-reported health, as well as care recipients' health status and difficulties with ADLs. Among our sample of 1,824 family caregivers, rates of loneliness were high overall (70%). Loneliness was significantly higher for caregivers with poor health (71.4%), incomes less than \$20,000 (75.3%), living alone (75.4%), aged 65 or older (73.2%), Hispanic caregivers (82.2%) and caregivers for care recipients with 3 or more ADLs (76.0%). Findings underscore the importance of increasing social engagement opportunities for family caregivers. Policies and programs focused on reducing caregiver loneliness should be accessible to all family caregivers but should prioritize outreach and engagement for groups at higher risk of loneliness.

IMPACT OF IN2L TABLETS ON LONELINESS AND WELL-BEING: FINDINGS OF AN INNOVATIVE INDUSTRY-AAA PROGRAM

Lydia Nguyen,¹ Karen O'Hern,² Adam Siak,² Kristi Stoglin,² and Charlotte Mather-Taylor,³ 1. *iN 2. L, Denver, Colorado, United States*, 2. *iN2. L, Greenwood Village, Colorado, United States*, 3. *Area Agency on Aging of Broward County, Sunrise, Florida, United States*

Area Agency on Aging (AAA) senior and adult day centers closed due to COVID-19, causing many older adults to lose an important source of connection and engagement, leading to social isolation. To combat negative consequences, iN2L and a Florida AAA partnered on an innovative program providing iN2L tablets to AAA-supported older adults to use at home. The tablets have a simple interface, content specifically designed for older adults (e.g., games; music; movies), and video call capability. Participants included 51 independent older adults (mean age 77) and 39 family caregivers (mean age 59) of people with dementia. Participants completed phone surveys with AAA case managers at baseline and 3 months, including UCLA Loneliness Scale (3 item) and questions about their tablet experiences. Findings show positive trends for loneliness and well-being in both groups. At 3 months, lonely participants decreased from baseline by 25% for independent older adults and 18% for family caregivers. Over 80% of independent older adults agreed the tablet engages them in meaningful activities, provides daily enjoyment, and helps with relaxation. For family caregivers, 79% agreed the tablet is another tool in their caregiver toolkit and about 70% agreed the tablet adds daily enjoyment, helps with relaxation, and provides engagement in meaningful

activities for their family member. Approximately 50% of caregivers felt happier, less stressed, and less irritable since using the tablets. This work has implications for the utility of technology in promoting engagement and connection, alleviating negative effects of social isolation, and the effectiveness of industry-AAA partnerships.

IMPACTS OF THE PANDEMIC ON OLDER ADULTS' SOCIAL ISOLATION

Stephanie MacLeod, *UnitedHealth Group, United States*

The risk of COVID-19 exposure and likelihood of severe illness have been critical concerns among older adults during the pandemic. Meanwhile, social distancing has worsened social isolation, with severe impacts on connectedness among seniors. Effects of the pandemic may lead to an extended crisis, with impacts on health outcomes. Our primary purpose was to summarize emerging research describing impacts of the pandemic on social isolation and related health outcomes among older adults. A streamlined search was conducted to fit the scope of this review, with key terms determined to identify relevant publications. Common research databases and mainstream resources were utilized. We focused on research published or released since the start of 2020, primarily rapidly reviewed studies, to align with the timing of the pandemic. Early research suggests that the pandemic has worsened social isolation among older adults. Social isolation is now more urgent, as many seniors lost their usual connections due to social distancing. While these measures help to prevent virus exposure, this approach must be balanced with maintaining social connectedness. Thus, a "COVID-19 paradox" has emerged: safety protocols protect older adults but concurrently place them at risk of social isolation. Adapted approaches are urgently needed to safely address the consequences of a potential long-term social recession.

IN VIVO QUASI-ELASTIC LIGHT SCATTERING EYE SCANNER DETECTS MOLECULAR AGING IN HUMANS AND MICE

Douglas Parsons,¹ Olga Minaeva,¹ Srikant Sarangi,¹ Danielle Ledoux,² Juliet Moncaster,¹ John Clark,³ David Hunter,² and Lee Goldstein,¹ 1. *Boston University School of Medicine, Boston, Massachusetts, United States*, 2. *Boston Children's Hospital, Boston, Massachusetts, United States*, 3. *University of Washington, Seattle, Washington, United States*

The absence of clinical tools to evaluate individual variation in the pace of aging represents a major impediment to understanding aging and maximizing health throughout life. The lens is an ideal tissue for quantitative assessment of molecular aging in vivo. Long-lived proteins in lens fiber cells are expressed during fetal life, do not undergo turnover, accumulate molecular alterations throughout life, and are optically accessible in vivo. We used quasi-elastic light scattering (QLS) to measure age-dependent signals in lenses of both healthy human subjects and wild-type C57BL/6 mice. Age-dependent QLS signal changes detected in vivo in humans and mice recapitulated time-dependent changes in hydrodynamic radius, protein polydispersity, and supra-molecular order of human lens proteins during long-term incubation (~1 year) and in response to sustained oxidation

(~2.5 months) in vitro. Our findings demonstrate that QLS analysis of lens proteins provides a practical technique for noninvasive assessment of molecular aging in vivo.

INTERGENERATIONAL TUTORING: OLDER ADULTS SUPPORTING CHILDREN'S ACADEMIC NEEDS VIA VIDEO CONFERENCING

Jessica Hoffman,¹ Edward Miller,² Jeffrey Burr,³ Jan Mutchler,² James Hermelbracht,⁴ Robert Volpe,¹ Robin Coddling,⁵ and Amy Briesch,⁶ 1. *Northeastern University, Boston, Massachusetts, United States*, 2. *University of Massachusetts Boston, Boston, Massachusetts, United States*, 3. *McCormack Graduate School, Boston, Massachusetts, United States*, 4. *University of Massachusetts Boston, University of Massachusetts Boston, Massachusetts, United States*, 5. *Northeastern University, Northeastern University, Minnesota, United States*, 6. *Northeastern University, Northeastern University, Massachusetts, United States*

COVID-19 resulted in societal disruptions across the lifespan. School (K-12) closures were among the most challenging impacts of the virus, leaving many parents with the burden of schooling their children at home. Another major impact of the virus was the social isolation and loneliness felt by many retired, older adults, who were sheltering at home. The disruptions of COVID-19 led our inter-professional team to develop the Intergenerational Tutoring program. Intergenerational Tutoring addresses a service delivery gap in schools because tutors expand schools' capacity to implement evidence-based instruction with students in need of individual support. At the same time, research shows that meaningful volunteering supports the well-being of older adults across physical, psychosocial and cognitive dimensions of health. The aim of the Intergenerational Tutoring program is to pair older adults with kindergarten children in high needs schools to implement early literacy interventions remotely via Zoom. Our poster will describe the Intergenerational Tutoring program including tutor training and tutoring implementation. We will summarize the initial findings from our pilot study conducted in spring and summer 2021 with tutors and children. Data will include (1) themes from tutor interviews regarding the personal meaningfulness of the program and the program's associated benefits and challenges; (2) implementation fidelity data; (3) impact of tutoring on children's early literacy skills; and (4) parent feedback. We will summarize lessons learned and next steps for the program.

INTERSECTIONS OF AGEISM AND GENDER STIGMA: EXPLORING LONG-TERM CARE EMPLOYEES' ATTITUDES TOWARDS AGING

Tarah Loy-Ashe,¹ and Brent Hawkins,² 1. *Southern CT State University, New Haven, Connecticut, United States*, 2. *University of North Carolina Wilmington, Wilmington, North Carolina, United States*

The purpose of this mixed methods, single case study was to explore long-term care (LTC) employees' attitudes towards age and gender. The intersection of Rosemary Garland-Thomson's theory of feminist disability (2001) and Hailee Gibbons' compulsory youthfulness theory (2016) provided the conceptual framework for this project. The sample consisted of 60 LTC direct care employees, all employed at the same organization,

who completed an on-line survey during the COVID-19 pandemic. The survey consisted of demographic questions and the Fraboni Scale of Ageism. Twenty-one of these employees participated in a 30-45 minute phone interview. Cultural artifacts were also collected. All data were collected during the COVID-19 pandemic. Although quantitative results showed no statistical significance, qualitative results suggest that employees do exhibit some ageist attitudes towards the residents for whom they care. Despite evidence that most employees felt a deep connection with residents, they detached themselves from the aging process. The theoretical framework lends hand in explaining how both ableism and ageism appeared to contribute to this detachment. Findings indicated employees' interactions and attitudes towards residents were influenced by themes compassionate ageism, ableism, and identity, which resulted in meta theme caregiver validation and reward. Employees received validation and altruistic reward from positive interactions with what they perceived to be "ideal" residents; those who fit the stereotype of a nursing home resident, such as older, pleasant, and dependent. The perceived "ideal" residents varied by gender. Generally, female residents were expected to be more independent and at times viewed negatively when requesting assistance.

INTERVENTIONS ADOPTING BODY-MIND-SPIRIT MODEL TO IMPROVE THE HOLISTIC HEALTH OF OLDER ADULTS: A SYSTEMATIC REVIEW

Xinyue Hu,¹ Tongtong Li,² and Iris Chi,³ 1. *University of California, Los Angeles, Los Angeles, California, United States*, 2. *University of Southern California, Arcadia, California, United States*, 3. *University of Southern California, University of Southern California, California, United States*

This systematic review aims to summarize 5 key information from non-pharmaceutical intervention studies which adopt Body-Mind-Spirit (BMS) model for older adults: (1) definition of BMS, (2) types and formats of the interventions, (3) background and BMS training of the interventionists, (4) activities included in the interventions, and (5) effect of these interventions on the holistic health of older adults. We conducted a systematic search of 9 databases (ProQuest, Web of Science, PsycINFO, PubMed, Cochrane, Wanfang, AIRITI, CADAL, CNKI) for studies published in English or Chinese through May 31, 2021. Inclusion criteria were: (1) Must be empirical studies; (2) Participants must be aged 55 and above; and (3) Must adopt the BMS model or contain BMS in full-text. We found 15 studies (7 RCTs, 1 cluster randomized trial, 3 mixed-method studies, and 4 qualitative studies). Ten studies (66.67%) adopted Chan's BMS model. Thirteen studies (86.67%) adopted in-person group interventions. Only five studies (33.33%) provided BMS training to the interventionists. Six articles (40%) categorized the activities as body-, mind- or spirituality-related. Ten studies (66.67%) reported effectiveness in all 3 dimensions of BMS. Of the 7 RCTs, 5 were rated as medium-quality, and 2 were rated as low-quality according to the Cochrane's Risk of Bias tool. Most interventions based on the BMS model claimed to be effective in improving the holistic health of older adults. In order to improve the internal validity, future RCT studies should be more prudent about the randomization process and adhere to the BMS model when designing the interventions.

INTRODUCING THE ATTITUDES TOWARD TECHNOLOGY LONGITUDINAL AGING STUDY (ATLAS): INITIAL WAVE 1 FINDINGS

Robin Stuart, *Florida State University, Tallahassee, Florida, United States*

Differences between younger and older adults' use and adoption of technology have declined over the past two decades, though the mechanisms behind observed trends are uncertain. Few longitudinal studies have tried to capture detailed changes in technology attitudes, adoption, and usage over time among older adults. This presentation presents newly collected data from the first wave of the Attitudes toward Technology Longitudinal Aging Study (ATLAS), a 5-wave questionnaire-based longitudinal study of older adults' attitudes toward technology and levels of technology use ($N = 88$; Men = 30; Women = 58; Mage = 69.7 years). We present baseline characteristics of Wave 1 and explore predictors of technology use, adoption, and proficiency. Waves 2 through 5 will assess changes in these domains. Wave 1 results replicated previous findings in that older age was associated with lower computer and mobile device proficiency (computer: $r = -.219^*$, $p < .05$, mobile device: $r = -.291^{**}$, $p < .01$). However, there was variability among both types of proficiency (McomputerProf = 27.39, SD = 3.57; MmobileProf = 31.52, SD = 9.21), indicating room for change over time. Both types of proficiency were correlated with level of technology use (computer: $r = -.219^*$, $p < .05$, mobile device: $r = -.572^{***}$, $p < .001$). Taken together, these initial relationships suggest the possibility that future waves will see changes in technology use predicted by changes in age-related differences in technology proficiency and attitudes.

LEVERAGING MEDICAL CLAIMS TO PREDICT LONG-TERM CARE TRANSITIONS AMONG OLDER ADULTS IN THE UNITED STATES

Megan Backhaus,¹ An-Ting Jhuang,¹ Ben Griffith,¹ and Lauren Bangerter,² *1. UnitedHealth Group, Minnetonka, Minnesota, United States, 2. OptumLabs, Eden Prairie, Minnesota, United States*

Most older adults prefer to age in place rather than moving to a long-term care (LTC) facility, but little is known about the factors that predict entry into LTC. This study sought to utilize administrative claims data to understand the predictors of LTC transitions using de-identified claims data from Medicare Advantage members in the UnitedHealth Group Clinical Discovery Database. We investigated LTC transitions of 250,587 adults (Mean age = 77, standard deviation = 7.75) between January 1, 2016 and December 31, 2019. Types of predictors for these transitions include aggregated medical data surrounding chronic conditions and frailty indices, as well as healthcare utilization and demographics in 2016 and 2017. We then fit data of these types to an extreme gradient boosting (XGBoost) model to predict long-term care transitions in 2018 and 2019 (ROCAUC = 0.84, accuracy = 0.84, precision = 0.68, and recall = 0.42). Frailty indicators, such as falls and fractures, mobility problems, dementia, and delirium, as well as osteoporosis are strong predictors of LTC transitions. These findings can be used to design interventions aimed at preventing LTC transitions and enabling older adults to age in place.

LONG-LASTING EFFECTS OF THE PANDEMIC ON OLDER ADULTS' FOOD INSECURITY: THE URGENT NEED FOR ENHANCED SNAP BENEFITS

Lauren Popham,¹ Jane Tavares,² and Marc Cohen,³ *1. National Council on Aging, Arlington, Virginia, United States, 2. LeadingAge LTSS Center @UMass Boston, Boston, Massachusetts, United States, 3. University of Massachusetts Boston, University of Massachusetts Boston, Massachusetts, United States*

Despite the start of COVID-19 pandemic recovery in the U.S., food insecurity remains at elevated levels with 10% of American adults reporting food insecurity nearly three times higher than pre-pandemic (Census Bureau's Household Pulse Survey, June 2021). To gain insight into the long-term impacts of the pandemic on older adults, we examined food insecurity patterns during the last economic recession and the role that the Supplemental Nutrition Assistance Program (SNAP) played in mitigating food insecurity and skipped meals. We analyzed data on adults age 60+ from the Health and Retirement Study, looking at the Great Recession (2008) as a predictor of what to expect in the next decade of pandemic recovery. A key finding was that food insecurity more than doubled among older adults during the Great Recession and remained elevated even 10 years later. Regression analyses showed that SNAP use among older adults weakened the relationship between poverty and food insecurity, but didn't eliminate it—17% of older adults still reported food insecurity two years after enrolling in SNAP. The data indicates that a growing share of older SNAP users' benefits have not kept up with rising food costs. In fact, 85% of beneficiaries had monthly benefit amounts below the USDA "Thrifty Plan" budget. Congress recently passed the American Rescue Plan which increases SNAP benefits temporarily, yet these enhancements are about to run out. This study underscores the need for permanent SNAP enhancements to help prevent long-lasting hunger facing millions of older Americans.

MANAGEMENT CHALLENGES FACED BY ADMINISTRATORS AT DEMENTIA CARE NURSING HOMES IN CHINA

Lin Jiang,¹ Fei Sun,² Robin Bonifas,³ and David Hodge,⁴ *1. The University of Texas Rio Grande Valley, Edinburg, Texas, United States, 2. Michigan State University, East Lansing, Michigan, United States, 3. Indiana State University, Terre Haute, Indiana, United States, 4. Arizona State University, Phoenix, Arizona, United States*

Currently, more than 10 million Chinese older adults have been diagnosed with dementia, a number that is expected to increase as the population in China rapidly ages. Yet, little research exists on dementia care in Chinese long-term care facilities. Our research addresses this gap in the knowledge-base by examining the challenges nursing home directors encounter as well as the coping strategies they employ to deal with these challenges. Twenty-one facility directors employed by faith-based nursing homes across 14 provinces in China participated in this study. Semi-structured interviews were conducted in respondents' native language via phone or in person. Most respondents reported a religious affiliation, and about half were female and had been facility directors for more than four years. Two researchers fluent in Mandarin and English coded interview transcripts; thematic analysis

was conducted to identify patterns in the data. The results indicated four primary challenges, which pertained to recruiting and retaining nursing staff, funding, lacking support from the government, and conflicts with family members. The coping strategies included obtaining and using external resources such as volunteer visitors, operationalizing personal spiritual beliefs, and providing training to improve skills and empathy among employees. This study contributes to nursing home practice by expanding our knowledge of culturally relevant dementia management strategies in China. Suggestions to address management challenges from a policy and practical perspective include clear and sustainable financial support from the government, staff training, and staff-resident ratio regulations, seeking external resources, and integrating spiritual strategies into problem management and service quality improvement.

MOTIVATION TO LEARN AND MULTILINGUALISM ACROSS THE ADULT LIFE STAGES IN THE U.S.

Shalini Sahoo,¹ Takashi Yamashita,² Roberto Millar,³ and Phyllis Cummins,⁴ 1. *University of Maryland, Baltimore, Hanover, Maryland, United States*, 2. *University of Maryland, Baltimore County, Baltimore, Maryland, United States*, 3. *The Hilltop Institute, Baltimore County, Maryland, United States*, 4. *Miami University, Oxford, Ohio, United States*

Lifelong learning or continuing education over the life course has become necessary to navigate a rapidly changing technological landscape. Motivation to learn (MtL) is essential for facilitating lifelong learning. In the U.S., most of the educational opportunities are available in English. Moreover, little is known about associations between being multilingual and MtL across the life stages. This study analyzed nationally representative data from the 2012/2014/2017 Program for International Assessment of Adult Competencies (PIAAC) restricted use file (RUF). Using a previously established latent MtL construct, structural equation models were estimated by four age groups --- 25-34 (n = 2,310); 35-44 (n = 1,610); 45-54 (n = 1,670); and 55 and older (n = 2,620). Results showed that being multilingual was associated with greater MtL among younger age groups, including age 25-34 (b = 0.20, p = 0.01) and 35-44 (b = 0.28, p < 0.001), after adjusting for the demographic, socioeconomic and health characteristics of individuals. Multilingualism was not associated with MtL among older age groups, including 45-54 (b = 0.06, p = 0.50) and 55 and older (b = 0.13, p = 0.19). Findings suggest that education policies that target younger multilingual adults are likely to be effective while enhancing MtL of monolingual (i.e., English-speaking only) adults seems to be a necessary first step. Yet, a similar approach may not be effective for older adults, arguably due to more diverse life circumstances, educational needs, and learning style preferences. More detailed interpretations of empirical results and theoretical explanations are needed.

MOTIVATIONS AND EXPERIENCES OF OLDER ADULT VOLUNTEERS IN A TELEHEALTH NURSING SIMULATION ACTIVITY

Jennifer Crittenden,¹ and Kayla Thompson,² 1. *University of Maine, University of Maine, Maine, United States*, 2. *University of Maine, Bangor, Maine, United States*

The COVID-19 pandemic has posed challenges to safely engaging older adults in volunteer activities. This research explored a unique partnership between a Retired Senior and Volunteer Program (RSVP) and a school of nursing to administer a telehealth virtual simulation training for nurse practitioner students. Semi-structured interviews were carried out with nursing simulation coordinators and volunteers after the telehealth simulation exercise. The purpose of this research was to identify principles of successful virtual volunteer engagement for telehealth simulations. This initial pilot study encompassed debriefing interviews with volunteers (N = 3) and interviews with simulation coordinators (N = 2). Three major themes emerged within the response coding: 1) the benefits of virtual simulation volunteering, 2) technology as a facilitating factor and challenge, and 3) unique volunteer management considerations. Both volunteers and coordinators noted that volunteers derived positive emotional benefits and new insights from their participation. Coordinators discussed the “authenticity” factor that older adults brought to the simulation experience as a benefit to engaging older adult volunteers. Technology sub-themes included accessibility considerations, experience with the online format, and other logistical considerations in conducting telehealth simulation. Volunteer management sub-themes encompassed volunteer skills and motivations, the perceived successful aspects of training, and improvements for future simulations. Volunteers discussed an interest and connection to healthcare and education as a motivating factor for their participation in the telehealth simulation. This small scale pilot research will be expanded through future simulation activities to continue to identify principles of practice for engaging older adults in virtual volunteerism.

NATIONAL FAMILY CAREGIVER SUPPORT PROGRAM PARTICIPANTS' RECOMMENDATIONS TO BOOST CAREGIVER SUPPORTS

Heather Menne,¹ Natalie Mulmule,² Angela Gasdaska,² Emily Costilow,² and Kristen Robinson,³ 1. *RTI International, Washington, District of Columbia, United States*, 2. *RTI International, RTI International, North Carolina, United States*, 3. *DLH/SSS, Silver Spring, Maryland, United States*

For more than 20 years, family caregivers have been supported through the National Family Caregiver Support Program (NFCSP) of the Older Americans Act (Title III). The NFCSP provides information to caregivers about available services; assistance in gaining access to services; counseling, support groups and caregiver training; respite care; and supplemental services. In the 2019 National Survey of Older Americans Act Participants, 1,909 NFCSP caregivers were asked “What recommendations do you have for improving the service?” The resulting 748 open-ended responses were thematically coded. The thematic analysis yielded six major themes: Additional Resources, Staffing, Communication, Care Coordination, Quality of Services, and Eligibility. Sub-themes were identified for Additional Resources and Staffing. The most common sub-themes for Additional Resources were requests for more help or services (e.g., grocery shopping), increased funding or financial assistance, and more service hours (e.g., overnight or holiday care). The most common sub-theme for Staffing was the need for

consistent staffing due to high turnover of staff. Chi-Squared tests and Fisher's Exact tests indicated that there were no significant associations between any of the recommendation themes and the gender of the caregiver, employment status of the caregiver, or whether the care recipient has Alzheimer's or dementia. Many of the themes align with results from a recent RAISE Family Caregiving Advisory Council Report. Recommendations from both sets of findings indicate ways that programs, services, and policies can be enhanced to support the needs of care recipients and caregivers.

NEPALI OLDER ADULTS WITH PRE-EXISTING CONDITIONS AND THEIR HEALTHCARE ACCESS AMID COVID-19 PANDEMIC

Aman Shrestha,¹ Saruna Ghimire,¹ Bunsu Chapadia,¹ Uday Narayan Yadav,² Sabuj Kanti Mistry,³ Om Prakash Yadav,⁴ and Mark Fort Harris,³ *1. Miami University, Oxford, Ohio, United States, 2. University of New South Wales, SYDNEY, New South Wales, Australia, 3. University of New South Wales, Kensington, New South Wales, Australia, 4. Ministry of Health and Population, Kathmandu, Bagmati, Nepal*

COVID-19 has greatly impacted older adults with pre-existing non-communicable conditions (hereafter called pre-existing conditions) in terms of their access to essential healthcare services. Based on the theory of vertical health equity, this study investigated access to healthcare by Nepali older adults with pre-existing conditions during the COVID-19 pandemic. A cross-sectional study surveyed 847 randomly selected older adults (≥60 years) in three districts of eastern Nepal. Survey questionnaire, administered by trained community health workers, collected information on participants reported difficulty obtaining routine care and medications during the pandemic, in addition to questions on demographics, socioeconomic factors, and pre-existing conditions. Cumulative scores for pre-existing conditions were recorded as no pre-existing condition, single condition, and multimorbidity for the analyses. Chi-square tests and binary logistic regressions determined inferences. Nearly two-thirds of the participants had a pre-existing condition (43.8% single condition and 22.8% multimorbid) and reported experiencing difficulty obtaining routine care (52.8%) and medications (13.5%). Participants with single (OR: 3.06, 95%CI: 2.17-4.32) and multimorbid (OR: 5.62, 95%CI: 3.63-8.71) conditions had three and five-fold increased odds of experiencing difficulty accessing routine care. Findings were similar for difficulty obtaining medication (OR single: 3.12, 95%CI: 1.71-5.69; OR multimorbid: 3.98, 95%CI: 2.01-7.87) where odds were greater than three-folds. Older adults with pre-existing conditions in Nepal, who require routine medical care and medication, faced significant difficulties obtaining them during the pandemic, which may lead to deterioration in their pre-existing conditions. Public health emergency preparedness should incorporate plans for both managing the emergency and providing continuing care.

NUTRITIONAL RISK AND HEALTH-RELATED QUALITY OF LIFE IN OLDER ADULTS AGING WITH HIV

Nicole Viviano,¹ Ann Gruber-Baldini,² Sarah Schmalzle,³ Kristen Stafford,³ Sarah Chard,⁴ Kareshma Mohanty,³ Elizabeth Parker,³ and Uzoamaka Eke,³ *1. University of Maryland, Baltimore, Gaithersburg, Maryland, United*

States, 2. University of Maryland School of Medicine, Baltimore, Maryland, United States, 3. University of Maryland School of Medicine, Baltimore, Maryland, United States, 4. UMBC, Baltimore, Maryland, United States

Due to antiretroviral treatment success, individuals with HIV are living longer. People aging with HIV (PAWH, 50+) may be more likely to experience nutritional risk compared to their HIV-negative counterparts due to biopsychosocial factors. The DETERMINE checklist measure accounts for social and economic factors as well as aspects of the aging process that are not typically considered when examining nutritional risk and are important for PAWH. The current study examined nutritional risk and health-related quality of life (HRQoL) in PAWH using the DETERMINE checklist and PROMIS t-scores (mental and physical HRQoL) through secondary analyses of 158 participants in the Strengthening Therapeutic Resources in Older patients aging with HIV (STRONG) study. DETERMINE nutritional risk scores (0-21) were separated into 4 groups (low-risk [0-2, n=13], moderate-risk [3-5, n=28], high-risk [6-12, n=78], very high-risk [13-21, n=39]). The sample was 55% male, 94% Black/African American and had a mean age=59 (SD=5.5). Most of the sample (74%) were at high or very high nutritional risk and low HRQoL t-score: physical M=43.7 (SD=9.5), and mental M=45.7 (SD=10.1). Mental and physical HRQoL were significantly ($p<.001$) associated with nutritional risk group as tested through linear regressions. Means were as follows: physical HRQoL low-risk M=53.4 (SD=10.6), moderate-risk M=47.4 (SD=8.9), high-risk M=43.5 (SD=8.1), very high-risk M=38.4 (SD=8.9); mental HRQoL low-risk M=54.0 (SD=8.9), moderate-risk M=49.1 (SD=7.9), high-risk M=46.1 (SD=9.5), and very high-risk M=39.5 (SD=9.7). These associations remained significant after controlling for age and sex. Higher nutritional risk as measured by the DETERMINE checklist in PAWH was associated with poorer physical and mental HRQoL.

OLDER ADULTS PLACE GREATER IMPORTANCE ON A PURPOSEFUL RETIREMENT

Rachel Best,¹ Gabrielle Pfund,² M. Teresa Cardador,³ Victor Strecher,⁴ and Patrick Hill,² *1. Yeshiva University, Bronx, New York, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States, 3. University of Illinois at Urbana-Champaign, Champaign, Illinois, United States, 4. University of Michigan, Ann Arbor, Michigan, United States*

Sense of purpose is associated with desirable health and well-being measures in older adults. Unfortunately, existing research points to complexity in the connection between purpose and retirement: some but not all people decline in sense of purpose following retirement, and some view it as nonessential to maintain a purpose specifically during retirement. These findings suggest there may be individual differences both in the importance placed on being purposeful specifically during retirement, and that there may be a discrepancy in purpose importance before retirement and during retirement. In this study, we examined whether perceived purpose importance correlates with age and personality, as well as working status. Data were collected from a U.S sample (N = 2,009), aged 18-93 (M = 48.51). Participants completed a survey assessing the Big Five personality traits and were asked to rate the importance of purpose before

and after retirement. Findings suggest that, overall, people believe it was important to have a purpose and direction during retirement ($M = 3.86$). Perceived purpose importance during retirement was greater among older, conscientious, and less neurotic adults, but working status did not appear to play a role. Moreover, when comparing perceptions of purpose importance before and during retirement, age was the distinguishing factor differentiating who perceives during-retirement purpose as more important than before-retirement purpose, such that older adults placed greater importance on sense of purpose during retirement. Results indicate that older adults do value having a purpose during retirement, suggesting that purpose-focused interventions may be well-received by this population.

ORAL HEALTH FOR OLDER ADULTS: POLICY BARRIERS AND OPPORTUNITIES

Stephanie de Sam Lazaro,¹ Anchee Nitschke Durben,¹ and Juliette Kline,² 1. *St. Catherine University, Saint Paul, Minnesota, United States*, 2. *St. Catherine University, St. Paul, Minnesota, United States*

Tooth decay and gum disease are two of the most common chronic health conditions in the United States, are reversible and preventable, and impact approximately 68% of older adults nationwide (CDC, 2021; World Health Organization, 2020). While the Affordable Care Act added provisions to health prevention services, oral health prevention coverage was only included for children, leaving many adults and older adults without coverage (Nasseh & Vujicic, 2017). The research team used a rapid review process using 17 key search term combinations to identify literature in three medical databases (PubMed, CINAHL, and Consumer Health Complete) to identify system and policy level barriers and opportunities to address oral health equity issues for older adults in the United States. 40 articles met inclusion criteria for thematic analysis. Findings revealed three barrier categories: 1) poor oral health literacy of patients and health care providers, 2) reimbursement variability contributing to access and utilization barriers, 3) workforce and scope of practice variability. In addition, four opportunity categories were identified: 1) community-based oral health programming for older adults, 2) new reimbursement models, 3) medical-dental collaborations, and 4) policy and practice act updates. The COVID-19 public health crisis has impacted the implementation of some system and policy level opportunities. However, new health care initiatives specific to Medicare in discussion at the national level provide an opportunity to make some headway on the policy updates needed to address the oral health of older Americans. Findings and implications will be shared with the audience.

PAID CARE SERVICES AND TRANSITIONING OUT OF THE COMMUNITY AMONG DIVERSE OLDER ADULTS WITH DEMENTIA

Maria Roche-Dean,¹ Sol Baik,² Heehyul Moon,³ Norma Coe,⁴ Anna Oh,⁵ and Laura Zahodne,⁶ 1. *Western Michigan University, Battle Creek, Michigan, United States*, 2. *University of Maryland School of Social Work, Baltimore, Maryland, United States*, 3. *University of Louisville, University of Louisville, Kentucky, United States*, 4. *University of Pennsylvania, Philadelphia, Pennsylvania, United States*,

5. *San Francisco VA Health Care System, San Francisco, California, United States*, 6. *Clinical Science, Ann Arbor, Michigan, United States*

Objectives: Paid care provided in the home or through community organizations includes important support services for older adults with dementia such as cleaning and personal care assistance. These services could delay the transition to long-term care, but access may differ across sociodemographic groups. This study examined the relationship between paid care and transitioning out of the community among diverse older adults with dementia. Methods: Using data from 303 participants (29.4% Black) with probable dementia in the National Health and Aging Trends Study (2011-2019), subdistribution hazard models estimated the association between receiving paid care at baseline and the probability of transitioning out of the community over the next eight years. Covariate selection was guided by the Andersen model of healthcare utilization. Results: Paid care was associated with lower risk of transitioning out of the community (SHR = 0.70, 95% CI [0.50, 0.98]). This effect was similar after controlling for predisposing factors and most prominent after controlling for enabling and need for services factors (SHR = 0.63, 95% CI [0.42, 0.94]) and was only evident among Whites. There were no racial differences in the use of paid care, but Black participants were less likely to transition out of the community than Whites despite evidencing greater care needs. Discussion: Paid care services may help delay transitions out of the community. Future research should seek to explain racial differences in access to and/or preferences for home-based, community-based, and residential care.

PASSIVE INFRARED MOTION SENSORS IMPROVED THE DETECTION ACCURACY OF NOCTURNAL AGITATION

Wan-Tai Au-Yeung, Lyndsey Miller, Zachary Beattie, and Jeffrey Kaye, *Oregon Health & Science University, Portland, Oregon, United States*

Actigraphy has been used to detect agitation in persons with dementia, although this technology must be worn by participants. Another promising sensing methodology is passive infrared (PIR) motion, which provides continuous, low-cost, and unobtrusive data, and may also improve the detection of agitated periods. Using data from the MODERATE (Monitoring Dementia-Related Agitation Using Technology Evaluation) study, we compared the predictive value of detecting agitation in a male participant, who was 64 years old with Alzheimer's disease (AD), living in a memory care unit, and monitored with actigraphy on his wrist and four PIR motion sensors within his living quarters. The participant's medical record indicated that he experienced agitation during 17 nights over 96 consecutive days. 929,037 data points were captured for analysis. From each night, the features extracted from the actigraphy wearable included total and standard deviation of activity counts, activity counts in the most and the least active hours, and median activity counts in one hour. Features extracted from the PIR motion sensors included dwell durations in the areas around bed, sofa, front door and bathroom, and the number of transitions between these areas. Using logistic regression to predict agitated periods, comparable classification

performances were achieved using these two sets of features (AUC = 0.74 for wearable and AUC = 0.71 for PIR motion sensors). When these two sets of features were combined, the classification performance showed notable improvement (AUC = 0.83). This study points to the value of utilizing PIR motion sensors for detecting dementia-related agitation.

PATHWAYS TO REDUCED OVERNIGHT HOSPITALIZATIONS: EVALUATING 62 PHYSICAL, BEHAVIORAL, AND PSYCHOSOCIAL FACTORS

Jean Oh,¹ Julia Nakamura,² and Eric Kim,¹ 1. *University of British Columbia, Vancouver, British Columbia, Canada,* 2. *University of British Columbia, University of British Columbia/Vancouver, British Columbia, Canada*

As healthcare costs rise steadily and rapidly, researchers and policymakers are increasingly interested in reducing healthcare utilization costs. Growing evidence documents many factors that may influence healthcare utilization; however, less is known about how changes in candidate predictors influence subsequent healthcare utilization. Using data from 11,374 participants in the Health and Retirement Study (HRS)—a diverse, longitudinal, and nationally representative sample of older adults in the United States, we evaluated a large range of candidate predictors of overnight hospitalizations. Using generalized linear regression models with a lagged exposure-wide approach, we evaluated if changes in 62 predictors over four-years (between t0;2006/2008 and t1;2010/2012) were associated with subsequent hospitalizations during the two years prior to t2 (2012-2014 (Cohort A) or 2014-2016 (Cohort B)). After adjustment for a rich set of baseline covariates, changes in some health behaviors (e.g., frequent physical activity), physical health conditions (e.g., no physical functioning limitations), and psychosocial factors (e.g., higher purpose in life, lower anxiety, more volunteering) were associated with decreased hospitalizations four years later. However, there was little evidence that other factors (e.g. smoking, obesity) were associated with subsequent hospitalizations. Notably, some psychosocial factors had effect sizes as large as some physical health conditions. Several indicators of physical health, health behaviors, and psychosocial well-being may predict subsequent hospitalizations, and these factors may be novel targets for interventions and policies aiming to reduce healthcare costs in older adults.

PERSONAL AND ENVIRONMENTAL CHALLENGES OF AGING IN PLACE WITH LONG-TERM MOBILITY DISABILITIES

Widya Ramadhani,¹ and Wendy Rogers,² 1. *University of Illinois Urbana-Champaign, Urbana, Illinois, United States,* 2. *University of Illinois Urbana-Champaign, Champaign, Illinois, United States*

Maintaining independence while aging in place at home requires support, especially for older adults aging with long-term mobility disabilities. As age-related changes progress, individuals with long-term mobility disabilities experience more challenges engaging with daily living activities (ADLs) and instrumental activities of daily living (IADLs). To understand the activity challenges of these older adults, we analyzed the interview data from the Aging Concerns,

Challenges, and Everyday Solution Strategies (ACCESS) study, a comprehensive user needs assessment of 60 older adults who have had mobility disabilities for at least ten years (Koon et al. 2019). We selected interview data that focused on the conduct of ten activities at home: bathing, dressing, moving around, toileting, transferring, doing hobbies, housekeeping, home maintenance, managing diet and nutrition, and caring for others. This archival study used the coding schemes from the ACCESS study that were developed using both conceptual- and data-driven approaches (Koon et al., 2019). The ecological theory of adaptation and aging (Nahemow and Lawton, 1973) was the underlying framework to identify the challenges related to older adults' functional capacity (personal) and physical environmental barriers (environmental). We identified five main challenges: physical strength, general health limitations, mobility limitations, physical access, and transferring. Older adults' responses to overcoming the challenges involved personal, environmental, and person-environment interaction strategies. This study provides insights into the relationship between the source of environmental barriers and personal coping strategies to guide the design of appropriate aging in place supports for older adults with mobility disabilities.

PREDICTORS OF FOOD INSECURITY BEFORE AND DURING COVID-19 AMONG MIDDLE-AGED AND OLDER ADULTS

Jianjia Cheng,¹ and Emily Nicklett,² 1. *School of Public Health, Ann Arbor, Michigan, United States,* 2. *The University of Texas at San Antonio, San Antonio, Texas, United States*

The indirect impact of COVID-19 on food security of middle aged and older adults is not well understood. This study examines changes in risk factors for food security from 2018-2020 in a population-based sample. Using data from the Health and Retirement Study (2018 and 2020 waves), we utilized generalized estimating equations (GEE) with repeated measures to examine factors associated with food insecurity among US adults aged 50 and older (n=3170) before COVID-19 and since COVID-19. The prevalence of food insecurity doubled from 2018 (4.83%) to 2020 (9.54%). In multivariate analyses, the population-averaged odds of experiencing food insecurity was 81% higher in 2020 compared to 2018. Other factors significantly associated with higher odds of food insecurity included being female (OR: 1.29), Black (OR: 1.46), lowest quintile for wealth (OR: 1.82), not working due to a disability (OR: 3.29), renting (OR: 2.04), greater IADL limitations (OR: 1.32), and greater number of chronic illness comorbidities (OR: 1.14). Factors significantly associated with lower odds of food insecurity included older age (65-74: OR: 0.73; 75+: OR: 0.56) and being above the median income level (OR: 0.47). Partnership status, education level, and ADL limitations were not significantly associated with the population-averaged odds of experiencing food insecurity. This study identified factors related to food insecurity among a community-dwelling sample of middle aged and older adults in the U.S. Future research should examine the impact of policies and intervention strategies to address the disproportionate impact of COVID-19 on populations at increased risk of experiencing food insecurity.

PREDICTORS OF POSITIVE OR NEGATIVE REACTIONS TO LEARNING ALZHEIMER'S BIOMARKER RESULTS

Claire Erickson,¹ Nate Chin,² Erin Jonaitis,² Fred Ketchum,² Carey Gleason,² and Lindsay Clark,¹ 1. *University of Wisconsin-Madison, Madison, Wisconsin, United States*, 2. *UW Madison, Madison, Wisconsin, United States*

With improved detection of Alzheimer's disease and biomarker accessibility, more adults with no or mild symptoms may learn their AD biomarker results. Yet, potential psychosocial impact of learning AD biomarkers is not well understood. In a phone survey, we assessed potential reactions after learning about a hypothetical positive AD biomarker result. Data were collected from cognitively healthy participants (n=334, mean age=64.8±7.7) enrolled in longitudinal AD studies. Exploratory factor analysis identified five latent factors following a hypothetical positive biomarker result: advanced care planning, lifestyle changes to reduce dementia risk factors, psychological distress, subjective cognitive complaints, and stigma. Using linear regression, we found that predictors of potential pessimistic reactions (distress, cognitive complaints, stigma) included higher trust in research (Distress:b:0.04, p:0.04), no dementia family history (Stigma:b:-0.30,p:0.04), poorer memory self-rating (Cognitive complaints:b:-0.19,p:0.02), and Black racial identity (Cognitive complaints:b:0.30,p:0.02, Stigma:b:0.40,p:0.003). Predictors of potential optimistic reactions (advanced care planning, lifestyle changes) included more trust in research (Planning:b:0.07,p<0.0001) and Black racial identity (Planning:b:0.38,p:0.003), as well as younger age (Lifestyle:b:-0.02,p:0.02) and belief in AD controllability (Planning:b:0.22,p:0.003, Lifestyle:b:0.23,p:0.002). Concern about developing AD was associated with increased likelihood of all potential reactions. While AD concern associates with optimistic and pessimistic potential reactions, specific factors of family history, racial identity, trust, belief in AD controllability, and memory rating differentially predict each of the potential outcomes of learning AD biomarker results. These findings may help target education efforts to prepare and reduce risk of negative reactions for cognitively healthy adults who learn their AD biomarker results.

PROTECTION AGAINST APOE4-ASSOCIATED AGING PHENOTYPES WITH A LONGEVITY-PROMOTING INTERVENTION

Cassandra McGill,¹ Amy Christensen,² Wenjie Qian,² Caleb Finch,³ Berenice Benayoun,² and Christian Pike,² 1. *University of Southern California, Gardena, California, United States*, 2. *University of Southern California, University of Southern California, California, United States*, 3. *University of Southern California, Los Angeles, California, United States*

Two of the primary risk factors for late onset Alzheimer's Disease (AD) are aging and APOE genotype. While the causal relationship between aging and AD is not well defined, there are strong leads from shared phenotypes such as decreased metabolic function and increased inflammation. APOE genotype may be linked to AD phenotypes through the regulation of aging processes. The NIA Interventions Testing Program (ITP) recently found that 17 α -estradiol (17 α E2) treatment increases rodent lifespan. Since 17 α E2 acts upon systemic and neural pathways associated with AD pathology,

we propose that 17 α E2 may be a pleiotropic intervention strategy. Further, because APOE4 is associated with a senescent phenotype, 17 α E2 may have APOE genotype-specific effects. Using 10-month-old APOE3 or APOE4 targeted replacement male mice maintained on normal chow with and without 14.4 ppm 17 α E2 for 20 weeks, our initial results indicate genotype differences in the efficacy of 17 α E2 across multiple outcomes. APOE4 mice exhibited an aged phenotype compared to APOE3, with APOE4 mice having a higher frailty index; however, 17 α E2 treatment reduced the frailty index most strongly in APOE4 mice. APOE4 mice were impaired across multiple metabolic measures including body weight, plasma leptin, and hepatic steatosis. 17 α E2 significantly attenuated the APOE4 metabolic phenotype. These data confirm and extend prior findings that APOE4 is linked to progeroid effects both peripheral and neural outcomes associated with AD risk. Importantly, 17 α E2 significantly improved a range of measures, but showed the strongest effects in the APOE4 genotype. This research was funded by the Cure Alzheimer's Fund.

RACIAL DISPARITIES IN HOSPITALIZATION EXPENDITURES OF OLDER ADULTS IN SINGAPORE

Cynthia Chen,¹ Xueying Guo,² Hwee Lin Wee,² and Kelvin Bryan Tan,³ 1. *National University of Singapore, Singapore*, 2. *National University of Singapore, Singapore*, 3. *Ministry of Health, Singapore, Singapore*

The World Population Prospects 2019 reports that the proportion of people who aged 65 and above takes up 9 per cent globally in 2019, reaching up to 16 per cent by 2050. Asia has the fastest rise: from 1 in 9 people aged 65 and above to 1 in 4 in 2050. Rapid growth in older adults has strong implications for diseases and healthcare expenditure. For Singapore, the transition from 'ageing society' (7% seniors) in 1999 to 'super-aged society' (20% seniors) in 2026 is projected to take 27 years, much faster than Japan's 36 years. We used the Singapore Multi-Ethnic Cohort (MEC) of 14,465 subjects aged 21 to 94, and the Future Elderly Model (FEM) microsimulation model to project disease burden and hospitalization expenditures to 2050. We found that Chinese females had the highest life expectancy of 86.0 years, followed by Indian and Malay females with 80.4 and 75.6 years respectively. In all racial groups, women lived longer than men by 5-7 years. Cumulative hospitalization expenditures of older adults aged 51+ was US\$69,500 for Chinese, US\$67,600 for Malays and US\$86,100 for Indians; US\$71,200 for males and US\$70,700 for females. The increased hospitalization spending for all three ethnic groups was due to the underlying manifestation of chronic diseases, including diabetes, hypertension, heart disease and stroke. Variations in environmental risk factors such as diet, cigarette smoking and physical activity across ethnic groups may contribute to racial differences in chronic diseases and disability. Therefore, targeted interventions are needed to reduce racial disparities.

RACIAL SEGREGATION AND MENTAL HEALTH SERVICE USE BY OLDER ADULTS

Kyeongmo Kim,¹ and Denise Burnette,² 1. *Virginia Commonwealth University, Henrico, Virginia, United States*, 2. *Virginia Commonwealth University, Virginia Commonwealth University, Virginia, United States*

Older adults living in racially segregated neighborhoods often lack access to mental health care. This study assessed the role of racial segregation in mental health service use and examined

whether the relationship between segregation and mental health service use differs by race/ethnicity. We linked residential segregation data from the National Neighborhood Change Database to the 2015 Medical Expenditure Panel Survey. The sample included 4,023 adults aged 65 and older. We measured mental health service use as visit(s) to a mental health professional and/or use of prescribed medication for mental health (1=yes, 0=no) during the past year. Residential segregation was assessed using a combined measure of isolation (level of interaction with the same racial and ethnic group members) and dissimilarity (evenness of distribution of racial groups). Indices ranged from 0 (integrated) to 1 (segregated). We adjusted for age, sex, race/ethnicity, marital status, education, income, attitude toward health care, health insurance, and mental health status. Multiple logistic regression analyses showed that older adults living in more segregated counties were less likely to use a mental health service than those living in more integrated counties (OR=0.77, $p=.04$). The relationship did not differ by race/ethnicity. As expected, Blacks and Hispanics underused mental health services compared to Whites. The findings highlight that racial segregation limits access to mental health care. Practitioners and policy-makers should identify mental health needs and service use patterns to target services effectively and efficiently. Future research should explore the intersection of income and mental health care resources in segregated neighborhoods.

RELATIONSHIP QUALITY PREDICTS ADVANCE CARE PLANNING ENGAGEMENT IN FAMILIES EXPERIENCING COGNITIVE DECLINE

Rachel Bloom,¹ and Celia Fisher,² 1. *Fordham University, New York, New York, United States*, 2. *Fordham University, Bronx, New York, United States*

Although clinical guidelines recommend that people showing signs of cognitive decline engage in Advance Care Planning (ACP) while they still have decision-making capacity, too often this opportunity to clarify values and treatment preferences is missed among patients and their families. In reflection of the paucity of empirical data on factors influencing how this planning process begins for families experiencing cognitive decline, this study explored facilitators and barriers to ACP among adult children of parents showing signs of early- to mid-stage dementia, with a particular focus on relationship quality. Among this sample ($N = 315$), relationship quality positively and significantly predicted advance care planning engagement ($r = .349$, $p < .001$). Financial burden weakly and positively predicted ACP engagement ($r = .123$, $p < .05$), while both psychological burden ($-.614$, $p < .001$) and financial burden ($-.290$, $p < .001$) negatively and significantly predicted relationship quality. This study validates the use of the ACP Engagement Survey (ACPES) adapted for surrogates among adult children of people experiencing cognitive decline and contributes to a scarce literature on the impact of relationship quality on ACP engagement.

RELYING ON MYSELF: THE LIVED EXPERIENCE OF BEING AT RISK FOR FALLING IN THE HOSPITAL AMONG OLDER ADULTS

Hanne Dolan, Cindy Rishel, Jessica Rainbow, and Ruth Taylor-Piliae, *University of Arizona, University of Arizona, Arizona, United States*

Inpatient falls are a persistent problem and despite research efforts during the last decade, inpatient fall rates

have not significantly decreased. Older adults have an estimated 50% greater inpatient fall rate than younger adults. How older adults perceive their own fall risk affects their adherence to fall prevention recommendations. The aim of this phenomenological study was to gain a deeper understanding of the lived experiences of being at risk for falling in the hospital among older adults aged 65 years and older ($N=9$). Participants (female=55%, age range=67 – 86) were interviewed twice using video conferencing within two weeks of hospital discharge. The audio-recorded interviews were transcribed, and then analyzed using van Manen's interpretive phenomenological method. The Health Belief Model expanded with the concepts of independence, fear of falling, embarrassment, dignity, and positivity effect served as the theoretical framework. Five major interpretive themes emerged: Relying on Myself, Managing Balance Problems in an Unfamiliar Environment, Struggling to Maintain Identity, Following the Hospital Rules, and Maintaining Dignity in the Relationships with Nursing Staff. These themes describe how the participants thoughtfully planned their mobilization to avoid falls. This process was influenced by their struggling to remain independent, following the hospital fall prevention rules out of politeness, and experiencing both positive and negative relationships with nursing staff. Hospitalized older adults employed their self-efficacy to manage balance problems in the hospital. These findings have not been previously documented in the literature. Fall prevention interventions supporting hospitalized older adults' self-management of fall risk are needed.

RESEARCH CONCERNING THE CARE PLANNING BY CARE MANAGERS IN HOME-BASED COMMUNITY CARE SUPPORT CENTERS OF JAPAN

Takako Ayabe,¹ and Shinichi OKADA,² 1. *BAIKA Women's university, Ibaraki, Osaka, Japan*, 2. *Osaka City University, Osaka, Osaka, Japan*

The research was conducted between February 9 and 28, 2017. The care management centers were randomly selected from the national list of the centers. The data were collected by self-administered questionnaires mailed to the care managers at 500 care management centers in six prefectures in the Kinki area of Japan. The independent variables were gender, age, experience years of care managers and/or social workers, Clients' Physical and Mental conditions (CPM), Client's Lifestyle (CL), Physical and Mental conditions of the Caregivers (PMC), and Human and Financial resources for Clients and their Caregivers (HFCC). The dependent variables were the categorized contents in the care planning. They included the Approach for exploring Client's needs (AC), Coordination among Care services within the program in accordance with the needs of client (CC), Coordination among Formal services and informal supports without the program in accordance with the needs of clients (CF). We examined the relationships between the dependent and independent variables by using the Structural Equation Modeling. The results indicated that the goodness of the fit indices was acceptable, and we retained the models. In correlational analyses, AC was significantly correlated with PMC ($p<.01$), CPM ($p<.05$), and CL ($p<.001$). CC was significantly correlated with PMC ($p<.001$), CPM ($p<.001$), and CL ($p<.01$). CF was significantly correlated with PMC ($p<.05$), HFCC ($p<.05$), and CL ($p<.05$). In conclusion, our findings suggest

that care managers should recognize that information concerning the clients' and their caregivers' conditions is significant in making appropriate care planning for the clients and their caregivers.

RESPIRE SERVICE USE AMONG DEMENTIA AND NONDEMENTIA CAREGIVERS: FINDINGS FROM THE CAREGIVING IN THE U.S. 2015 SURVEY

Yura Lee,¹ Wonchan Choi,² and Min Sook Park,² 1. *Helen Bader School of Social Welfare, Milwaukee, Wisconsin, United States*, 2. *University of Wisconsin-Milwaukee, University of Wisconsin-Milwaukee/Milwaukee, Wisconsin, United States*

Caring for persons with dementia places a significant physical, emotional, and financial burden on caregivers. Although dementia caregivers may be exposed to more challenging caregiving environment than caregivers of those with other chronic conditions, little is known about how specific factors related to respite service use differ between dementia and nondementia caregivers. Thus, this study first examined factors related to respite service use among caregivers and further tested the moderating effect of dementia caregiver status in these relationships using nationally representative U.S. data. Logistic regression analyses were conducted among 1,203 caregivers (276 dementia and 927 nondementia caregivers) from the national Caregiving in the U.S. 2015 data. Caregivers' race and ethnicity as a predisposing factor, caregivers' self-rated health as an enabling factor, and care recipients' living arrangement and functional limitations as need factors were significantly related to respite service use among caregivers. Moreover, dementia caregiver status moderated the association between enabling factors (i.e., household income, work status, and self-rated health) and respite service use. Our findings imply that dementia caregivers may be more in need of respite service use than nondementia caregivers when they have limited enabling factors (e.g., lower household income, nonworking status, poorer health). Policy and practice efforts that specifically support enabling factors are suggested to promote more respite service use among dementia caregivers.

ROLE OF NATIVITY IN END OF LIFE CARE PLANNING

Kay Thwe Kyaw,¹ Elizabeth Helzner,² Carl Rosenberg,³ and Michael Reinhardt,³ 1. *SUNY Downstate Health Sciences University, and NYU Grossman School of Medicine, Peekskill, New York, United States*, 2. *SUNY Downstate Health Sciences University, Brroklyn, New York, United States*, 3. *SUNY Downstate Health Sciences University, Brooklyn, New York, United States*

Given the rapidly aging population, optimal end-of-life (EOL) consistent with individual wishes is a public health priority. Advanced Care Planning (ACP) involves Advanced Directives (AD) and establishing a Power of Attorney (POA). AD describe EOL Care preferences including options to limit treatment, withhold treatment, provide comfort care, and prolong treatments. Nativity can provide meaningful guidance in decision-making at the end of life. Data from this study came from the Health and Retirement Study, nationally representative longitudinal study of U.S. residents. The sample included 4,015 older adults, 65 and above years of

age who died during study follow-up. Nativity was categorized as U.S born and Foreign born. ACP variables included presence of AD and POA, and EOLC preferences included provide comfort care, limit, withhold, or prolong treatment. Covariates included age, gender, race, marital status, education, and subjective health at baseline. Cox Proportional Hazards (Cox PH) and Weibull Models were used to identify associations between nativity and end of life care. Results: Compared to U.S born, Foreign born participants were less likely to have POA (HR: 0.75; 95% CI:0.64-0.89) in Cox PH and POA (HR: 0.63; 95 % CI:0.53-0.75) Weibull models in unadjusted models, limited treatment (HR: 1.58; 95 % CI: 1.2, 2.1), and prolong treatment (HR: 0.23; 95 % CI:0.06-0.99) and Cox PH and (HR: 0.20; 95 % CI: 0.05-0.83) in Weibull modes. Conclusion: There are differences in Advanced Care Planning by nativity. Country of origin should be considered when helping individuals plan for end-of-life care.

ROLES OF SOCIAL ISOLATION AND RURALITY ON FUNCTIONAL LIMITATIONS IN OLDER ADULTS LIVING IN THE US

Kaleigh Ligus,¹ Keith Bellizzi,¹ and Greg Rhee,² 1. *UConn, Storrs, Connecticut, United States*, 2. *UConn, Farmington, Connecticut, United States*

Social isolation is a growing problem among adults aged ≥65. Using 2019 data from the National Health and Aging Trends Study (NHATS) (n=4,603), we examined the associations of social isolation and rurality with functional limitations in US older adults. We hypothesized that rural older adults would report social isolation more than non-rural adults, and social isolation and rurality would have an interaction effect on difficulty in performing activities of daily living (ADLs). Stress buffering theory guided this research suggesting individuals who have greater social connections also have greater coping skills to buffer against health-related stress. We assessed rural and non-rural older adults' social isolation (measured by a composite score of engagement in community activities and social connections) and difficulty in completing ADLs (e.g., difficulty in dressing, bathing, and eating in the past month). Our results supported one of the hypotheses that there were differing levels of social isolation among both rural and non-rural older adults. In both rural and non-rural groups, oldest-old (85+), non-White adults, those with poor health or had multiple comorbidities were significantly isolated or experienced severe isolation. These results support (1) the premise that specific demographic characteristics are associated with social isolation as well as (2) a growing body of research showing rural adults have unique characteristics that are protective against social isolation. Our findings are related to demographic predictors which could help target interventions toward specific at-risk groups. Policymakers and healthcare practitioners should be aware of risks for social isolation and prepare to discuss these issues.

SEDENTARY BEHAVIOR, SLEEP QUALITY, AND SUBJECTIVE MEMORY FUNCTION IN MIDDLE-AGED ADULTS

Yen Chen,¹ Carole Holahan,² and Darla Castelli,² 1. *University of Michigan, Ann Arbor, Michigan*,

United States, 2. *The University of Texas at Austin, Austin, Texas, United States*

While there is evidence that prolonged sedentary behaviors (SB) are associated with poor memory performance, less is known about the effect of SB on subjective memory. Poor subjective memory could be an early symptom of mild cognitive impairment or dementia. Besides SB, sleep quality has been identified as an essential component of cognitive health. Yet little is known about the effects of different types of SB on sleep quality and how such effects could, in turn, affect middle-aged adults' subjective memory. The sample included 306 adults ranging in age from 40 to 60 ($M = 44.42$) from Amazon MTurk. Mediation analysis with PROCESS (Hayes, 2013) was used to examine the mediational path, controlling for demographic variables. Exploratory factor analysis categorized 10 different sedentary activities into Common Engaging SB (e.g., sitting in cars), High Engaging/Leisure SB (e.g., doing hobbies when sitting), and Less Engaging/Passive SB (e.g., watching TV). Common Engaging SB included a variety of behaviors, including transportation, reading, talking on the phone, and socializing. Common Engaging SB had a significant direct effect on sleep quality ($B = 0.19$, $p < .001$) and frequency of forgetting ($B = -1.61$, $p < .001$), and sleep quality had a significant direct effect on frequency of forgetting ($B = -1.90$, $p < .001$). Sleep quality mediated the association between Common Engaging SB and frequency of forgetting (indirect effect = -0.05 , 95% bootstrap CI = -0.09 , -0.02). Reducing sitting time, particularly Common Engaging SB, could be a useful strategy to improve subjective memory functioning.

SELF-REPORTED FRAILITY CONCERNS IN OLDER BREAST CANCER SURVIVORS DURING THE COVID-19 PANDEMIC

Adele Crouch,¹ and Diane Von Ah,² 1. *University of Pennsylvania, Philadelphia, Pennsylvania, United States*, 2. *Indiana University, Indianapolis, Indiana, United States*

Frailty among older adults is common, especially those who have undergone breast cancer treatment; however, we do not know how frailty among this group presented during the COVID-19 pandemic. The purpose of this descriptive, cross-sectional study was to examine self-reported frailty among older breast cancer survivors (BCS) during the pandemic. This IRB-approved study recruited BCS who were at least 1-year post-treatment and 60 years of age or older, via online advertisements (e.g., Dr. Susan Love Foundation). BCS completed demographic and Tilburg Frailty Indicator (TFI) RedCap questionnaires from 11/2020 to 05/2021. The TFI, is a 15-item measure with 3 sub-scales with published cut points indicating frailty: total (5), physical (3), psychological (2), and social (2). Descriptive statistics were used. Older BCS ($n=203$) who were on average 65.5 ($SD=4.7$) years of age, white (93.6%; $n=190$) and had stage II breast cancer at diagnosis (39.9%; $n=81$) participated. The average total ($M=5.4$, $SD=2.5$) and physical ($M=3.2$, $SD=1.5$) frailty scores were above the threshold for frailty. Overall, 58.6% ($n=119$) and 63.1% ($n=128$) scored at or above the threshold on the total and physical sub-scales, respectively. In addition, 78.8% ($n=160$) responded that they 'missed having people around' on the social frailty sub-scale. Research has shown that higher TFI scores (more frailty) are associated

with increased healthcare utilization, poorer quality of life, and even mortality. Thus, frailty among older BCS is an important health concern within the context of the pandemic. Further research is needed to understand the lasting effects of self-reported frailty for BCS including COVID-19 survivors.

SHOULDER FUNCTION AND FATTY INFILTRATION ON MRI IN OLDER ADULTS DURING REHABILITATION FOR ROTATOR CUFF TEAR

Derik Davis,¹ Ranyah Almardawi,² Omer Awan,² Lawrence Lo,³ Sagheer Ahmed,⁴ Shams Jubouri,² and Rao Gullapalli,² 1. *University of Maryland School of Medicine, Ellicott City, Maryland, United States*, 2. *University of Maryland School of Medicine, Baltimore, Maryland, United States*, 3. *Perelman School of Medicine at the University of Pennsylvania, Philadelphia, Pennsylvania, United States*, 4. *Geisel School of Medicine at Dartmouth, Lebanon, New Hampshire, United States*

Rotator cuff tear is highly prevalent in older adults, with supraspinatus tendon tear (STT) the most common. Shoulder rehabilitation is a major treatment strategy, but supraspinatus-muscle-fatty infiltration (FI) and shoulder function in older adults with rotator cuff tear primarily managed by physical therapy (PT) is inadequately documented. We tested the hypothesis that older adults receiving usual-care PT when stratified by supraspinatus tear-status differ in supraspinatus FI [by quantitative Dixon fat fraction (FF) and semi-quantitative Goutallier grade (GG) on MRI] and shoulder function [by the American Shoulder and Elbow Surgeons score (ASES-score)] over time. Longitudinal cohort study (pilot): adults 60-85 years, PT-cohort ($n=15$) and control-cohort ($n=25$). Participants completed both shoulder MRI and ASES survey at baseline and follow-up visits. Kruskal-Wallis test compared within cohort among 3 groups: no tear (no-STT), partial-thickness tear (pt-STT), full-thickness tear (ft-STT). Mann-Whitney U test compared equivalent groups between cohorts. Baseline PT-cohort groups differed for GG ($p=0.033$) [no tear, 0.50 ± 0.50 ; pt-STT, 1.11 ± 0.22 ; ft-STT, 1.50 ± 0.50] without difference in age, BMI, comorbidity, or ASES-score. Baseline control-cohort groups differed for FF ($p=0.034$) [no-tear, $5.77\%\pm 1.16\%$; pt-STT, $7.14\%\pm 6.26\%$; ft-STT, $21.44\%\pm 10.44\%$], without difference in age, BMI, comorbidity, or ASES-score. Baseline no-tear groups for ASES-score ($p=0.049$) differed between cohorts: PT-cohort (58.87 ± 8.21) versus control-cohort (83.98 ± 21.89). Both cohorts showed no difference in Δ -FF or Δ -GG over time. PT-cohort groups differed for Δ -ASES-score over time ($p=0.042$) [no-tear, 16.65 ± 4.69 ; pt-STT, -7.24 ± 0.94 ; ft-STT, 4.48 ± 3.45], but control-cohort groups did not ($p>0.050$). Our results suggest differences exist for supraspinatus FI and self-reported shoulder function among older adults receiving PT for rotator cuff tear when stratified by supraspinatus tear-status.

SIX-MONTH LOWER-LEG SENSORY STIMULATION AUGMENTS NEURAL NETWORK CONNECTIVITY ASSOCIATED WITH IMPROVED GAIT

Chun Liang Hsu,¹ Ikechukwu Iloputaife,² Lars Oddsson,³ Brad Manor,⁴ and Lewis Lipsitz,⁵ 1. *Hinda and Arthur Marcus Institute for Aging Research, Harvard Medical School, Burnaby, British Columbia, Canada*, 2. *Hebrew Senior Life,*

Boston, Massachusetts, United States, 3. RxFunction, Eden Prairie, Minnesota, United States, 4. Hinda and Arthur Marcus Institute for Aging Research, Harvard Medical School, Boston, Massachusetts, United States, 5. Hebrew SeniorLife, Boston, Massachusetts, United States

Foot sole somatosensory impairment associated with peripheral neuropathy (PN) is prevalent and a strong independent risk factor for gait disturbance and falls in older adults. A lower-limb sensory prosthesis providing afferent input related to foot sole pressure distributions via lower-leg vibrotactile stimulation has been demonstrated to improve gait in people with PN. The effects of this device on brain function related to motor control, however, remains equivocal. This study aimed to explore changes in brain network connectivity after six months of daily use of the prosthesis among individuals with diagnosed PN and balance problems. Functional Gait Assessment (FGA) and resting-state functional magnetic resonance imaging were completed before and after the intervention. Preliminary analysis on participants who have completed the study to date (N=5; mean age 76 years) indicated altered connectivity of the sensorimotor network (SMN), frontoparietal network (FPN), and the default mode network (DMN) post-intervention ($Z > 3.11$, unadjusted $p < 0.05$). Participants displayed an average improvement of 5.5 point in the FGA (Minimal Clinically Important Differences > 4 for community-dwelling older adults) that was correlated with connectivity changes (unadjusted $p < 0.05$). Specifically, improved FGA was associated with: 1) increased connectivity between the SMN, cerebellum, and occipital cortex; 2) increased connectivity between the FPN, cerebellum, calcarine and intracalcarine; and 3) decreased connectivity between DMN and intracalcarine. These early findings suggest that long-term use of a lower-limb sensory prosthesis may induce neuroplastic changes in brain network connectivity reflecting enhanced bottom-up sensory-attentional processing and suppression of the DMN that are relevant to gait improvements among older adults with PN.

SOCIAL CONNECTEDNESS, MEALS ON WHEELS SERVICES AND HEALTHCARE UTILIZATION AMONG HIGH-NEED OLDER ADULTS

Sarah Walsh,¹ Jennifer Chubinski,² and France Weaver,²
 1. Eastern Michigan University, Ypsilanti, Michigan, United States, 2. Xavier University, Cincinnati, Ohio, United States

Homebound vulnerable adults 65+ are at an increased risk for social isolation and loneliness. The adverse consequences of loneliness are profound – including increased health care utilization, burden of dementia, chronic diseases, and mortality. Meals on Wheels (MOW) is a familiar source of nutritional support for homebound individuals who wish to stay in their homes and has additional important benefits. A growing body of evidence demonstrates that MOW provides mental and social health benefits beyond nutrition, but less is known about the interplay between MOW, social cohesion, and health services use. This project will address this gap in the literature using data from the 2013-2020 National Health and Aging Trends Study (NHATS), a nationally-representative panel study of 65+ Medicare enrollees. Using matching and longitudinal multivariate techniques, the risks of hospitalization and permanent nursing home entry are compared between MOW users and non-users. Our longitudinal dataset includes

11,266 observations. Of those, 12.8% rely on MOW or other food assistance (N= 1,488) and 16.6% experience low social cohesion (N= 1,936). Some 6.6% of participants are nursing home residents (N= 748) and the 39.1% report an overnight hospital stay in the prior year (N= 4,560). MOW is a comparatively low-cost intervention to help homebound older adults retain their independence and limit costlier healthcare utilization. This work extends our understanding of MOW services beyond simple nutrition benefits to its potential impact on social health.

SOCIAL DETERMINANTS OF HEALTH AMONG OLDER KOREAN IMMIGRANTS IN THE UNITED STATES: A SYSTEMATIC REVIEW

Sojeong Lee,¹ and VICTORIA RIZZO,² 1 School of Social Welfare, University at Albany, SUNY, Albany, New York, United States, 2. University at Albany, SUNY, Albany, New York, United States

The visible impact of the SDoHs on health and behavioral health as well as health disparities among minority populations is heightened due to COVID-19. One group about which little is known in relation to SDoHs is the older Korean immigrant population in the U.S. To examine the impact of SDoHs on the health, mental health, and health care utilization, a systematic review of studies focused on SDoHs for this population was conducted. Using multiple indexing terms, databases were searched for articles published in English between January 1, 2011 and December 2020. Articles were included in the search if they examined social determinants of health of older Korean immigrants defined as foreign-born Koreans aged 60 or older who live in the United States regardless of citizenship or legal immigration status. A total of 1090 articles were identified in the search. A review of abstracts for inclusion criteria resulted in 118 articles for review. Seventy-one articles were excluded during the review process. A total of 47 articles met inclusion criteria and were evaluated. The review revealed that SDoHs, including education level, financial resources, access to health insurance, level of acculturation and level of social support, influenced cognitive status, depressive symptoms, health status and quality of life. These findings validate the need for interventions to address the social care needs of older Korean immigrants and can be used to identify the role of social workers in addressing the SDoHs that result in health disparities for older Korean immigrants.

STIGMA OF DEMENTIA DURING COVID-19: FIRST INSIGHTS FROM A TWITTER STUDY

Juanita-Dawne Bacsu,¹ Megan O'Connell,¹ Alison Chasteen,² and Sarah Fraser on behalf of CCNA's SSI Working Group,³ 1. University of Saskatchewan, Saskatoon, Saskatchewan, Canada, 2. University of Toronto, Toronto, Ontario, Canada, 3. University of Ottawa, Ottawa, Ontario, Canada

Stigma is a critical issue that reduces the quality of life for people living with dementia and their care partners. Despite this knowledge, little research examines stigma of dementia, especially within the context of the COVID-19 pandemic. This presentation aims to: 1) identify the contributing factors of stigma against dementia during the COVID-19 pandemic; and 2) describe actions to challenge stigma of dementia.

Using Twitter data, tweets were compiled with Python's GetOldTweets application from February to September 2020. Search terms included keywords for dementia (e.g., Alzheimer's) and COVID-19 (e.g., coronavirus). From the 20,800 tweets, filters were used to exclude irrelevant tweets. The remaining 5,063 tweets were analyzed by a group of coders with 1,743 tweets identified for further stigma-related coding. The 1,743 tweets were exported to Excel for thematic analysis and divided among 13 coders. Each tweet was coded independently by two reviewers to ensure intercoder reliability (e.g., 86%). Contributing factors of stigma of dementia included: ageism and devaluing the lives of people with dementia (e.g., 'old and dying anyways'); misinformation and false beliefs (e.g., 'COVID-19 vaccine causes dementia'); political dementia-related slander and ridicule (e.g., 'dementia Joe'); and stigma within healthcare and long-term care organizations (e.g., pushing DNR orders). Globally, there is an urgent need for more dementia education and awareness targeted towards the general public, healthcare workers, and policymakers to reduce stigma against people living with dementia. Further research is necessary to explore the contributing factors and interventions to reduce stigma of dementia during the COVID-19 pandemic and beyond.

THE (UN)WILLINGNESS TO KEEP LIVING AT VERY ADVANCED AGES

Oscar Ribeiro,¹ Lia Araujo,² Laetitia Teixeira,³ and Rosa Marina Afonso,⁴ 1. *University of Aveiro, University of Aveiro, Aveiro, Portugal*, 2. *Polytechnic Institute of Viseu, Viseu, Viseu, Portugal*, 3. *ICBAS - University of Porto, ICBAS.UP, Porto, Portugal*, 4. *University of Beira Interior, University of Beira Interior, Castelo Branco, Portugal*

A long life is a general desire that will be reached by more and more people, particularly in developed countries. But the delay of mortality raises important questions about quality of life in the later years. Centenarians have received attention from different disciplines, particularly from demography and genetics, but a psychological approach on whether life at age 100 is perceived as worth living is still very limited. This study explores centenarians' will to live and associated factors in a sample of 121 centenarians (mean age 101 years; SD 1.63 years; 84.3% female), who answered to a questionnaire comprising sociodemographic characteristics, health status, social functioning, and well-being as well as open questions on their will to live and end-of-life issues. Of the total sample, 31.4% expressed willingness to live longer, 30.6% did not, and 38% presented no clear positioning. From the qualitative thematic analysis, annoyance, uselessness, loss of meaning, disconnection, and loneliness were the most common justifications for being reluctant to live longer. Positive valuation of life and good self-rated health, followed by having a confidant and reduced pain frequency, were the reasons for being willing to live longer. From the quantitative analysis, associated factors of will to live include pain frequency, self-rated health, having a friend confidant and valuation of life. This study provides researchers suggestions for further investigation and highlight the importance of inquiring and understanding very old people's values and views on their will to live, future wishes, and meaning in life.

THE DAILY CHALLENGES OF CARING FOR GRANDCHILDREN: A DAILY ANALYSIS OF EMOTIONAL AND PHYSICAL REACTIVITY TO STRESSORS

Elizabeth Hahn Rickenbach, and Janelle Fassi, *Saint Anselm College, Manchester, New Hampshire, United States*

Grandparents are increasingly providing extensive and custodial care for their grandchildren. Many factors have contributed to a societal rise in caregiving among grandparents, including addiction, incarceration, dual-income families, and the cost of childcare. Past work has highlighted positive effects of grandparenting (e.g. reduced dementia risk); however, research is limited that examines the day to day challenges grandparent caregivers experience. The goal of this research was to examine daily experiences of stressors, positive events, physical symptoms, and daily mood of grandparent caregivers. Participants (n=18 grandparent caregivers) filled out a diary survey for five consecutive days that measured daily stressors and positive events. A total of 90 diaries were completed. Stressors were reported on 97.6% of days. Multilevel analysis examining emotional and physical reactivity to daily events showed that, controlling for age and gender, on days when participants reported more stressors than average, they reported higher negative affect ($p=.019$), lower positive affect ($p=.003$) and more physical symptoms ($p=.002$). Positive events were not significantly associated with daily mood or daily physical symptoms. Overall, the findings supported the hypothesis that grandparent caregivers experience emotional and physical reactivity to the daily challenges they experience. Future research should examine resources and supports to reduce the impact of daily stressors, as well as the particular challenges among underrepresented groups, particularly Black and Latino grandparents, who provide disproportionate levels of care for their grandchildren. The current study highlights the potential vulnerability and daily needs for support among grandparents who provide regular and custodial care for their grandchildren.

THE FINANCIAL AND OPERATIONAL EFFECTS OF COVID-19 ON OHIO'S LONG-TERM CARE RESIDENTIAL SETTINGS

Katherine Kennedy,¹ Robert Applebaum,² and Kathryn Brod,³ 1. *LTSS COIN Providence VA Medical Center*, 2. *Miami University, Oxford, Ohio, United States*, 3. *LeadingAge Ohio, Columbus, Ohio, United States*

The COVID-19 pandemic has had a drastic impact on Ohio's long-term care facilities. Yet, months into the crisis, the financial ramifications and workforce shortage were unknown. In partnership with the Scripps Gerontology Center at Miami University, LeadingAge Ohio and the Ohio Health Care Association developed an online survey that was launched in July 2021. Response rates were 46.4% for skilled nursing facilities (SNFs; N=446) and 35.8% for residential care facilities (RCFs; N=287). Core questions compared the first quarters of 2020 and 2021. Declines in operating revenues (-11.7% SNFs; -10% RCFs) and rising labor costs per patient day (17.9% SNFs; 16.1% RCFs) contributed to most providers experiencing a financial loss in the most recent month (78% SNFs; 66% RCFs). The increased

documented use of agency staff is an important finding of this work; 62% of SNFs and 34% of RCFs spent money on agency staff. Despite increases in starting wages, the labor crisis remains severe. As of July 2021, SNFs had an average of 19.51 open positions, of which 9.82 were for state-tested nurse aides and 5.65 were for nurses. RCFs had an average of 8.83 open positions, of which 4.24 were for resident care assistants and 1.89 were for nurses. The challenges faced by the long-term care industry have rightly focused on the deleterious impacts of COVID on residents and staff. But these data also suggest that the financial impacts on the industry are serious and will likely shape access and provision of care in the future.

THE GROWING BURDEN OF INFORMAL CAREGIVERS DURING COVID-19

Stephanie MacLeod, *UnitedHealth Group, United States*

Caregiver burden has negative effects on health outcomes and quality of life. Meanwhile, safety protocols during the COVID-19 pandemic created immediate impacts on informal caregiving with increasing burden on family caregivers. Our primary purpose was to describe the impacts of the pandemic on caregiver burden among informal caregivers, and their sudden shift in roles as a result. This review describes emerging effects on various aspects of health and explores future directions to support informal caregivers. A streamlined search was conducted to fit the scope of this review, with key terms determined to identify relevant publications. Common research databases and mainstream resources were utilized. We focused on research published since March 2020 to align with the timing of the pandemic in the US. Early research suggests that the pandemic has worsened caregiver burden among informal family caregivers. Reported health impacts include greater stress, pain, depression, sleep problems, and irritability, decreased social connectedness and quality of life. Informal family caregivers face negative health outcomes and distress as a result of greater caregiver burden and intensity during the COVID-19 pandemic. Immediate solutions are needed to alleviate this growing burden and provide ongoing support. Future work should explore the potential of boosting positive resources such as resilience and purpose to ease caregiver burden.

THE LIVE LONG WALK STRONG REHABILITATION PROGRAM: WHAT FEATURES IMPROVE MOBILITY SKILLS? VIRTUAL PILOT

Rebekah Harris,¹ Jonathan Bean,¹ Elisa Ogawa,² Addie Middleton,² and Catherine Kelly,² 1. *VA Boston Healthcare System, VA Boston Healthcare System, Massachusetts, United States*, 2. *VA Boston, Boston, Massachusetts, United States*

To evaluate the feasibility of delivering the Live Long Walk Strong (LLWS) rehabilitation program among community dwelling, mobility limited older Veterans in the VA Boston Healthcare System. Community dwelling Veterans 50 years and older identified as being at high risk for mobility decline based on self-report task modification and AM-PAC mobility questions. All Veterans received 10 sessions over 8 weeks of LLWS Physical Therapy care focusing on novel impairments related to mobility decline and behavioral change strategies. Sessions were delivered 1:1 with a Physical Therapist over

45 minutes. To assess feasibility, we tracked recruitment and retention metrics. We assessed length of each session, number of sessions attended, and any reason for withdrawal. To examine technological feasibility, we recorded number and type of issue along with resolution of the issue. A total of 178 Veterans were contacted to participate. Twenty Veterans were enrolled into the LLWS virtual pilot between October 2020 – May 2021. Among our 20 enrolled, 5 did not complete the program. Reasons for not completing included: being enrolled in another exercise study simultaneously and non-related medical complications. Among those completing, an average of 9.7 out of 10 intervention sessions were completed. An average of 1.8 technology difficulties per Veteran was experienced within the intervention. The most frequent technology issues experienced were related to camera positioning and Wi-Fi bandwidth resulting in delayed video and audio. LLWS is feasible to deliver as a virtual mode of care in middle and older aged Veterans at high risk for mobility decline.

THE MEDIATION EFFECTS OF PERCEIVED HEALTHCARE DISCRIMINATION ON RACIAL AND ETHNIC DISPARITIES IN END OF LIFE CARE

Junghee Han, *University of Southern Indiana, Evansville, Indiana, United States*

Numerous studies demonstrate racial and ethnic differences in end-of-life (EOL) care, including place of death and hospice use. Experiencing discrimination in healthcare is often cited in the literature as a potent source explaining the pathways of the racial and ethnic disparities in EOL care. However, none of the studies have tested its mediating effects on racial and ethnic disparities in EOL care. The study examines if the effects of race and ethnicity on place of death and hospice use are mediated by perceived healthcare discrimination. This is a secondary analysis of 2008-2014 data from the nationally representative Health and Retirement Study, including oversampling of Blacks and Hispanics. Samples included 1,446 decedents aged 65 or older who completed an exit interview by proxy. Perceived healthcare discrimination was measured by a self-report of receiving poorer service or treatment than other people from doctors or hospitals. In multivariate analyses, Blacks were more likely to die at hospitals (OR=1.57, $p < .05$) than Whites. Those who experienced discriminatory healthcare were more likely to die at hospitals than those who never experienced discriminatory healthcare (OR=1.44, $p < .05$). However, the Karlson-Hoem-Breen (KHB) method showed no significant mediating effects of perceived healthcare discrimination on racial and ethnic disparities in place of death. Race and ethnicity did not affect hospice use. Although there is no mediating effect of healthcare discrimination on racial and ethnic disparities in EOL care, its direct impact is observed. The research contributes to evidence on the significant role of discrimination in healthcare choices.

THE RELATIONSHIP BETWEEN FAMILY CAREGIVERS' ANTICIPATORY GRIEF AND SEVERITY OF DEMENTIA.

Nicole Gavin,¹ Mu Shan,² Shelly Johns,³ Katherine Judge,⁴ and Nicole Fowler,¹ 1. *Indiana University School of Medicine, IU Center for Aging Research, Indianapolis,*

Indiana, United States, 2. Indiana University, Indianapolis, Indiana, United States, 3. Indiana University School of Medicine, Center for Health Services Research, Indianapolis, Indiana, United States, 4. Cleveland State University, Cleveland, Ohio, United States

Anticipatory grief is the process of experiencing normal bereavement before the physical death of a significant person. To date, anticipatory grief has been related to higher levels of caregiver depression, anxiety, subjective burden, and poorer problem solving. Additionally, higher levels anticipatory grief are observed in caregivers of those with Alzheimer's Disease and Related Dementias (ADRD) compared to caregivers of those with mild cognitive impairment, implying a relationship between disease severity and caregiver anticipatory grief. Analyses were performed on data for ADRD caregivers (n=56) enrolled in the IU Telephone Acceptance and Commitment Therapy for Caregiver (TACTICs) trial; an RCT evaluating an ACT intervention for ADRD caregivers with anxiety. Inclusion criteria included identifying as the primary caregiver of an ADRD patient, and clinically significant anxiety (GAD7 score >10). The average age of caregivers was 61.9 years, 41.1% were spouses, 83.9% were white and 14.3% were black. Mean anticipatory grief scores were notably higher (84.6) compared to the previously reported means across the literature (74.9). Using multiple regression models, we determined a caregivers' anticipatory grief, as measured by the anticipatory grief scale, is not significantly associated with the patients' dementia severity, as measured by the Dementia Severity Rating Scale (DSRS) (p=0.66). Results revealed that higher levels of caregiver burden, as measured by the Zarit Burden Index, are significantly associated with more anticipatory grief (p< 0.01). Understanding these relationships contributes to a better understanding of ADRD caregivers, identifying "high-risk" caregivers, and informing future interventions and care.

UNDERSTANDING FUNCTIONAL MOBILITY AND QUALITY OF LIFE AMONG ISOLATED AGING POPULATION IN THE US

Jessika Dayrit,¹ Ana maria Pasatiempo,² and Kevin Hitosis,³
 1. Washington University in St. Louis, Tamuning, Guam, United States, 2. Department of Veterans Affairs, Department of Veterans Affairs, Alaska, United States, 3. Department of Veterans Affairs, Agana Heights, Guam, United States

Background: Social isolation among older adults linked to serious health conditions. However, little is known if functional mobility among isolated aging adults impacts quality of life. Objectives: This study will examine the association between levels of functional mobilities and risks for developing depression, poor health status, and physical inactivity by controlling socioeconomic factors. Methods: This is a cross-sectional study, using Behavioral Risk Factor Surveillance System (BRFSS) data 2017. Target population are over age 65 who are living alone (N=50,784). Outcome variables are depression, self-reported health status, and physical inactivity whereas main predictors are activities of daily living (ADL) and instrumental activities of daily living (IADL) controlling for gender, race, marital status, employment status, annual income, and educational level. Weight adjustment analysis and logistic regression were conducted.

Results: Depression, self-reported poor health status, and physical inactivity are higher among isolated aging adults who have limitations with ADL/IADL. Specifically, those with difficulties concentrating/decision making (OR=3.62; CI=3.35-3.91) have higher chance of developing depression than those who do not have this limitation. Female are at risk for developing depression (OR=1.41-1.61; CI=1.51), yet they are likely to report for better health status (OR=1.54; CI=1.45-1.64) than males. Asian (OR=0.56; CI=0.39-0.381), Black or African American (OR=0.54; CI=0.48-0.60) are less likely to be diagnosed with depressive disorder than White. Discussion/Recommendation: Physical and cognitive changes that come with aging can pose challenge, as functional capacity diminishes in home environment. Further research should be explored in longitudinal studies on mobility and improving quality of living among isolated aging population.

VIRTUAL TESTING OF SENIORS: THE FEASIBILITY OF RESEARCH WITH ONLINE NEUROPSYCHOLOGICAL TESTS (FRONT)

Chris Pauley,¹ Linda Yetman,² Jody-Lynn Lupo,³ Penelope Slack,⁴ Diane Jacobs,⁵ Chris McGibbon,⁶ Pamela Jarrett,² and Manuel Montero Odasso,⁷
 1. Horizon Health New Brunswick, Saint John, New Brunswick, Canada, 2. Horizon Health Network, Horizon Health Network, New Brunswick, Canada, 3. University of California San Diego, Alzheimer's Disease Cooperative Study (ADCS), UC San Diego, Alzheimer's Disease Cooperative Study (ADCS), California, United States, 4. University of British Columbia, Vancouver, British Columbia, Canada, 5. University of California San Diego, La Jolla, California, United States, 6. University of New Brunswick, Fredericton, New Brunswick, Canada, 7. Lawson Research Institute, London, Ontario, Canada

Synergic@Home is a feasibility study evaluating the effects of exercise and cognitive interventions for the prevention of dementia in at-risk individuals over age 60. The COVID-19 pandemic changed the study's methods, with standardized neuropsychological tests needing to be administered virtually. Experience and research into the viability of neuropsychological assessments administered virtually is limited. After receiving permission to adapt the tests for virtual administration, a neuropsychologist, project managers, and research coordinators developed their approach. A PowerPoint presentation using text and visual stimuli from the tests was developed with on-screen instructions for the raters. An iterative development process involved feedback from the team in order to maximize the fidelity of these methods compared to in-person administration. Mock assessments supervised by a neuropsychologist further refined the methods and confirmed rater adherence to standardized procedures. A secure videoconferencing platform meeting privacy requirements was used. Dual monitors for the raters provided instructions on one monitor while stimuli for the participant was on the second monitor. The participant could only see the stimuli. This method of administering neuropsychological assessment, the Feasibility of Research with Online Neuropsychological Testing (FRONT), is being used to evaluate older adult participants in Synergic@Home. Results from this feasibility study may set the stage for new research methodologies and/or clinical evaluations

in the future. This project is funded by the New Brunswick Healthy Seniors Pilot Project and the Canadian Consortium on Neurodegeneration in Aging (with grants from Public Health Agency of Canada and the Canadian Institutes of Health Research, with additional funding partners).

WHAT WORKS AND WHAT DOESN'T: GERONTOLOGY FOCUSED PHD/ DSW GRADUATES SPEAK OUT

Matthew Myrick,¹ and Lauren Snedeker,² 1. *Widener University, PHILADELPHIA, Pennsylvania, United States,*
2. *Rutgers University, New Brunswick, New Jersey, United States*

Lin et al. (2015) projected there would be a shortage of approximately 195,000 social workers in the United States by 2030. In the next twenty years, it is estimated that Americans over the age of 65 will actually outnumber children under the age of 18 (US Census, 2018). With a longstanding reputation for being less “glamorous”, social work with older adults will continue to experience deficits in the amount of those who commit to this field of practice unless more lasting change occurs (Cummings et al., p. 645, 2005). We must take a closer look at what takes place in the classroom at schools of social work to understand why social workers are not interested in working with older adults (Scharlach et al., 2000). Berkman et al. (2016) described in their work that a critical shortage of gerontology-focused social work faculty exists in schools of social work. Thus, we cannot expect more social workers to work with older adults unless they are exposed to this work in their educational programs. The purpose of this study is to report on the academic experience, research agenda, professional experiences (practice and teaching), and future goals of social work PhD/ DSW graduates. Ten social work doctoral graduates were interviewed in order to understand the impact their academic programs had on their commitment to older adults in their field and to learn their recommendations for schools of social work in an effort to sustain and grow the gerontological workforce.

Session 9505 (Late Breaking Poster)

Late Breaking Poster Session II

A PLATFORM TO STUDY THE EFFECTS OF HOME ENVIRONMENT ON HEALTH AND WELLBEING OF OLDER ADULTS

Amir Baniassadi,¹ Brad Manor,² Wanting Yu,³ Lewis Lipsitz,³ and Alvaro Pascual-Leone,⁴ 1. *Harvard Medical School, Hinda and Arthur Marcus Institute for Aging Research, Boston, Massachusetts, United States,*
2. *Hinda and Arthur Marcus Institute for Aging Research, Harvard Medical School, Boston, Massachusetts, United States,*
3. *Hebrew SeniorLife, Boston, Massachusetts, United States,*
4. *Harvard Medical School, Boston, Massachusetts, United States*

While older adults' living environment is rarely well-tuned to their specific needs, technological advances provide new opportunities to understand, and ultimately optimize, the relationship between the home environment and health outcomes. We aimed to establish proof-of-concept and

feasibility of a platform enabling real-time, high-frequency, and simultaneous monitoring of environment, biological variables, and outcomes related to health and wellbeing in older adults. We recruited 7 participants (6 females, 1 male, aged 78-90, MoCA scores 14–28), installed environmental sensors measuring temperature, humidity, and CO2 inside their homes, provided them with wearables that measure sleep, activity, body temperature, and heart rhythms, and asked them to use a tablet to complete four sets of questionnaires and cognitive tests per day for three consecutive weeks. Environmental sensors collected data with no disruption or complaint from participants. Average compliance with the wearables was 81% (ring) and 60% (watch). All participants preferred the ring due to ease-of-use. Compliance was better in those with higher MoCA scores. Three participants were able to use the tablet successfully and completed 90% of prescribed questionnaires and cognitive tests. Cognitive and/or motor issues prevented the other participants from using the tablet. Exit interviews revealed that participants would prefer to complete a maximum of two sets of daily questionnaires and cognitive tests (five minutes each) in longer-term studies. These results suggest that it is feasible to study the impact of the environment on biological rhythms, cognition, and other outcomes in older adults and provide recommendations for ensuring long-term compliance with the protocol.

A SCOPING REVIEW OF PSYCHOLOGICAL SENSE OF COMMUNITY AMONG COMMUNITY DWELLING OLDER ADULTS

Thomas Buckley, *University of Pittsburgh, Virginia Beach, Virginia, United States*

Psychological sense of community (PSOC) is an important construct for health and well-being outcomes for older adults. Drawing on the Ecological Theory of Aging and the Age-Friendly Cities (AFC) framework, this scoping review explored how PSOC has been used in research with community dwelling older adults. I followed Arksey and O'Malley's (2005) scoping review guidelines. Initial database searches yielded 860 articles. I included 33 in the final sample. I grouped articles based on study populations and conceptualization and operationalization of PSOC. I used thematic analysis to explore topic areas and main findings. The AFC framework guided development of themes and others emerged during analysis. Results show most studies used Asian or White samples and focused on geographic community or neighborhoods. Among the several measures of PSOC, the Brief Sense of Community Scale performed best with older adults. Topical research areas in the thematic analysis were built (1) built environment and neighborhoods, (2) social participation and connection, (3) civic participation, (4) PSOC as a protective factor, (5) health and well-being, (6) relocation, and (7) scale development. PSOC was a consistent predictor of health and well-being and served as a mediator to link neighborhood or environmental characteristics with health and well-being. Future research needs to examine PSOC in geographically and culturally diverse samples and conduct further psychometric testing of PSOC scales with older adults. PSOC is conceptually related to the AFC framework and serves as a mechanism that links AFC features and well-being outcomes. These results can inform practice and refine theory.

A STUDENT-LED COMMUNITY OUTREACH TELEHEALTH PROGRAM FOR COVID EDUCATION AND HEALTH PROMOTION (COACH)

Michelle Yang,¹ Cam Clayton,² Devin Harris,³ Chelsea Pelletier,⁴ Julia Schmidt,² Jill Zwicker,² and Brodie Sakakibara,⁵ 1. *University of British Columbia, Richmond, British Columbia, Canada*, 2. *University of British Columbia, Vancouver, British Columbia, Canada*, 3. *Interior Health Authority, Kelowna, British Columbia, Canada*, 4. *University of Northern British Columbia, Prince George, British Columbia, Canada*, 5. *University of British Columbia, Kelowna, British Columbia, Canada*

While public health measures of quarantining, socially isolating, and physical distancing are important to minimize the spread of coronavirus (COVID-19), these actions may also compromise the ability to manage one's own health, thereby increasing the risk of adverse health events. The purpose of this study was to evaluate a student-delivered Community Outreach telehealth program for Covid education and Health promotion (COACH) to community-living adults (age ≥ 65 years). We hypothesized that COACH would improve health promoting behaviour as measured by the Health Directed Behaviour subscale of the Health Education Impact Questionnaire. We also anticipated COACH would improve secondary outcomes of perceived stress, depressive and anxiety (Depression, Anxiety, and Stress Scale-21), social support (Medical Outcomes Study Social Support Survey), health-related quality of life (Short Form-36), and health promotion self-efficacy (Self-Rated Abilities for Health Practices Scale). In this single-group pre-post study, we recruited 75 community-living adults with access to telephone/video-conferencing technology to participate in six 30-45 minute sessions with trained medical students over a two-month period. The mean age of participants was 72.4 years (58.7% female), with 80% reporting two or more chronic conditions. No participants were diagnosed with COVID-19 during participation. Paired sample t-tests showed significant improvement in health directed behaviour ($p < .001$, $d = 0.45$) and self-efficacy ($p < .001$, $d = 0.44$), but significant decrease in mental health-related quality of life ($p < .001$, $d = -1.69$). Overall, COACH may help improve health directed behaviour and health promotion self-efficacy, despite decreases in mental health possibly associated with COVID-19 restrictions.

A VIRTUAL COMPANIONSHIP INTERVENTION REDUCES LONELINESS DURING THE COVID-19 PANDEMIC

Ellen Rudy, Kelsey McNamara, Rajiv Patel, and Corey Sturm, *Papa Inc., Miami, Florida, United States*

Loneliness and social isolation are established risk factors for many clinical conditions yet few scalable interventions exist. Papa Inc. is a national service that pairs older adults with "Papa Pals" (empathetic, laypeople) who provide companionship and assistance with everyday tasks. Participants have free access if their Medicare Advantage plan offers it. During the COVID-19 pandemic, Papa provided virtual companionship visits via telephone or video. This study evaluated the impact of virtual companionship visits on loneliness status (UCLA 3-item Loneliness Scale) during the COVID-19 pandemic. The sample (N=894) included adults

ages 65+ who identified as lonely at baseline and who completed at least one virtual visit between March 18, 2020 and December 31, 2020. Virtual visits were classified into four categories based on participants' total number of visit minutes: Low (124 ave min), Medium Low (ML) (305 ave min), Medium High (MH) (567 ave min), and High (1360 ave min). Lonely and severely lonely participants engaged a mean of 573 and 673 minutes in the program, respectively. Improvement in loneliness status was associated with greater use of minutes for the ML and MH participants compared to Low participants (ML OR: 1.46 95CI: 1.00 - 2.11, MH OR 1.65 95CI: 1.13 - 2.40). These findings indicate that a virtual companionship intervention can be an impactful and scalable tool for older adults who want to age at home and have limited social support, especially during the uncertain COVID landscape. Further research is warranted to understand persistent loneliness.

ACETYLATION OF TAU INDUCES ALZHEIMER'S DISEASE-ASSOCIATED TAU IN TRANSGENIC MICE

Addison Ali,¹ Kristeen Pareja,² and Tara Tracy,³ 1. *University of California, Davis, Martinez, California, United States*, 2. *Buck Institute, Buck Institute, California, United States*, 3. *Buck Institute for Research on Aging, Novato, California, United States*

Alzheimer's disease (AD) is a neurodegenerative disorder that is characterized by neurofibrillary tangles (NFTs) and amyloid beta plaques. These NFTs are made up of aggregated tau proteins. Tau is involved in stabilizing microtubules and does not usually display aggregation. Acetylation of tau protein causes an increase in tau aggregation but its role in AD progression is still not well understood. I hypothesized that enhanced acetylated tau results in an increase in AD-like tau pathology. To test this, a murine prion promoter-tauKQ transgene was injected into the mouse fertilized oocyte. The tauKQ mutation alters lysine to glutamine to mimic acetylation of tau. Nontransgenic mice were used as controls. AT8 and GT-38 antibodies were used in immunohistochemistry (IHC) to target phosphorylated tau and AD-associated tau, respectively. GT-38 is conformation-dependent and requires 3R and 4R tau isoforms which makes it specific to AD. Through immunofluorescence, increased phosphorylated tau was observed in the hippocampus of the tauKQ mice compared to the nontransgenic mice. I focused on the dentate gyrus, CA1 region, and the mossy fibers of the CA3 region since they are involved in many memory processes. Through chromogenic IHC, the tauKQ mice exhibited more 3R+4R tau isoform pathology in the mossy fibers than the nontransgenic mice. This data suggests that an acetylation mimic is sufficient to stimulate an abundance of AD-related tau pathology in transgenic mice which is consistent with my hypothesis. The tauKQ mouse model can assist in understanding the role of tau acetylation and tau progression for AD.

ADULT DAY SERVICE USE AMONG ETHNIC MINORITY OLDER ADULTS: AN UPDATED INTEGRATIVE REVIEW

Yawen Li,¹ Ling Xu,² Jinyu Liu,³ and Fei Sun,⁴ 1. *California State University San Bernardino, San Bernardino, California, United States*, 2. *University of Texas at Arlington, Arlington, Texas, United States*, 3. *Columbia University, Columbia*

University, New York, United States, 4. Michigan State University, East Lansing, Michigan, United States

Adult day services (ADS) are a preferred care option for racial and ethnic minorities compared to other types of long-term care services in the United States. However, there is limited knowledge on minority ADS users. Focusing on minority older adults, this study aims to (a) identify facilitator and barriers of ADS use, and (b) examine ADS's effect on health and wellbeing. Using Whittemore and Knaf's methodology of integrative reviews, we searched relevant studies published between 2010 to 2020 in Ageline, PubMed, PsycINFO, CINAHL, Web of Science and Google Scholar and included 8 articles in this review after extensive screening and critical appraisal. Crowe Critical Appraisal Tool (CCAT) was used to assess methodological rigor of the studies included in this review. This review showed that individual factors of ADS use among minority older adult included functional impairment, diabetes, race, gender, and degree of loneliness. Organizational characteristics, such as availability of transportation services, bilingual nurses, peer support, and cultural activities, and structural factors including for-profit status and source of payment were also related to ADS use among minority older adults. Positive outcomes associated with ADS use were improved quality of life and sense of fulfillment. Better understanding of minority older adults' experience with ADS will help tailor the services to better fit their cultural preferences and needs. Future research should move beyond individual-level factors to identify and address organizational and structural factors such as institutional structure, organization culture and practice impact on disparities and discrimination in services access and quality.

ADVERSE CHILDHOOD EXPERIENCES ASSOCIATED WITH EPIGENETIC AGE AND DEPRESSIVE SYMPTOMS IN OLDER ADULTS

Eric Klopak,¹ Judith Carroll,² Eileen Crimmins,¹ Steve Cole,² and Teresa Seeman,² 1. *University of Southern California, Los Angeles, California, United States*, 2. *University of California, Los Angeles, Los Angeles, California, United States*

Adverse childhood experiences (ACEs) increase risk for depression in adolescents and older adults and have been linked to accelerated biological aging. We hypothesized that accelerated epigenetic aging may partially explain the link between ACEs and depression. This study examines second-generation epigenetic clocks (viz., GrimAge, PhenoAge, and DunedinPoAm38) as mediators of the link between ACEs and depressive symptoms in older adulthood. We utilize structural equation modeling to assess mediation in the Innovative Subsample of the Venous Blood Study from the Health and Retirement Study (N = 2672). Results indicate that experiencing more than 1 ACE is significantly associated with greater GrimAge and DunedinPoAm38, with limited evidence of increasing aging with increasing ACEs. GrimAge and DunedinPoAm38 were also significantly associated with more depressive symptoms. These associations were partially reduced by lifestyle factors. GrimAge explained between 9 and 13% of the association between ACEs and adult depressive symptoms, and DunedinPoAm38 explained between 2 and 7% of the association between ACEs and adult depressive symptoms. Findings indicate that accelerated aging,

as measured by GrimAge and DunedinPoAm38, is strongly associated with ACEs in older Americans, that these clocks are highly associated with depressive symptoms in older Americans, and that these clocks mediate a proportion of the association between ACEs and adult depressive symptoms. Epigenetic clocks may represent a physiological mechanism underlying the link between early life adversity and adult depression. Lifestyle factors are a potential area for intervention.

AGE-RELATED CHANGES IN ONGOING THOUGHT RELATE TO EXTERNAL CONTEXT AND INDIVIDUAL COGNITION

Adam Turnbull,¹ Giulia Poerio,² Feng Lin,³ and Jonathan Smallwood,⁴ 1. *University of Rochester Medical School, Rochester, New York, United States*, 2. *University of Essex, Colchester, England, United Kingdom*, 3. *Stanford, Stanford, California, United States*, 4. *Queen's University, Kingston, Ontario, Canada*

Understanding how age-related changes in cognition manifest in the real world is an important goal for aging research. One means of capturing these changes involves "experience sampling" participant's self-reported thoughts as they go about their daily lives. Previous research using this method has shown age-related changes in ongoing thought: e.g., older adults have fewer thoughts unrelated to the here-and-now. However, it is currently unclear how these changes reflect cognitive aging or lifestyle changes. 78 younger adults and 35 older adults rated their thought contents along 20 dimensions and the difficulty of their current activity in their daily lives. They also performed cognitive tasks in the laboratory. In a set of exploratory analyses using Principal Component Analysis (PCA), we found that older adults spent more time thinking positive, wanted thoughts, particularly in demanding contexts, suggesting they may use different strategies to regulate their emotions. In line with previous research, older adults spent less time mind wandering about their future selves. Past-related thought related to episodic memory differently in older and younger adults. Additionally, PCA analyses performed separately in older and younger adults showed high similarity to an analysis performed on the combined sample, suggesting a similar structure to ongoing daily life thought in older and younger adults. These findings inform the use of experience sampling to understand cognitive aging, highlighting the need to consider content along multiple dimensions as well as the context in which thoughts are reported when analyzing aging ongoing thought.

AGE-RELATED CHANGES IN POSTURE STEADINESS IN THE COMPANION DOG

Alejandra Mondino Vero,¹ Grant Wagner,¹ Edgar Lobaton,¹ Katharine Russell,² and Natasha Olby,³ 1. *North Carolina State University, Raleigh, North Carolina, United States*, 2. *NCSU, NCSU, North Carolina, United States*, 3. *North Carolina State University, NCSU, North Carolina, United States*

Aging is associated with changes in the sensory-motor system that could lead to dynamic instability. In fact, postural control deficits have been proposed as an early indicator of frailty. Measurements of the displacement of the center of pressure (COP) using pressure mat data are useful tools to determine postural steadiness. Companion dogs represent a

powerful model to study aging in people because they share our environment and experience similar age-related diseases. To date, the effect of aging on postural control in dogs has not yet been evaluated. The aim of this study was to determine the correlation between age and the displacement of the COP in dogs during quiet standing. Due to the diversity of life expectancy in dogs according to their body size, age was normalized as a fraction of the predicted life expectancy. Dogs older than 75% of their life expectancy (n=18) were asked to stand on a pressure mat for 8 seconds per trial during at least five trials. Only the frames where the dogs were standing still and facing forward were analyzed. Age as a fraction of life expectancy was significantly correlated ($p < 0.05$) with the Medio-lateral Range, Root-Mean-Square Distance, 95% Confidence Ellipse, and Total Sway Area of the COP. These results show that, as in humans, aging in dogs is associated with postural control deficits and therefore reinforce the dog as a suitable model for translational studies of aging and postural steadiness.

AGING SERVICES WORKERS IN THE PANDEMIC: VOICED EXPERIENCE OF SENIOR CENTER STAFF & CASE WORKERS

Esther Okang,¹ Siobhan Aaron,² Katherine Supiano,² and Abdul Osman,² 1. *University of Utah, Salt Lake City, Utah, United States*, 2. *University of Utah, Salt Lake City, Utah, United States*

The pandemic necessitated immediate shutdown of senior centers, requiring a rapid pivot in the delivery of services to older adults by direct care workers. We provided psychosocial support to older adult service personnel-including Aging and Adult Services case workers and Senior Center Staff, and conducted focus groups with staff at intervals to capture the mid-point of the pandemic (peak of older adult deaths), onset of vaccine availability and the re-entry phase as programs re-opened. We evaluated coping and self-efficacy of workers and discerned sustained high levels of coping and perceived job performance. Using a phenomenological lens, we analyzed transcribed recordings, generated codes, and created categories of experiences. Several themes emerged: personal and professional resilience, passion for serving older adults, motivation to perform their job well, stress of not having face-to-face contact with clients, insufficient resources-especially in rural areas, lack of essential training, feeling disjointed as a team, and work-life balance. Over the course of the pandemic, workers expressed increasing resiliency and skills to navigate the pandemic, oscillations in their fears for their clients' well-being, and gratitude that they kept their jobs and gained additional State resources. As the vaccine was available and utilized, and as senior centers were reopening, senior center staff were enthusiastic, yet case workers remained apprehensive about long-term consequences of the pandemic. This study affirms the role of direct care workers as essential and valuable. Yet, their expressed need for more education, psychosocial support, and community awareness of their service remains to be addressed.

AN ONLINE COMMUNITY INTERVENTION FOR OLDER PERSONS WITH PRE-FRILTY AND FRILTY: PILOT STUDIES

Oleg Zaslavsky,¹ Frances Chu,² Shaoqing Ge,³ Andrew Teng,² Shih-Yin Lin,⁴ George Demiris,⁵ and

Annie Chen,² 1. *University of Washington, Seattle, Washington, United States*, 2. *University of Washington, University of Washington, Washington, United States*, 3. *University of Washington School of Nursing, Seattle, Washington, United States*, 4. *New York University, New York, New York, United States*, 5. *School of Nursing, University of Pennsylvania, University of Pennsylvania, Pennsylvania, United States*

Online community interventions can support self-management in older populations but have rarely targeted symptomology of pre-frailty and frailty. To support older adults' pre-frailty/frailty symptom management, we iteratively refined an approach entitled Virtual Online Community for Aging Life Experience (VOCALE) in three consecutive pilot studies (2018-2020). These studies employed asynchronous online discussions in which participants were asked to respond to weekly prompts. A study facilitator moderated the discussion, encouraging participants to respond to both the prompts and comments of other participants. In the first pilot (n=8), participants engaged in a collective exploration of different symptoms of pre-frailty and frailty. The second (n=10) and third (n=10) pilots employed a hybrid approach including collaborative exploration and learning of different problem-solving therapy skills over eight weeks. The mean age of participants of the three pilots combined was 80.6 (SD = 7.0). Most participants were female (71%). Participant attrition ranged from 20-25%. Many participants who completed the study noted that they enjoyed the discussions. The participants also found the moderators' follow-up questions and support timely and engaging. Additionally, we observed small but positive changes in self-efficacy measures. These pilot studies have confirmed that older adults with pre-frailty and frailty are interested, and can successfully engage in online community interventions, with the technical support and moderation provided, even during the initial stages of the COVID-19 pandemic, when lockdown policies were rolled out. Participation in the intervention was also associated with increased awareness of the need to be proactive in self-management concerning frailty-related symptoms.

ASSESSING CARDIOMETABOLIC HEALTH RISK IN CHILDREN LIVING WITH GRANDPARENT PRIMARY CAREGIVERS: INTERIM ANALYSIS

MinKyoung Song,¹ Laura Hayman,² Karen Lyons,³ Hannah Bessette,¹ Mary Roberts Davis,¹ Kerri Winters-Stone,¹ and Carol Musil,⁴ 1. *Oregon Health & Science University, Portland, Oregon, United States*, 2. *University of Massachusetts Boston, Boston, Massachusetts, United States*, 3. *Boston College, Chestnut Hill, Massachusetts, United States*, 4. *Case Western Reserve University, Cleveland, Ohio, United States*

Minimal research has been conducted on the effect that grandparents as primary caregivers have on the cardiometabolic health of children who live with them, even though a number of studies have examined the influence of parent caregivers. As a first step towards filling that gap, we examined physiological and behavioral indicators of cardiometabolic health risk among children (aged 7 to 12 years) living with grandparent primary caregivers in Oregon and Washington. We measured body mass index and total cholesterol/glycohemoglobin (HbA1c), as well as

physical activity/sleep and diet. In this preliminary analysis of our findings with 10 dyads (mean age 64.2 ± 4.0 years for grandparents; 9.3 ± 1.9 years for grandchildren), we report that on most of the indicators - obesity, physical activity, sleep, and diet - these children's levels were comparable to national averages across all household types (not differentiated by type of family structure). However, 25% of the grandchildren ($n=2$) participating in our study had a total cholesterol level ≥ 200 , compared to 7.4% of children from a nationally representative dataset. Similarly, 14% of the grandchildren ($n=1$) participating in our study had HbA1c $\geq 6.5\%$, compared to $< 0.5\%$ of children from a nationally representative dataset. Our findings suggest that these children may be at higher cardiometabolic health risk (e.g., hyperlipidemia). Further investigations with a larger sample and more examination of cardiometabolic risk profiles including lipids/blood glucose assessment are required to validate our preliminary findings.

ASSOCIATION OF DUAL SENSORY IMPAIRMENT WITH INCIDENT MOBILITY AND ADL DIFFICULTY

Nicole Armstrong,¹ Camila Vieira Ligo Teixeira,² Willa Brenowitz,³ Bonnielin Swenor,⁴ Eleanor Simonsick,⁵ Richard Jones,⁶ and Colby Gendron,⁷ 1. Warren Alpert Medical School of Brown University, Providence, Rhode Island, United States, 2. NIA/NIH Biomedical Research Center, Baltimore, Maryland, United States, 3. UCSF, UCSF, California, United States, 4. Johns Hopkins University, Baltimore, Maryland, United States, 5. National Institute on Aging, National Institute on Aging, Maryland, United States, 6. Brown University, Providence, Rhode Island, United States, 7. Brown University, Brown University, Rhode Island, United States

Hearing and vision impairment are each independently associated with incident mobility disability and disability in activities of daily living (ADL). Whether dual sensory impairment (DSI) in both hearing (pure-tone average >25 dB) and vision (impaired visual acuity and/or impaired contrast sensitivity) is associated with greater risk of incident mobility and ADL difficulty, as compared to single or no sensory impairments, has not been well-studied. To examine these associations, we used data from 2,020 Health Aging and Body Composition Study participants aged 70-79 years without mobility limitations. Incident mobility difficulty was defined as the first instance of a lot of problems or inability to walk $\frac{1}{4}$ mile and/or climb 10 steps, and incident ADL difficulty was defined as the first instance of problems with any ADL. Cox proportional hazards models adjusted by demographic covariates, diabetes, hypertension, and depressive symptoms were used to model these associations. Approximately 22.7% of the study had DSI. DSI was associated with increased risk of both incident mobility (Hazard Ratio [HR]=2.43, 95% Confidence Interval [CI]: 1.60, 3.69) and ADL difficulty (HR=2.39, 95% CI: 1.60, 3.56). Vision impairment only was associated with risk of incident mobility difficulty (HR=1.74, 95% CI: 1.09, 2.78), but not incident ADL difficulty (HR=1.45, 95% CI: 0.91, 2.32). Hearing impairment only was not associated with risk of either outcome. Synergistic effects of DSI on the additive scale were present. Sex and race did not modify associations. Monitoring of DSI may be beneficial in delaying incident difficulty.

ASSOCIATION OF DUAL SENSORY IMPAIRMENT WITH LONG-TERM DEPRESSIVE AND ANXIETY SYMPTOMS

Nicole Armstrong,¹ Camila Vieira Ligo Teixeira,² Willa Brenowitz,³ Bonnielin Swenor,⁴ Danielle Powell,⁴ Eleanor Simonsick,⁵ Richard Jones,⁶ and Colby Gendron,⁷ 1. Warren Alpert Medical School of Brown University, Providence, Rhode Island, United States, 2. NIA/NIH Biomedical Research Center, Baltimore, Maryland, United States, 3. UCSF, UCSF, California, United States, 4. Johns Hopkins University, Baltimore, Maryland, United States, 5. National Institute on Aging, National Institute on Aging, Maryland, United States, 6. Brown University, Providence, Rhode Island, United States, 7. Brown University, Brown University, Rhode Island, United States

Hearing (HI) and vision impairment (VI) are each independently associated with long-term depressive and anxiety symptoms, but the joint effects of both (DSI) may be associated with a greater risk of belonging to long-term chronically high depressive and anxiety trajectory classes. Multinomial logistic regression models adjusted by demographics and depressive symptoms were used to examine the associations of dual hearing (pure-tone average >25 dB) and vision impairment (impaired visual acuity and/or contrast sensitivity) with long-term depressive and anxiety symptom trajectory classes among 2,102 participants of the Health, Aging and Body Composition Study, a cohort of older adults without mobility difficulty aged 70-79 years. An additional model evaluated the two-way interaction between DSI and social contact. Elevated depressive symptoms were defined as ≥ 8 on the 10-item Center for Epidemiologic Studies-Depression Scale, and anxiety symptoms were defined as present on the Hopkins Symptom Checklist. DSI was associated with increased risk of being chronically depressed (Risk Ratio, RR=1.86, 95% Confidence Interval, CI: 1.19, 2.92), not periodically depressed (RR=1.24, 95% CI: 0.91, 1.69). Those with DSI were at an increased risk of belonging to the periodically anxious (RR=1.56, 95% CI: 1.14, 2.13) and chronically anxious (RR=1.79, 95% CI: 1.02, 3.12) groups, as compared to the other groups. Single sensory impairments were not associated with increased risk of being periodically or chronically anxious. Social contact did not modify any associations. Synergistic effects between HI and VI were present. Those with DSI may be at greater risk for mood disorders, so sensory evaluations may mitigate these.

ASSOCIATION OF SEDENTARY AND ACTIVE BOUT FREQUENCY WITH MORTALITY IN OLDER MEN USING ACCELEROMETRY

Lauren S. Roe,¹ Stephanie Harrison,² Peggy Cawthon,² Kyle Moored,¹ Kristine Ensrud,³ Katie Stone,⁴ Kelley Pettee Gabriel,⁵ and Jane Cauley,¹ 1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. California Pacific Medical Center, Research Institute, San Francisco, California, United States, 3. University of Minnesota, Minneapolis, Minnesota, United States, 4. University of California, Berkeley, San Francisco, California, United States, 5. The University of Alabama at Birmingham, Birmingham, Alabama, United States

BACKGROUND: Time spent sedentary increases with age and has several negative health consequences. We sought

to examine associations between daily sedentary and active bout frequency with all-cause mortality. **METHODS:** Data are from 2,918 men in the Osteoporotic Fractures in Men (MrOS) study (mean age at Visit 3±SD: 79.0±5.1 years) with valid activity monitor data (5.1±0.3 days worn>90%) at Year 7 visit (Visit 3, 2007-2009). Sedentary and active bout frequencies are defined as the daily transition frequency from a sedentary bout lasting 5+ minutes to activity of any intensity, and the transition frequency from an active bout lasting 5+ minutes to sedentary. Deaths were centrally adjudicated using death certificates. Cox proportional hazard models were used to examine associations between quartiles of sedentary (Q1 referent, <13.6 bouts/day) or active (Q1 referent, <5 bouts/day) bout frequency and mortality. Models were repeated, stratifying by median daily total time spent sedentary and active. **RESULTS:** After 9.4±3.7 years of follow-up, 1,487 (51.0%) men died. Men averaged 16.9±5.1 and 8.2±4.2 sedentary and active bouts/day, respectively. After full covariate adjustment, each quartile reflecting a higher sedentary (Q4 vs Q1 HR: 0.68, 95%CI: 0.58-0.81, p-trend<0.001) and active bout (Q4 vs Q1 HR: 0.57, 95%CI: 0.48-0.68, p-trend<0.001) frequency was associated with lower mortality risk. There was no evidence that effects differed by total sedentary time (p-interaction for sedentary bout frequency and total sedentary time>0.05). **CONCLUSIONS:** More frequent, prolonged sedentary and active bouts are associated with a lower mortality risk in older men and is not moderated by total sedentary time.

ASSOCIATIONS BETWEEN HIV STIGMA AND MENTAL HEALTH AMONG OLDER HISPANICS AND WHITES LIVING WITH HIV

Kayle Karcher,¹ Lily Kamalyan,² Veronica Gonzalez,³ Lilla Brody,⁴ Robert Heaton,⁵ Raeanne Moore,⁶ Dilip Jeste,⁷ and Maria Marquine,⁷ 1. *University of California-San Diego, San Bernardino, California, United States*, 2. *San Diego State University/University of California San Diego Joint Doctoral Program in Clinical Psychology, San Diego, California, United States*, 3. *UCSD, San Diego, California, United States*, 4. *Weill Cornell Medicine, New York, New York, United States*, 5. *University of California San Diego, San Diego, California, United States*, 6. *UC San Diego, San Diego, California, United States*, 7. *University of California San Diego, La Jolla, California, United States*

Hispanics/Latinos/as/x (henceforth Hispanics) have higher rates of HIV infection than non-Hispanic (NH) Whites, particularly in older age. People living with HIV (PWH) are at increased risk of stigma and poor mental health, but these associations have not been thoroughly examined in older PWH. We investigated ethnic differences in HIV stigma and its association with mental health in older Hispanic and NH White PWH. Participants included 116 PWH ages 50-75 (58 Hispanic and 58 NH White) from southern California (for the overall cohort: 82.7% male; 57.7% AIDS, 93.9% on antiretroviral therapy). Participants completed self-report measures of HIV-stigma, depression (Beck Depression Inventory-II; BDI-II), and cumulative alcohol use (i.e., lifetime total quantity/total days). Covariates examined included sociodemographic and HIV-disease characteristics. An independent sample t-test showed no significant ethnic differences in HIV stigma (p=.82). Separate multivariable linear regression models on mental health outcomes (adjusting for

significant covariates) showed no significant interaction between HIV stigma and ethnicity on BDI-II scores (p=.83) or cumulative alcohol use (p=.51). Follow up models removing the interaction term, showed that increased HIV stigma was associated with higher BDI-II scores (B=0.34, 95% CI=0.21-0.48; p<.001), but not with cumulative alcohol use (p=.49) in the overall sample. Findings indicate a significant link between HIV stigma and depression symptoms in older PWH, with comparable associations among Hispanics and NH Whites. Future studies examining factors that may moderate the link between HIV stigma and depression in diverse older PWH would help guide the development of interventions aimed at improving mental health in this population.

BIOPSYCHOSOCIAL CORRELATES OF COGNITIVE FUNCTION AMONG KOREAN OLDER ADULTS: HISTORY OF HYPERTENSION AND DIABETES

Kyuyoung Cho,¹ and Hye Won Chai,² 1. *Dong-A University, Busan, Pusan-jikhalsi, Republic of Korea*, 2. *The University of Texas at Austin, Austin, Texas, United States*

Based on biopsychosocial perspectives on health, this study examined risk and protective factors of cognitive function among Korean older adults. Specifically, we focused on comparing the role of these factors based on the respondents' history of having hypertension or diabetes. This study used 2009 Korean National Health Insurance Service data that included a sample of older adults who maintained qualification for health insurance and medical aid in 2002 (n=26,242). Cognitive function was measured using KDSQ-C and biopsychosocial factors included metabolic syndrome, drinking, smoking, and walking. The sample was divided into two groups based on their medical history, and thus four sets of linear regression models were analyzed to explore the associations between biopsychosocial factors and cognitive functioning. Among individuals with a history of hypertension, metabolic syndrome, drinking, and walking were associated with cognitive functioning. For those without a history of hypertension, only drinking and walking were associated with cognitive functioning. For diabetes, smoking and walking were associated with cognitive functioning among older adults with a history of diabetes. For those without a history of diabetes, drinking and walking were associated with cognitive functioning. In sum, metabolic syndrome was a particularly significant correlate of cognitive function among Korean older adults with a history of hypertension. Walking was a consistently significant factor regardless of medical history. These results highlight the importance of considering medical history of chronic conditions such as hypertension and diabetes in identifying factors associated with older adults' cognitive function and further developing tailored prevention programs for cognitive decline.

CAN A DATA-DRIVEN MEASURE OF NEUROANATOMIC DEMENTIA RISK BE CONSIDERED A MEASURE OF BRAIN AGING?

Ramon Casanova,¹ Andrea Anderson,² Jamie Justice,² Gwen Windham,³ Rebecca Gottesman,⁴ Thomas Mosley,⁵ Lynne Wagenknecht,⁶ and Stephen Kritchevsky,² 1. *Wake Forest School of Medicine, Winston-Salem, North Carolina, United States*, 2. *Wake Forest School of Medicine, Wake Forest School of Medicine, North Carolina, United States*, 3. *University of Mississippi Medical Center, Jackson,*

Mississippi, United States, 4. NIH, Bethesda, Maryland, United States, 5. The University of Mississippi Medical Center, Jackson, Mississippi, United States, 6. Wake Forest School of Medicine, Winston Salem, North Carolina, United States

There is an increasing interest in identifying aging-related factors which may be permissive of Alzheimer's Disease (AD) emergence. We previously used machine learning to derive an index of neuroanatomic risk of dementia called AD pattern similarity (AD-PS) score using MRIs obtained in the Atherosclerosis Risk in Communities (ARIC) study. Here, we investigate the potential of the AD-PS scores as a brain-focused measure of biologic age. Among 1970 ARIC participants with MRI collected at ARIC Visit 5, we related AD-PS scores to three measures of aging: mortality (n=356) over 8 years of follow-up; an a priori panel of 32 proteins related to aging (N=1647); and a deficit accumulation index (DAI) based on 38 health-related measures. We found lower AD-PS scores associated with significantly lower mortality (HR=0.58, CI-95%, [0.45 - 0.75], $p < 0.001$) after adjusting for age, race, smoking and hypertension. Among the 32 proteins, nine were significantly associated to AD-PS scores ($p < 0.05$) with 4 remaining significant adjusting for multiple comparisons (Growth/differentiation factor 15, Tumor necrosis factor receptor superfamily member 1A and 1B and Collagen alpha-1(XVIII) chain). Finally, in a linear regression model after adjusting for age, race, sex, hypertension and smoking, AD-PS scores were associated with the DAI ($p < 0.001$). The consistent patterns of associations suggest that a data-driven measure of AD neuroanatomic risk may be capturing aspects of biologic age in older adults.

CARE RECIPIENT DIAGNOSIS MODERATES THE RELATIONSHIP BETWEEN CAREGIVER WORRY AND VIGILANCE

Katherine Craig,¹ Shirrit Kamil-Rosenberg,¹ and J. Kaci Fairchild,² 1. *Veterans Affairs Palo Alto Health Care System, Palo Alto, California, United States*, 2. *VA Palo Alto Health Care System, Palo Alto, California, United States*

Family members of persons diagnosed with dementia or a traumatic brain injury (TBI) are often relied upon to provide daily support to their care recipients. However, research on the differing experiences of caregivers based on care recipient diagnosis is limited. The aim of this study was to examine the impact of worry and feelings of vigilance among caregivers of people with cognitive impairment due to either TBI or dementia. This sample included 61 caregivers (88.5% female, mean age 57.3 ± 15.5) of persons with either a TBI (n = 32) or dementia (n = 29). Worry was assessed with the Penn State Worry Questionnaire and Vigilance was assessed with the Caregiver Vigilance Scale. Linear regressions revealed that after controlling for age, care recipient diagnosis moderated the relationship between worry and caregiver vigilance. Specifically, worry was significantly associated with caregiver vigilance in those caring for someone with dementia; however, a similar relationship was not seen in those caring for someone with a TBI. This suggests caregivers of people with TBIs have a different experience of worry and vigilance than caregivers of people with dementia. These findings demonstrate the need for more research on the unique needs of caregivers of people with TBIs. Additionally, this research suggests interventions targeting worry may be particularly effective in supporting caregivers of people with TBIs.

COGNITIVE DECLINE AND RETIREMENT: FINDINGS FROM THE CANADIAN LONGITUDINAL STUDY ON AGING

Catherine Gosselin,¹ Meghan Désilets-Jutras,² and Benjamin Boller,³ 1. *Université du Québec à Trois-Rivières, Trois-Rivières, Quebec, Canada*, 2. *Université du Québec à Trois-Rivières, Université du Québec à Trois-Rivières, Quebec, Canada*, 3. *Université du Québec à Trois-Rivières, Université du Québec à Trois-Rivières, Quebec, Canada*

Since increasing life expectancy leads to a longer period of retirement, several studies have been investigating the possible impact of retirement on cognitive health. Several epidemiological studies with cross-sectional designs have reported a negative association between retirement and cognitive capacities. However, very few studies with longitudinal designs have confirmed the negative effect of retirement on cognitive functioning. The present study was conducted to investigate the impact of retirement on cognitive capacities among older Canadians. We used data from the Comprehensive cohort of the Canadian Longitudinal Study on Aging (CLSA) to compare performance retirees and workers (N = 1442), 45 to 85 years of age at baseline. Memory and executive functioning were assessed using standardized assessment tools at baseline and at three-year follow up. Retirees and workers were matched for age, gender and education using the nearest neighbor propensity score method with a caliper of 0.02. Mixed ANOVA and post hoc analyses were conducted separately for the English- and French-speaking samples. Results for the English-speaking sample showed a significant decline on both the Stroop and the Mental Alternation Task for retirees compared to workers from baseline to follow-up. These results support previous cross-sectional studies that have demonstrated a negative effect of retirement on executive functioning. The absence of significant results in the French-speaking sample will be discussed in terms of sample size and professional occupation.

COMBATING SOCIAL ISOLATION AMONG OLDER IMMIGRANT ADULTS: A QUALITATIVE INTERPRETIVE META-SYNTHESIS

Vivian Miller,¹ Betty Tonui,² and Dolapo Adeniji,³ 1. *Bowling Green State University, Bowling Green, Ohio, United States*, 2. *Oakland University, Oakland University Rochester, Michigan, United States*, 3. *IUPUI, Avon, Indiana, United States*

Older immigrants totaled 7.3 million in 2018, representing 13.9 percent of the population of seniors in the U.S. While this population is found to contribute significantly to society, along with new opportunities comes circumstantial challenges. Of these, one of the most salient issues for foreign-born older adults is social isolation. Additionally, this population may be at an increased risk for social isolation with poor mental health because migrating to a new country might result in resettlement challenges. Despite these concerns, less is known about the consequences of social isolation among older immigrant adults. Guided by the Population Interest Context (PICO) framework and the Qualitative Interpretive Meta-Synthesis (QIMS) guidelines, this study seeks to explore consequences of social isolation among older immigrant, as well as interventions to combat isolation. The final sample of six full text articles were published between 2011 and 2021, totaling 180 participants with ages ranging from 61 to

93 years old. Findings from the study indicated that older immigrants are at risk of social isolation and loneliness because they have fewer social connections due to leaving behind their familiar social group in the home country, encounter linguistic challenges that negatively contribute to greater social isolation and poor mental health. Despite these difficulties older immigrants reported various social interventions, i.e., access to senior centers, community programs and services to be of greater importance in building social networks. Authors discuss opportunities for future research, such as exploring evidence-based studies on interventions for social isolation and loneliness of older immigrant populations.

CONCEPTUALIZING THE VALUE OF AGING: WHAT IS IT LIKE TO BE AN OLDER WOMAN IN THE 21ST CENTURY?

Karen Shilvock-Cinefro, *George Williams College/Aurora University*

The basis for this hermeneutic phenomenological research was to identify common themes in women 65 years of age and older and determine whether these women felt valued in ageing. The best description of this research becomes the study of the phenomena as real living or “entering the lifeworld” (Finlay, 2012). The research sought to increase the knowledge of how older women feel about their own ageing and the effect of society’s response to them. The participants covered a large age range of 66 to 93 years of age all of which experienced physical, emotional, and social changes involving age. The participants’ response to these changes of ageing and society’s response to them ranged from very positive to very distressing. Twelve women were interviewed from a vast range of locations throughout the United States through zoom due to COVID 19. Their responses reflect four main categories: ageism, successful ageing, active engagement, and social support. The interviews focused on seven main questions: Tell me about being your age? Is there a time you can recall when you first felt older? Have you ever felt mistreated as an older adult? Have you ever felt you were discounted or ignored as being an older woman? Have you done anything to maintain your youth? Have you done anything to feel youthful? Have you ever felt dismissed related to your age? Utilizing seven questions and the conversation with these questions brought forth this study. This became a platform for these women to tell their stories.

CORESIDENCE INCREASES RISK OF TESTING POSITIVE FOR COVID-19 AMONG OLDER BRAZILIANS

Flavia Andrade,¹ Nekehia Quashie,² and Luisa Schwartzman,³
1. *University of Illinois--Urbana-Champaign, Urbana, Illinois, United States*, 2. *Technical University of Dortmund, Dortmund, Nordrhein-Westfalen, Germany*, 3. *University of Toronto, Mississauga, Ontario, Canada*

Brazil is among the countries hit hardest by COVID-19, and older adults are among the vulnerable groups. Intergenerational coresidence and interdependence among family members, both prevalent in Brazil, likely increase social and physical contact. Using nationally representative data from the COVID-19 module of the Brazilian National Household Sample Survey, collected from July to November of 2020, we examined the association between living arrangements and exposure to and testing for COVID-19 among 63,816 Brazilians 60+. Our multivariate analyses utilize

multilevel mixed-effects Poisson regression to examine the association between living arrangements and the COVID-19 outcome measures. Results show that those living alone were more likely to report having symptoms and having had a test for COVID-19. However, older adults in multigenerational (PR=1.532, 95% CI 1.15, 2.04, $p < 0.001$) and skipped generation households (PR=1.607, 95% CI 1.04, 2.48, $p < 0.001$) were more likely than solo-dwellers to test positive for COVID-19. Those with symptoms were more likely to test, regardless of their living arrangement. Among older adults without symptoms, those living alone had a higher probability of testing than those living in multigenerational or skipped-generation households. Overall, our findings suggest that coresidence with younger family members is a risk factor for older adults’ health due to the higher COVID-19 positivity. As younger Brazilians are increasingly vulnerable to COVID-19 and experiencing severe outcomes, policy makers need to be more attentive to the health needs of households that comprise older and younger cohorts, which are also more prevalent in poor and marginalized segments of the population.

DEMENTIA READY: COMPARING APPROACHES FOR BUILDING CAREGIVER READINESS AND KNOWLEDGE OF DEMENTIA

Michael Lepore,¹ Kate Keefe,² Erica DeFrancesco,² Julie Robison,³ Alis Ohlheiser,⁴ Christine Bailey,⁵ and Kathy Kellett,⁴ 1. *LiveWell Alliance, Southington, Connecticut, United States*, 2. *LiveWell, Plantsville, Connecticut, United States*, 3. *University of Connecticut, University of Connecticut, Connecticut, United States*, 4. *UConn Health, Farmington, Connecticut, United States*, 5. *University of Connecticut Health Center, Farmington, Connecticut, United States*

Despite the rising prevalence of dementia and the high cost and complexity of care for people with dementia, most dementia care is provided at home by informal caregivers who are not clinically trained. Building caregiver readiness and knowledge of dementia is key to supporting quality care and desirable health outcomes, such as preventing falls and reducing nursing home admissions. We sought to determine and compare the impact of two interventions—Resilient Living with Dementia (RLWD) and Care of Persons with Dementia in their Environments (COPE)—and of their combined delivery (both RLWD and COPE) on increasing caregiver readiness and knowledge of dementia. Between January 2019 and March 2021, 77 caregivers of people with dementia in Connecticut participated in RLWD and/or COPE and completed the Alzheimer’s Disease Knowledge Scale (ADKS) and the Preparedness for Caregiving Scale (PCGS) at baseline and at four-month and ten-month follow-ups. Analyses were conducted to compare outcomes by intervention(s). From baseline to four months and to ten months, we observed statistically significant ($p < .05$) improvement on the ADKS among participants in RLWD, and on the PCGS among participants in COPE and among participants in RLWD. The most substantial impact on PCGS was observed among participants in both COPE and RLWD. No improvement in the ADKS was observed among participants in only COPE, but ADKS improvement was observed at four months among participants in COPE and RLWD. Findings suggest that the benefits of COPE and RLWD for building dementia caregiver readiness are complementary and mutually reinforcing.

DEMENTIA RISK IN OLDER VETERANS WITH FRAILITY: A CROSS-SECTIONAL STUDY

Christian Gomez Hernandez,¹ Alma Diaz,² Ahmadou Sow,² Gauty Athouriste,² Ezekiel Ijaopo,³ and Jorge Ruiz,⁴ 1. *Miami VA Healthcare System, Miami, Florida, United States*, 2. *Miami VAMC, Miami, Florida, United States*, 3. *University of Miami/Jackson Health System, Miami, Florida, United States*, 4. *VAMC, Miami, Florida, United States*

Frailty, a clinical syndrome characterized by vulnerability to stressors resulting from multisystemic loss of physiological reserve, predicts future cognitive decline. However, frailty has also been proposed as a dementia risk factor, predicting future cognitive impairment. The study aim was to determine frailty in older veterans and its association with risk of dementia. Community-dwelling Veterans ≥ 50 years completed a mailed socio-demographic questionnaire and Self-Administered Gerocognitive Examination (SAGE), July 2019-May 2020. The information was complemented with EHR data. We calculated the CAIDE score, a validated tool predicting dementia (≥ 6 points= high risk 20 years later) and the 31-item VA frailty index data (frail $\geq .20$, non-frail $\leq .20$). After adjusting for socio-demographic characteristics, smoking, alcohol/substance abuse, OSA and anticholinergic use, odds ratio (OR) and 95% CI were calculated using BLR to assess the cross-sectional association between frailty and dementia risk (CAIDE ≥ 6 points and MCI). The survey response rate was 19.75% (1,073 of 5,432). Participants mean age was 68.38 (SD=8.49) years, 57.50% (n=617) Caucasian, 69.34% (n=744) non-Hispanic, 95.81% (n=1,028) male, and 36.72% (n=394) frail. 11.84% (n=127) screened positive for MCI and 15.38% (n=165) for dementia. 689 (75.88%) veterans were at high risk for dementia of whom 426 (61.83%) were non-frail and 263 (38.17%) were frail. Frailty was cross-sectionally associated with higher risk for dementia in older Veterans, adjusted OR:1.45 (95%CI:1.016-2.070), $p=.041$. The mailed screening was a feasible and practical approach to screen for dementia risk. Early identification of patients with frailty can help in the implementation of interventions aimed at preventing or delaying dementia.

DEPRESSION MEDIATES THE CAUSAL EFFECT OF FOOD INSECURITY TRANSITION ON COGNITIVE FUNCTION

Peiyi Lu,¹ Katrina Kezios,² and Adina Zeki Al Hazzouri,² 1. *Columbia University, Fort Lee, New Jersey, United States*, 2. *Columbia University, New York, New York, United States*

Despite substantial evidence on the relationship between food insecurity and worse cognition, few studies have examined the underlying mechanisms. This study examined whether and to what extent depression mediated the causal effect of food insecurity on cognition in midlife. Longitudinal data from the Coronary Artery Risk Development in Young Adults Study were used. The 2000 survey was used as our study's baseline, when respondents aged 33-45. We lagged the explanatory and mediator variables to set up temporality. Food insecurity transition from 2000-2005 surveys was recoded (persistent food secure, persistent food insecure, became food insecure, and became food secure). Depression was measured in 2010, while cognitive functions were measured in 2015. Causal mediation analysis examined

and decomposed the direct and indirect effect. Compared to persistent food security, both persistent and became food insecure were linked to worse cognition, after adjusting demographic and cardiovascular risk factors. Further, for both exposure groups, depression had significant and strong mediation effects (natural indirect effect ranged from -0.037 to -0.018). Specifically, as respondents experienced persistent food insecurity or became food insecure, their depression increased, which, in turn, reduced their cognition. The proportion of the total effect of food insecurity transition on cognition mediated by depression ranged from 7-24% for processing speed, verbal memory, cognitive, and language functions. Persistent and became food insecure reduced cognitive function directly or indirectly through increasing depression among middle-aged adults. Interventions targeting either food insecurity or treatment of depression among food insecure individuals may have the potential to slow premature cognitive aging.

DESIGNING A GENETIC SCREEN TO IDENTIFY FACTORS REQUIRED FOR MEIOTIC NUCLEAR REJUVENATION

Chelsey Jones, *Howard University, Hyattsville, Maryland, United States*

During the natural cycle of life, most eukaryotic organisms grow old, age, and die. A common natural mechanism by which organisms "reset" their lifespan is through sexual reproduction; however, how this rejuvenation takes place remains unknown. My lab has found that meiosis in budding yeast, the developmental program that forms sex cells, eliminates age-induced damage. This involves the formation of a novel nuclear compartment, the Gametogenesis Uninherited Nuclear Compartment (GUNC), which acts as a trash can for accumulated age-induced damage. To understand the molecular details of this process, I worked on designing a screen for genes involved in GUNC formation. My mentor and I fused three different proteins targeted to the GUNC and a protein that is able to bind to a drug-resistance plasmid, in order to couple the inheritance of a selectable DNA marker with the elimination of age-induced damage. Initial testing of these three fusion proteins suggested that they were unable to successfully target the plasmid to the GUNC; as such, testing of additional candidate proteins is necessary. We plan to eventually use this system to identify mutations that disrupt GUNC formation and cause inheritance of the drug-resistance plasmid. By identifying and perturbing proteins involved in GUNC formation, we are hoping to be able to drive the inheritance of specific types of age-induced damage, allowing for the determination of what a symptom versus a cause of aging is.

DIABETES, OBESITY, AND OSTEOPOROSIS IN AN ETHNICALLY DIVERSE POPULATION OF WOMEN RECEIVING OSTEOPOROSIS SCREENING

Feven Kahsay,¹ Wendy Yang,² Malini Chandra,³ Catherine Lee,⁴ Nailah Thompson,⁴ and Joan Lo,⁴ 1. *McGovern Medical School, Houston, Texas, United States*, 2. *The Permanente Medical Group, San Jose, California, United States*, 3. *Kaiser Permanente Northern California,*

Oakland, California, United States, 4. The Permanente Medical Group, Oakland, California, United States

Osteoporosis screening by bone density (BMD) testing is recommended for women aged 65-75 years. However, patients with diabetes, a risk factor for fracture, often have higher body mass index (BMI) which contributes to higher BMD. These factors may vary by race/ethnicity. The relationship of diabetes (≥ 2 diagnoses and treatment), obesity (BMI ≥ 30), and BMD-defined osteoporosis (femoral neck BMD T-score ≤ -2.5) was examined in a diverse primary care population of 44,313 non-Hispanic White, 6,103 Black, 7,777 Hispanic, and 12,634 Asian women aged 65-75 years who underwent BMD screening. Those with recent fracture, osteoporosis treatment, bone disorders, and metastatic cancer were excluded. Modified log-Poisson regression was used to examine the association of diabetes and BMD-osteoporosis. Among 70,827 women, 18% had diabetes. The prevalence of diabetes was 2-fold higher in Black, Hispanic and Asian women compared to White women. Overall, women with diabetes (versus no diabetes) were more likely to be obese and, except for Hispanic women, less likely to have BMD-osteoporosis. In unadjusted analyses, diabetes was associated with lower risk of BMD-defined osteoporosis in White, Black, and Asian women, but not Hispanic women. However, the association was attenuated or no longer evident after adjusting for BMI, suggesting that the lower burden of BMD-osteoporosis in women with diabetes is mediated in part by higher BMI. These findings support consideration of diabetes when assessing fracture risk in women undergoing osteoporosis screening. However, more studies in non-White populations with a high burden of diabetes are important since these relationships appear to differ by race/ethnicity.

DO INFLAMMATION MARKERS MODERATE ASSOCIATIONS BETWEEN CAREGIVING AND QUALITY OF LIFE, HEALTH, AND DEPRESSION?

Elizabeth Orsega-Smith,¹ Marie Kuczmarzski,² Adam Davey,¹ Brianna Wolfe,¹ Alan Zonderman,³ and Michele Evans,²

1. *University of Delaware, Newark, Delaware, United States,*
2. *National Institutes of Health, Baltimore, Maryland, United States,*
3. *NIA, NIA, Maryland, United States*

Caregiving responsibilities can put stress and strain on older adults including emotional distress, depression, decline in physical functioning, and decreased self-reported quality of life. Chronic stress such as from caregiving may be related to chronic inflammation, but this has been less widely examined. Therefore, the purpose of this study is to examine whether the association between caregiving and outcomes including quality of life indicators, self-rated health, and depressive symptoms are moderated by physical activity, stress coping, diet quality inflammatory index, and selected biomarkers of inflammation. We used data from waves 3 and 4 of the Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study. In wave 3, 733 reported caregiving for grandchildren. They were mostly African American (59%) and female (55%) with a mean age was 47.7 years at the start of the study. In linear regression models, caregiving for grandchildren (CGC) predicted higher depressive symptoms and lower quality of life and self-rated health. Results demonstrated that the association between erythrocytes sedimentation rate (ESR) was a significant moderator between CGC and quality of life, self-rated health, and depressive

symptoms ($p < 0.05$). In a separate analysis of wave 4 data (152 reported caregiving for elders), serum magnesium was a significant moderator between caregiving for elders and both quality of life and self-rated health ($p < 0.05$). These results suggest that inflammatory factors may influence the health of diverse older adult caregivers. Further (or Future) research may evaluate the effect of these moderators over time.

DOES FRAILTY INFLUENCE INHOSPITAL MANAGEMENT AND OUTCOMES OF COVID-19 IN OLDER ADULTS IN THE US?

Soko Setoguchi,¹ Vithal Madhira,² Timothy Bergquist,³ Nathaniel Kuhrt,⁴ Jessica Islam,⁵ Heidi Spratt,⁶ Joseph Siu,⁷ and Richard Kennedy,⁸ 1. *Rutgers Robert Wood Johnson Medical School, New Brunswick, New Jersey, United States,* 2. *Palila Software LLC, Palila Software LLC, Nevada, United States,* 3. *Sage Bionetworks, Kent, Washington, United States,* 4. *New Jersey Medical School, Newark, New Jersey, United States,* 5. *H. Lee Moffitt Cancer Center and Research Institute, Tampa, Florida, United States,* 6. *University of Texas Medical Branch, Galveston, Texas, United States,* 7. *University of Nebraska Medical Center, Omaha, Nebraska, United States,* 8. *University of Alabama at Birmingham, Birmingham, Alabama, United States*

Older age has been consistently associated with adverse COVID-19 outcomes. Frailty, a syndrome characterized by declining function across multiple body systems is common in older adults and may increase vulnerability to adverse outcomes among COVID-19 patients. However, the impacts of frailty on COVID-19 management, severity, or outcomes have not been well characterized in a large, representative US population. Using the National COVID Cohort Collaborative, a multi-institutional US repository for COVID-19 research, we calculated the Hospital Frailty Risk Score (HFRS), a validated EHR-based frailty score, among COVID-19 inpatients age ≥ 65 . We examined patient demographics and comorbidities, length of stay (LOS), systemic corticosteroid and remdesivir use, ICU admission, and inpatient mortality across subgroups by HFRS score. Among 58,964 inpatients from 53 institutions (51% male, 65% White, 18% Black, 9% Hispanic, mean age 75, mean Charlson comorbidity count 3.0, and median LOS 7 days), 38,692 (66%), 4,180 (7%), 3,531 (6%), 3,525 (6%) and 7,862 (13%) had HFRS scores of 0-1, 2, 3, 4, and ≥ 5 , respectively. Frailty was only moderately correlated with age and comorbidity ($\rho = 0.178$ and 0.348 , respectively, $p < 0.001$). Overall, 34% received systemic corticosteroid and 19% received remdesivir. We observed 4% ICU admissions and 16% inpatient death. Among non-ICU admissions, after adjusting for demographics and comorbidities, frailty (HFRS ≥ 2) was associated with 79% greater systemic corticosteroid use and 22% greater remdesivir use, whereas a higher HFRS score was marginally associated with higher rates of severe COVID disease, inpatient death, or ICU admission.

DURATION OF REPRODUCTIVE PERIOD AND RISK OF TRANSITIONING TO MILD COGNITIVE IMPAIRMENT AND DEMENTIA

Tomiko Yoneda,¹ Jamie Knight,¹ Nathan Lewis,¹ Graciela Muniz-Terrera,² David Bennett,³ and Andrea Piccinin,¹ 1. *University of Victoria, Victoria, British Columbia, Canada,* 2. *University of Edinburgh, Edinburgh,*

Scotland, United Kingdom, 3. Rush University, Chicago, Illinois, United States

Decreasing estrogen levels have been hypothesized to be associated with increased risk of dementia, yet the current literature reveals conflicting results. This study aimed to determine whether a longer reproductive period, as an indicator of longer exposure to endogenous estrogens, is associated with risk of transitioning to MCI and dementia. Women 65 and over (N=1507) from the Rush Memory and Aging Project met eligibility for the current analysis. The average length of reproductive period (menopause age minus menarche age) was 35 years (range=16-68 years), and 64% had natural menopause. Multistate survival modeling (MSM) was used to estimate the influence of reproductive period on risk of transitioning through cognitive states including mild cognitive impairment (MCI) and clinically diagnosed dementia, as well as death. Multinomial regression models estimated total and cognitively unimpaired life expectancies based on the transition probabilities estimated by the MSM. Results suggest that women with more reproductive years were less likely to transition from no cognitive impairment (NCI) to MCI, and were more likely to return to NCI from MCI. Analyses also suggest two additional years free of cognitive impairment for women with 45 vs 25 years of reproduction, though reproduction period did not significantly impact overall life expectancy. This study suggests that the number of years of reproductive duration is not associated with the transition to dementia, but is possibly associated with delayed cognitive decline, reduced risk of MCI, increased likelihood of returning to NCI from MCI, and increased lifespan free of cognitive impairment.

EFFECTIVENESS OF A STAFF TRAINING PROGRAM TO STIMULATE PHYSICAL ACTIVITY IN HOMECARE: A CLUSTER RCT

Silke Metzelthin,¹ Teuni H Rooijackers,¹ GA Rixt Zijlstra,¹ Erik van Rossum,² Annemarie Koster,¹ Silvia Evers,³ Valeria Lima Passos,¹ and Gertrudis IJM Kempen,¹ 1. Maastricht University, Maastricht, Limburg, Netherlands, 2. Zuyd University of Applied Sciences, Maastricht, Limburg, Netherlands, 3. m, Maastricht, Limburg, Netherlands

Reablement encourages older adults to do things themselves rather than having things done for them. To implement reablement in practice homecare staff needs the right knowledge, attitude, skills and support. This study evaluated the effectiveness of the “Stay Active at Home” reablement training program. A 12-month cluster-RCT was conducted, involving staff (n=313) and clients (n=264) from 10 homecare teams, five of which were trained. Effects were evaluated using data from accelerometers, physical performance tests, questionnaires and electronic patient records. No beneficial effects were observed in older adults for sedentary behavior; daily, physical, and psychological functioning; and falls. In homecare staff there were no statistically significant differences between study groups for self-efficacy and outcome expectations scores except for higher self-efficacy scores in more compliant staff (adjusted mean difference: 1.9 [95% CI 0.1, 3.7]). No differences were observed for any cost category except for domestic help costs in the intervention group (adjusted mean difference: €-173 [95% CI -299, -50]). The probability that “Stay Active at Home” is cost-effective

compared to usual care at a willingness-to-pay of €20,000 was 19.7%/ daily minute of sedentary time averted, 19.2%/ percent of sedentary time averted as proportion of wake/wear time, and 5.9%/QALY gained, respectively. The reablement training program needs further development based on the lessons learned before wider implementation.

EFFECTS OF TINNITUS ON COGNITION AND DEPRESSIVE SYMPTOMS OVER TIME

Jennifer De Anda,¹ Teresa Warren,¹ Tyler Bell,² William Kremen,² and Carol Franz,² 1. San Diego State University, San Diego, California, United States, 2. University of California San Diego, La Jolla, California, United States

Evidence suggests links among tinnitus, depression, and cognition. We examined these associations over time. We hypothesized baseline tinnitus would predict poorer cognitive performance and more depressive symptoms an average of 11.4 years later. We examined 839 men at two timepoints (baseline age M=55.94; follow-up age M=67.56). At each time point participants responded yes/no if they had tinnitus. We created three tinnitus status groups – no tinnitus at either time, tinnitus at both, and no tinnitus at baseline but tinnitus at follow-up. At both time points we measured cognitive performance with tests of episodic memory, processing speed, executive function, and verbal fluency. Depressive symptoms were based on the Center for Epidemiological Studies Depression scale. There was no association between tinnitus and any measure of cognitive performance. Depressive symptoms declined from baseline to follow-up. In separate mixed models predicting depressive symptoms, there was a significant main effect for tinnitus status at baseline ($p = .003$) and follow-up ($p < .001$). Those with tinnitus at both times had significantly higher depressive symptoms than the “No tinnitus” group ($p < .001$). This association remained significant after accounting for baseline depressive symptoms ($p = .011$) at follow-up. Results did not support the hypothesis that tinnitus would be associated with poorer cognitive function. However, depressive symptoms declined among those with no tinnitus than the other groups. The relationship between tinnitus and depressive symptoms may have implications for future cognitive performance among older adults, given previous evidence that depressive symptoms are risk factors for cognitive decline.

ENGAGING WITH AGING: A QUALITATIVE STUDY OF AGE-RELATED CHANGES AND ADAPTATIONS

Shaoqing Ge,¹ Kuan-Ching Wu,² Hillary Frey,³ Maryam Saudagaran,³ Derick Welsh,³ Janet Primomo,⁴ and Basia Belza,⁵ 1. University of Washington School of Nursing, Seattle, Washington, United States, 2. University of Washington School of Nursing, University of Washington School of Nursing, Washington, United States, 3. University of Washington School of Nursing, University of Washington, Washington, United States, 4. University of Washington Tacoma School of Nursing & Healthcare Leadership, University of Washington Tacoma, Washington, United States, 5. University of Washington, Seattle, Washington, United States

Engaging with Aging is an emerging framework proposed by Carnevali which provides a new lens to understand

an active, conscious daily living process of coping with age-related changes (ARCs) taken on by older adults. Study aims were to 1) describe the ARCs experienced by community-dwelling older adults; 2) identify the strategies and resources used by older adults to accommodate the daily living challenges caused by the associated ARCs; and 3) evaluate the framework of EWA based on findings from aims 1 and 2. We conducted semi-structured interviews with 29 participants aged 64 to 98 online due to COVID-19 restrictions. We used a virtual card sort to assist data gathering. Fifteen ARCs (e.g., changes in hearing, changes in stability, changes in sleep, etc.) were mentioned by participants and their corresponding adaptations were discussed. We found that older adults linked their adaptations to their ARCs based on their changing capacities and needs. Commonly used adaptations included conserving energy, utilizing tools or technology, and being more conscious before and while taking actions. The challenges caused by COVID-19 in implementing the adaptations were also discussed (e.g., increased difficulty in understanding others due to mask-wearing). Our study substantiates the EWA framework by showing the commonality among older adults in linking ARCs with adaptations. Implications for clinicians and researchers include using EWA to help older adults identify personalized solutions that fit their capacities. Our study is late-breaking as we recently finished data analysis and the information included was not yet available by the previous submission deadline.

EXPERIENCES OF AFRICAN AMERICAN DEMENTIA CAREGIVERS DURING THE COVID-19 PANDEMIC

Sloan Oliver,¹ Karah Alexander,² and Fayron Epps,¹

1. *Emory University, Atlanta, Georgia, United States*,
2. *Nell Hodgson Woodruff School of Nursing at Emory University, Atlanta, Georgia, United States*

African American caregivers are often confronted with the complexities of caregiving through the lens of race and associated health disparities. The COVID-19 pandemic has both exacerbated the systemic disparities and deeply rooted inequities experienced by African Americans and laid bare their effects on the community of caregivers. The purpose of this project was to explore the experiences of African American dementia caregivers during the COVID-19 pandemic. Nineteen African American caregivers of persons living with dementia were recruited by primary investigators and community partners with purposeful sampling techniques to participate in semi-structured focus groups that were held April 2021. Four overarching themes were constructed during thematic analysis: social isolation, decreased well-being, the good and bad of telehealth, and challenges in fulfilling the caregiver role. Caregivers expressed that they became socially isolated from family and friends, which led to them becoming depressed and mentally strained. Several caregivers felt they could not carry out their caregiver duties due to the constraints surrounding the pandemic. The varying levels of interaction with and the comfort level of physicians utilizing telehealth led to caregivers having mixed reviews on the popularized service. The results of this study will be used to culturally adapt caregiving education courses and programs promoting mastery and competency during a pandemic. In preparations for future public health crises, healthcare professionals will be able to use the results of this

study to address the specific needs and improve the experiences of African American dementia caregivers.

FACTORS ASSOCIATED WITH OLDER PEOPLES' PERCEPTIONS OF DIGNITY AND WELL-BEING AT RESIDENTIAL CARE FACILITIES.

Charlotte Roos,¹ Moudud Alam,² Anna Swall,¹ Anne-Marie Boström,³ and Lena Hammar,⁴ 1. *Dalarna University, Falun, Dalarnas Lan, Sweden*, 2. *Dalarna University, Borlänge, Dalarnas Lan, Sweden*, 3. *Karolinska Institutet, Karolinska Institute, Stockholms Lan, Sweden*, 4. *Mälardalen University / Dalarna University, Västerås, Vastmanlands Lan, Sweden*

Dignity and well-being should be promoted in care of older people living at residential care facilities (RCFs). In addition, care should be person-centred. Dignity and well-being can be interpreted as person-centred outcomes. Older people living at RCFs experience a lack of dignity and well-being. To promote this, it is important to understand the associated factors to target. The aim of this study was to examine the associations between perceived dignity and well-being and factors related to attitudes of staff, the care environment and individual issues (age, gender, self-rated health and dementia) among older people living at RCFs. A national cross-sectional study was conducted retrospectively. All older people 65 years and older (n=71,696) living at RCFs in 2018 were invited to respond to the survey. The survey included the areas: self-rated health, indoor-outdoor-mealtime environment, performance of care, treatment from staff, safety, social activities, availability of staff and care in its entirety. Age, gender and diagnosed dementia were collected from two national databases. Data was analysed using ordinal logistic regression models. The result indicated that respondents who had experienced disrespectful treatment, who did not thrive in the indoor-outdoor-mealtime environment, who rated their health as poor and respondents with dementia had higher odds of being dissatisfied with dignity and well-being. There is a need to improve the prerequisites of staff regarding respectful attitudes and to improve the care environment. The Person-centred Practice framework, targeting the prerequisites of staff and the care environment, can be used as a theoretical framework for designing future improvements.

FAKE NEWS DETECTION IN AGING DURING THE ERA OF INFODEMIC

Didem Pehlivanoglu,¹ Tian Lin,¹ Kevin Chi,¹ Eliany Perez,¹ Rebecca Polk,¹ Barian Cahill,¹ Nichole Lighthall,² and Natalie Ebner,¹ 1. *University of Florida, Gainesville, Florida, United States*, 2. *University of Central Florida, Orlando, Florida, United States*

Increasing misinformation spread, including news about COVID-19, poses a threat to older adults but there is little empirical research on this population within the fake news literature. Embedded in the Changes in Integration for Social Decisions in Aging (CISDA) model, this study examined the role of (i) analytical reasoning; (ii) affect; and (iii) news consumption frequency, and their interplay with (iv) news content, in determining fake news detection in aging during the COVID-19 pandemic. Young (age range 18-35 years, M = 20.24, SD = 1.88) and older (age range 61-87 years,

M = 70.51, SD = 5.88) adults were randomly assigned to view COVID or non-COVID news articles, followed by measures of analytical reasoning, affect, and news consumption frequency. Comparable across young and older adults, fake news detection accuracy was higher for news unrelated to COVID, and non-COVID fake news detection was predicted by individual differences in analytic reasoning. Examination of chronological age effects further revealed that detection of fake news among older adults aged over 70 years depended on interactions between individual CISDA components and news content. Collectively, these findings suggest that age-related susceptibility to fake news may only be apparent in later stages of older adulthood, but vulnerabilities are context dependent. Our findings advance understanding of psychological mechanisms in fake news evaluation and empirically support CISDA in its application to fake news detection in aging.

FALLING BETWEEN THE CRACKS: EXPERIENCES OF BLACK DEMENTIA CAREGIVERS NAVIGATING U.S. HEALTH SYSTEMS

Karah Alexander,¹ Sloan Oliver,² and Fayron Epps,² 1. *Nell Hodgson Woodruff School of Nursing at Emory University, Atlanta, Georgia, United States*, 2. *Emory University, Atlanta, Georgia, United States*

In addition to numerous care responsibilities, family caregivers are expected to navigate health systems and engage in healthcare management tasks on behalf of their persons living with dementia (PLWD). These challenging tasks pose additional difficulties for Black dementia caregivers. Due to the centuries-old, disadvantaged social history of Black Americans, several unique stressors, vulnerabilities, and resources have emerged which inform and affect Black dementia caregivers' experiences and well-being. Focus groups were held with Black caregivers (N = 19) from the United States (U.S.) to explore the unique experiences and perspectives of this population navigating the U.S. health system on behalf of their PLWD. Five overarching themes were developed during thematic analysis: Forced Advocacy, Poor Provider Interaction, Payor Source Dictates Care, Discrimination, and Broken Health System. Black dementia caregivers unanimously concurred that the health system that they experience in America is "broken." Gaps in the health system can lead to people [as one caregiver passionately expressed] "falling between the cracks," in terms of care, services, and resources needed. Caregivers agreed that class, sex, utilizing public health insurance, and being a "person of color" contribute to their difficulties navigating the health system. Caregivers perceived being dismissed by providers, forcing them to advocate for both themselves and their PLWD. Healthcare providers and researchers can utilize these findings to improve the experiences and healthcare outcomes of Black patients with dementia and their caregivers. Additionally, these findings can lead to the development of culturally tailored caregiver education programs.

FEAR, RESISTANCE, OR ANTICIPATION? OLDER TRUCK DRIVERS' REACTIONS TO THE ADOPTION OF AUTOMATED VEHICLES

Amy Schuster,¹ Jenna Van Fossen,² Danielle Sperry,¹ and Shelia Cotten,¹ 1. *Clemson University, Clemson, South*

Carolina, United States, 2. *Michigan State University, East Lansing, Michigan, United States*

The forecasted adoption of autonomous vehicles (AVs) will lead to major changes to the job of truck driving. These changes may be particularly challenging for drivers, as the population of truck drivers skews much older than that of other occupations. In this study we sought to understand truck drivers' attitudes towards AVs and the longevity of their job. We conducted focus groups with truck drivers, their supervisors, and upper-level managers of trucking companies. We relate supervisors' and managers' experiences working with drivers through the rollout of new technologies to further understand drivers' initial reactions to automation and how their attitudes may develop. Based on qualitative open coding our analysis uncovered two overarching themes. The first theme is the unknown. With AVs, companies expect that experience will be less important, so they can hire younger workers. In response, drivers have expressed fear of being displaced and anxiety over the uncertainty of not knowing how their jobs will be affected. The second theme is adaptability, and desire to adapt. Older drivers have expressed resistance to adapting to AVs and to their job changing. Concerningly however, managers envision the need for a driving workforce that has experience working with technology and is adaptable. Our study identifies key challenges concerning older workers' reactions and career decisions in response to automation. Accounting for driver reactions to AVs is necessary not only to build theory and understanding on worker reactions to automation, but also for workforce planning and to support employees, particularly older workers.

FEASIBILITY, ACCEPTABILITY, AND IMPACT OF A SELF-GUIDED E-LEARNING MEMORY PROGRAM FOR OLDER ADULTS

Danielle D'Amico,¹ Iris Yusupov,² Lynn Zhu,³ Jordan Lass,³ Cindy Plunkett,⁴ Brian Levine,³ Angela Troyer,³ and Susan Vander Morris,³ 1. *Ryerson University, Toronto, Ontario, Canada*, 2. *York University, Toronto, Ontario, Canada*, 3. *Baycrest, Toronto, Ontario, Canada*, 4. *Baycrest, North York, Ontario, Canada*

Clinician-led memory interventions have been shown to increase knowledge, reduce anxiety, promote memory-strategy use, and increase brain-healthy lifestyle behaviours in older adults with normal age-related memory changes. A self-guided, e-learning version of the Baycrest Memory and Aging Program® was recently developed to increase accessibility to memory interventions. The objectives of the current study were to assess program feasibility (retention rate), acceptability (satisfaction), and participant-reported impact (memory concerns, behaviour change, goal attainment). As part of a larger study, participants were 139 healthy older adults (mean age: 73±7, 73% female). Ninety-two individuals completed the program (retention rate=66%). Anonymous feedback data indicated a high level of satisfaction with the program overall (98%), the pace and clarity of the learning modules (100%), and the organization and navigation of the interface (92%). Suggested improvements included offering more interaction with others and addressing minor platform glitches. There was a decrease in the level of concern about memory change, with 64% expressing concern at a level consistent with the Jessen et al. (2014) criteria for Subjective

Cognitive Decline at baseline, and 23% expressing the same at post-test. The majority of participants reported increases in using memory-strategies (63-97%) and lifestyle-promoting behaviours (40-72%). All participants reported moderate to high satisfaction with personal goal attainment. Results support feasibility, acceptability, and impact of a self-guided e-learning adaptation of memory intervention. E-learning tools may be a promising avenue to deliver accessible brain health promotion in later life, especially in the context of the shift to virtual care during and beyond COVID-19.

FORMATIVE EXAMINATION OF A MULTI-FOCUS EDUCATIONAL EXERGAME DESIGNED FOR OLDER ADULTS

Laurie Ruggiero,¹ Elizabeth Orsega-Smith,² and Roghayeh Barmaki,² 1. *University of Delaware, University of Delaware, Delaware, United States*, 2. *University of Delaware, Newark, Delaware, United States*

Exergames and digital health games have shown promising outcomes in older adults. Most games have had one focus (e.g., physical activity, cognitive functioning). We developed a demonstration version of a multi-focus educational exergame (i.e., healthy eating, physical activity, cognition) that builds on healthy aging theory. Community-engaged and mixed methods (e.g., surveys, focus groups) research approaches were used to examine preliminary game acceptability and usability. The game was demonstrated with 20 senior center members (95% female; 48% African American; 52% White; average age 64 years) and participants were able to play the game. The post-gameplay survey results support acceptability/usability of the game. For example, 87% of participants “agreed” or “strongly agreed” that they felt comfortable playing; the game instructions were clear; the text was readable; and gameplay was enjoyable. The majority also “agreed”/“strongly agreed” that the audio was appealing/helpful in playing the game (86%); sound quality was appropriate (78%); hand tracking was precise (57%), feedback on correct/incorrect responses was motivating (73%); they felt excited to get the correct answers (80%); they would play the game again (87%); and they would recommend it to a friend/family member (80%). When asked how often they would play it, the responses were: 33% five or more times/week; 27% three-four times/week; 20% one-two times/week; and 20% never. Observations and focus groups further clarified acceptability and identified areas for improvement (e.g., game instructions). Preliminary results support acceptability of this multi-component educational exergame with older adults and suggest the potential for future tailoring of this game.

FUNCTIONAL STATUS IN OLDER ADULTS WITH PERIPHERAL ARTERY DISEASE IN KOREA: A CROSS-SECTIONAL STUDY

Yesol Kim,¹ Mihui Kim,¹ Gi Wook Ryu,² and Mona Choi,¹ 1. *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*, 2. *Namseoul University, Cheonan, Ch'ungch'ong-namdo, Republic of Korea*

Peripheral artery disease (PAD) is a chronic, progressive atherosclerotic disease resulting in worse functional status. It is an important factor that affects mobility and quality of life in older adults with PAD. This study aimed to identify

the functional status and its associated factors of older adults diagnosed with PAD. We conducted a cross-sectional study among older adults aged 65 above diagnosed with PAD at a tertiary hospital in Seoul, Korea. Participants' functional status was measured using a Walking Impairment Questionnaire (WIQ) which consisted of distance, speed, and stair-climbing. We measured cardiac health behavior, social support, health perception, and clinical manifestation through self-administered questionnaires. Among 94 participants, the mean age was 74.98±6.21 years, and 91.5% were male. The mean score of WIQ was 0.59±0.30 out of 1; the mean scores for distance, speed, and stair-climbing of WIQ were 0.67±0.40, 0.45±0.27, and 0.64±0.37, respectively. Participants' functional status was significantly associated with age ($\beta=-0.012$, $P=.002$), sex ($\beta=-0.284$, $P=.001$), ulcers of the lower extremity (LE) ($\beta=-0.242$, $P=.031$), using a walking-assist device ($\beta=-0.240$, $P=.002$), walking difficulty due to pain of LE ($\beta=-0.142$, $P=.006$), and health behavior about physical activity ($\beta=0.099$, $P=.021$). This regression model predicted 53.5% of participants' functional status ($F=8.63$, $P<.001$). This study indicated that younger age, female, independent walking, no ulcers of LE, no walking difficulty, and higher physical activity behavior were significantly associated with better functional status in older adults with PAD. Therefore, healthcare professionals should develop and provide interventions to promote physical activity and alleviate symptoms to enhance functional status.

GENERATIVITY IN LIFE REVIEW: DISCOVERING LIFE LESSONS AND WISDOM IN NATURALISTIC INTERGENERATIONAL CONVERSATIONS

Patricia Chilton,¹ Cindy Woolverton,² Elizabeth Glisky,¹ Matthias Mehl,¹ and Matthew Grilli,¹ 1. *University of Arizona, Tucson, Arizona, United States*, 2. *Michael E. DeBakey VA Medical Center, Houston, Texas, United States*

According to the theory of generativity, one would expect older adults to inherently feature life lessons in naturalistic conversations with younger adults. Little though, is known about the process of these conversations, and to what extent they convey wisdom characteristics. In this project, intergenerational conversations between university students and older adults living in assisted and independent living communities were analyzed to identify life lessons within older adults' informal life reviews. In the original study, 37 young and 52 older adults engaged in an intergenerational interaction as part of an undergraduate course. These conversations were recorded with participants' consent, and transcribed with identifying information removed. For the current project, we analyzed 15 of these recorded conversations, averaging 46 minutes each between 10 students and 5 older adults to (1) develop a coding scheme and procedure to examine life lessons in intergenerational conversations, and (2) investigate whether wisdom characteristics are embedded into life lessons shared in this context. On average, each older adult referenced 4 life lessons ($SD = 2$) per conversation, which were coded for the following constructs: meaning making, personal growth, emotional valence, wisdom characteristics, life lesson type, and autobiographical memory type. Exploratory analyses suggest life lessons are inherently integrated into naturalistic intergenerational

conversations, and that reflectivity is the most frequently expressed wisdom characteristic. This supports previous research identifying reflectivity as key to wisdom, and to the process of generativity. Further analysis is needed to illuminate the value of intergenerational conversations, particularly in a time of age segregation and ageism.

IMPACT OF APOE GENOTYPE ON DIET-INDUCED MITOCHONDRIAL ADAPTATIONS IN MOUSE SKELETAL MUSCLE

Niaya James,¹ Oyinkansola Shonde,² Nahdia Jones,³ Verona E. Mulgrave,⁴ and G. William Rebeck,⁵ and Joanne Allard,¹ 1. *Howard University, Washington, District of Columbia, United States*, 2. *District of Columbia, United States*, 3. *Columbia University, Washington, District of Columbia, United States*, 4. *Delaware State University, Howard University, District of Columbia, United States*, 5. *Georgetown University Medical Center, Washington, District of Columbia, United States*

Apolipoprotein E (APOE), a component of lipoproteins that facilitates cholesterol transportation, has three variants in the human genome: APOE2, E3, and E4. Prior research found that carriers of APOE4 are more susceptible to developing Alzheimer's disease (AD) and other brain disorders than those who possess other APOE alleles, and that these carriers are also predisposed to mitochondrial impairment—an early characteristic of neuronal dysfunction. Peroxisome proliferator-activated receptor gamma coactivator-1 alpha (PGC-1 α) is a major biomarker for mitochondrial biogenesis and function and cytochrome c oxidase subunit IV (COX4) is the terminal enzyme of the mitochondrial respiratory chain. Decreased measures of these proteins indicate reduced mitochondrial function. Aside from genetic inheritance, lifestyle factors such as diet and exercise significantly impact one's risk for mitochondrial dysfunction and AD. In these studies, we examined the impact of APOE variance on physiological adaptations induced by either exercise or a high-fat diet, with a focus on biomarkers of mitochondrial function. Western blots were used to measure COX4 and PGC-1 α levels in skeletal muscle tissue from female APOE3 and APOE4 knock-in transgenic mice. Based on performance on a motorized rotating rod and voluntary wheel-running, we deduced that female APOE4 mice exhibit reduced motor coordination and activity relative to APOE3 mice. APOE4 mice also had reduced COX4 levels that were increased by the high-fat diet. In contrast, COX4 levels in APOE3 mice were reduced in the high-fat diet group. Our data show that diet and APOE genotype interact to produce adaptations in mitochondrial proteins in skeletal muscle.

IMPACT OF COVID-19 PANDEMIC ON MENTAL HEALTH, SOCIAL CONNECTEDNESS AND COGNITIVE PERFORMANCE OF OLDER ADULTS

Juliana Souza-Talarico,¹ Fernanda Silva,² Maria Clara Jesus,³ Breno JAP Barbosa,⁴ Ricardo Nitri,⁵ and Sonia MD Brucki,⁴ 1. *The University of Iowa, Iowa City, Iowa, United States*, 2. *School of Nursing, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil*, 3. *School of Nursing, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil*, 4. *Faculty of Medicine, University of Sao Paulo, Sao*

Paulo, Sao Paulo, Brazil, 5. *Faculty of Medicine, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil*

The COVID-19 pandemic has profoundly impacted older adult's health and well-being worldwide. We explored the impact of the COVID-19 pandemic on daily activities and mental health and its relationship with cognitive performance in older adults. Methods: One-hundred individuals 60 years and older, without cognitive impairment and enrolled in the Brazilian Memory Study (BRAMS), a longitudinal study, were applied the UCLA Loneliness Scale, Perceived Stress Scale (PSS), Geriatric Depression Scale (GDS), and Mini-Mental State Examination (MMSE). Participants were asked whether they had changes in daily routine and social connectedness during the pandemic. Results: Almost half of the participants (48.4%) reported that the COVID-19 pandemic significantly affected their lives, 38.9% lost a relative or friend because of COVID-19, and 60% had daily routine changes. Relationships (40.5%) and emotion (22%) were reported as the most impacted area. Stopping physical activities and stay at home represented the main routine changed for 78% of participants. The use of voice messages through mobile phones to maintain social connectedness increased from 24.2% to 42.1%. For 38% of participants, their autonomy to daily decisions decreased, and 40% complained that memory got worse during the pandemic. More than 30% felt more stress, loneliness, or depression than in the pre-pandemic period. Controlling for age, sex, and education, higher loneliness scores were significantly associated with low MMSE scores ($p = 0.018$). Conclusion: Significant changes in life, daily routine, social connectedness, and mental health-related to the COVID-19 pandemic were reported by older adult participants. Loneliness was associated with lower cognitive performance.

IMPACT OF NEIGHBORHOOD SOCIOECONOMIC DISADVANTAGE ON STAFFING HOURS IN US NURSING HOMES

Jason Falvey,¹ Erinn Hade,² Steven Friedman,² Rebecca Deng,³ and Jasmine Travers,⁴ 1. *University of Maryland - Baltimore, Baltimore, Maryland, United States*, 2. *NYU Grossman School of Medicine, New York City, New York, United States*, 3. *NYU Wagner School of Public Health, New York City, New York, United States*, 4. *New York University, New York, New York, United States*

Severe socioeconomic disadvantage in neighborhoods where nursing homes (NH) are located may be an important contributor to disparities in resident quality of care. Disadvantaged neighborhoods may have undesirable attributes (e.g., poor public transit) that make it challenging to recruit and retain qualified staff. Lower NH staffing could subsequently leave residents vulnerable to adverse events. Thus, the purpose of this study was to evaluate whether NHs located in socioeconomically disadvantaged neighborhoods had lower healthcare provider staffing levels. We linked publicly available NH data geocoded at the Census block-group level with the Area Deprivation Index, a measure of neighborhood socioeconomic factors including poverty, employment, and housing quality (percentiles: 1-100). Consistent with prior literature on threshold effects of neighborhood poverty on outcomes, we characterized NHs as being located in a disadvantaged neighborhood if the census-block group

ADI score was $\geq 85/100$. We used generalized estimating equations clustered at the county level with fixed effects for state and rural location to evaluate relationships between ADI score and staffing. NHs located in socioeconomically disadvantaged neighborhoods had 12.1% lower levels of staffing for registered nurses (mean: 5.8 fewer hours/100 resident-days, 95% CI: 4.4-7.1 hours), 1.2% lower for certified nursing assistants (2.9 fewer hours/100 resident days; 95% CI 0.6-5.1 hours), 20% lower for physical therapists (1.4 fewer hours/100 resident-days; 95% CI 1.1-1.8 hours), and 19% lower for occupational therapists (1.3 fewer hours/100 resident-days; 95% CI 1.0-1.6 hours). These findings highlight disparities that could be targeted with policy interventions focused on recruiting and retaining staff in socioeconomically disadvantaged neighborhoods.

INFECTION CONTROL IN SMALL RESIDENTIAL CARE SETTINGS: INSIGHTS FROM A NATIONAL SURVEY AND WASHINGTON STATE DATA

Carolyn Ham,¹ and Anna Unutzer,² *1. Washington State Department of Health, Olympia, Washington, United States, 2. Washington State Department of Health, Shoreline, Washington, United States*

Infection control is a vital issue in long-term care, and the increasing popularity of small residential care facilities (SRCF) raises questions about the effectiveness of this model for preventing facility-acquired infections. In SRCF, care is provided in a residential home to a small number of residents. The setting lacks common terminology, and states license SRCF under various titles including Adult Family Homes, Adult Foster Homes and Family Care Homes. To better inform infection control efforts in this unique setting type, DOH staff conducted a comprehensive search to locate states that license SRCF. A total of 24 states were identified and approached to participate in a qualitative research study; 21 responded, three declined and nine were unable to participate due to staff time constraints. Between March 12th and April 15th, 2021, ten public health and regulatory staff from nine states completed semi-structured telephonic interviews on infection control in SRCF. Infection control licensing requirements and public health oversight for SRCF varied significantly across participating states. Data from these interviews was analyzed and compared with two Washington State Adult Family Home (AFH) sources: 1) online survey of AFH providers 2) Infection Control Assessment and Response evaluations conducted by public health staff. Four themes were identified in all three data sets: access to personal protective equipment, environmental safety, staffing issues and knowledge deficits. SRCF are valued by states that license them. Despite the challenges of implementing infection control in the home-like environment, extraordinary opportunities exist for improving care and preventing infections in this setting.

INFLUENCES OF PREJUDICE AND STEREOTYPING IN THE DIRECT CARE WORKFORCE

Jennifer May, *Duke University, Gaston, North Carolina, United States*

Direct Care Workers (DCW; nursing assistants, personal care aides, home health aides) have the most one on one care with sexual and gender minority (SGM) older adults

who reside in residential care facilities or use home health services. DCWs make up a vast majority of the healthcare workforce, holding almost five million jobs in 2019, with approximately 70% of the positions held being in residential care facilities. In a qualitative design study, 11 DCWs were interviewed using an open-ended, semi-structured format to describe their perceptions of care provided to SGM older adults in residential care facilities and the home health setting. These results were part of a larger qualitative study which found there were cues of stereotyping and prejudice in DCW narratives toward SGM older adults. The category DCWs' care and social system referred to characteristics of the DCWs' work environment and the perspectives, attitudes, and reported care toward SGM older adults and diverse populations. It was determined that there are synergies among SGM older adults' care and DCW along with DCW workforce issues (short staffed, low wages, lack of health benefits) that may prevent the DCW from being accepting of implicit bias training or culture change within these facilities/agencies. Implications for practice, policy, and future research are discussed.

INSIGHT INTO THE FEASIBILITY AND ACCEPTABILITY OF A MULTI-LIFESTYLE DEMENTIA RISK INTERVENTION

Laura Dodds, and Joyce Siette, *Macquarie University, Macquarie Park, New South Wales, Australia*

Lifestyle interventions based on behaviour change principles may provide a useful mechanism in reducing dementia risk amongst older adults, however intervention acceptability remains relatively unexplored. We assessed the feasibility and acceptability of BRAIN BOOTCAMP, an Australian initiative aiming to improve dementia literacy and reduce dementia risk by delivering a brain health box addressing multiple lifestyle factors through education, physical prompts and an individualised brain health profile. Semi-structured phone interviews were conducted with participants (N=94) at completion of the program (3-months) using a theoretical sampling approach to select a range of participants with varying brain health scores, age, gender, education and locality. Interview topics included participants' overall experience and suggestions for program improvement. Interviews were transcribed and analysed using thematic analysis. Participants were mostly female (79%), with a mean age of 72.6 years (SD=5.4), from an English-speaking background (89.4%) and resided in metropolitan areas (76.6%). Participants positively perceived the program, resulting in high usability and acceptability. Valuable aspects included building dementia awareness in an innovative way, and having re-assessments which identified areas for personal improvement. Participants further discussed how the program prompted lifestyle change, including setting goals (e.g., physical activity) and facilitated a general awareness of their brain health. Suggested improvements included shorter surveys, regular check-ins, and specific tailoring of the program to be more inclusive for older adults with varying levels of health. Our study demonstrated that a simple, innovative program could be a promising medium for delivering comprehensive educational resources and induce lifestyle change for older adults.

INTERDISCIPLINARY INNOVATIONS UTILIZING PET ROBOTS TO MEET RESEARCH, EDUCATION, AND CARE NEEDS

Meredith Troutman-Jordan,¹ and Boyd Davis,² 1. *University of North Carolina Charlotte, Charlotte, North Carolina, United States*, 2. *UNC Charlotte, Charleston SC, South Carolina, United States*

Studies of the impact of robotic companion pets are proliferating, authored by several disciplines, each with different concerns. Robotists focus on technology design and artificial emotional intelligence as opposed to general preferences for soft, furry, interactive animals. Others worry that as people interact with potentially deceptive technology, they may think the pet is alive. While aware of these serious concerns, gerontologists have focused on how lonely older persons without cognitive impairment respond to social 'helper' robots. More recent studies emphasize the possible impact of animatronic pets on persons with dementia (PWD). Therapeutic benefits of these pets are just being established. Our current pilot study is timely in that it now involves semi-structured interviews with formal/ informal caregivers of PWD who have been given a robot pet. We are eliciting perceptions, opinions, and observations of the PWD's response to robotic pets. We recruited 8 gerontology students as much-needed assistants for a research-driven topics course to afford them field exposure to PWD, caregivers, and direct research experience. Because students seldom have experience either with robotic pets or PWD, they read selected articles and received training/practice in semi-structured interviewing techniques. Students next conducted interviews with caregivers of PWD who have interacted with the pets. All interviews are audio-recorded, transcribed and deposited in the Carolinas Conversations Collection. Content and thematic analysis of transcriptions, student activity logs and bi-weekly reflective discussions will inform next steps in intervention research, testing therapeutic outcomes such as agitation reduction by pet robots for PWD.

LOW COGNITIVE PERFORMANCE INCREASES THE RISK OF HOSPITAL-ASSOCIATED COMPLICATIONS IN OLDER ADULTS

Juliana Souza-Talarico,¹ Siomara Yamaguti,² Adriana Dutra,³ and Daniel Apolinario,³ 1. *The University of Iowa, Iowa City, Iowa, United States*, 2. *Hospital do Coracao HCor, Hospital do Coracao (HCor), Sao Paulo, Brazil*, 3. *Hospital do Coracao HCor, Hospital do Coracao HCor, Sao Paulo, Brazil*

Considering the limited evidence regarding the factors that contribute to long-term consequences after hospitalization of older people, we analysed the relationship between cognitive performance and hospital-associated complications (HAC). One thousand, three hundred Individuals aged 60 and older (mean age 82.3, 53.3% female), not assigned to palliative care and admitted in medical and surgical wards from a private hospital, were followed up from admission to 30 days after discharge. HAS was evaluated using a multicomponent measure that combines 12 hospital-associated complications (delirium, functional decline, falls, pressure injuries, bronchoaspiration, non-planned ICU transfer, physical restraints, hospital stay > 30 days, death, long-term care transfer, and readmission). Cognitive performance was

assessed using the "10-point cognitive screener (10-CS)", which combines temporal orientation, category fluency, and word recall evaluation. Results: Overall, 464 (35.7%) participants had one or more HAC during their admission. Patients with HAC showed lower 10-CS scores than those with in HAC ($p < 0.001$). Adjusting for sociodemographic data, medication, chronic diseases, delirium screening, functional performance, each 10-CS point decreased the HAC changes by 19.2% (odds ratio = 0.808; 95% CI = 0.660 – 0.990). Conclusion: These findings show that low cognitive performance was significantly associated with the risk of developing HAC during hospitalization and within 30 days after discharge. That evidence forms the critical foundation for the next steps towards validating the accuracy of these models in predicting vulnerability to HAC and developing screening tools to be used at the point of care.

LUNG FUNCTION RESERVE AND PHYSICAL FUNCTION IN HEALTHY OLDER ADULTS: FINDINGS FROM BLSA

Joey Saavedra,¹ Ajoy Karikkineth,² Luigi Ferrucci,² and Eleanor Simonsick,³ 1. *Iowa State University, Ames, Iowa, United States*, 2. *National Institute on Aging, Baltimore, Maryland, United States*, 3. *National Institute on Aging/NIH, Baltimore, Maryland, United States*

Forced Expiratory Volume in 1-second (FEV1) that falls below the lower limit of normal (LLN) is a well-established correlate of functional limitation and disability. However, less is known about the functional implications of gradations of lung function above the LLN. We examined the cross-sectional association between gradations of healthy lung function and usual gait speed, reported walking ability, and fast 400m walk performance in 750 persons (50.7% men) aged 55-95 free from respiratory disease and mobility limitations, participating in the Baltimore Longitudinal Study of Aging (BLSA). The 2012 Global Lung Initiative (GLI) reference equations were used to calculate FEV1 Z-scores, with healthy lung function categorized as follows: $-1.6 < Z \leq -1.0$ (pre-clinical), $-1.0 < Z \leq -0.3$ (low normal), $-0.3 < Z \leq 0.3$ (normal), $0.3 < Z \leq 1.0$ (high-normal), and $Z > 1.0$ (high). Associations between gradations of healthy lung function and physical function were evaluated using multivariate linear regression, adjusting for age, sex, height, weight, and waist circumference. Compared to the 'pre-clinical' category, the difference in 400m walk time was 0.71 ($p > .05$), -6.60 ($p > .05$), -12.21 ($p < 0.05$), and -15.52 ($p < 0.01$) seconds for the 'low normal', 'normal', 'high-normal', and 'high' categories, respectively. No associations between gradations of healthy lung function and normal gait speed or walking ability were found ($p > 0.05$). Higher levels of lung function reserve are associated with better 400m walking performance, thus efforts to promote and/or reduce loss of lung function reserve may help individuals maintain high functional capacity in later life.

MAINTENANCE OF PHYSICAL FUNCTION IN ADULT AND OLDER ADULT MICE USING AEROBIC EXERCISE

Ted Graber, Megan Pajski, Christopher Byrd, Nainika Nadigama, Alyssa Fennel, Emily Seguin, and Anna Seguin, *East Carolina University, Greenville, North Carolina, United States*

As we age, physical and neuromuscular function declines gradually. Exercise is a therapy to improve neuromuscular ability. Pre-clinical models are needed to understand molecular mechanisms contributing to age-associated functional decline and how exercise affects that downward trajectory. Our goal was to compare the differences in effects of two validated mouse models of endurance exercise designed to mimic human training studies: high intensity interval training (HIIT) and voluntary wheel running (VWR). We hypothesized that both adult and older adults (10 and 26 months old at end, respectively: 10m and 26m) would respond to both exercise regimens by improving or maintaining exercise/physical capacity, but that adult mice would benefit more. We randomly assigned male C57BL/6 mice into experimental groups: 10m: (VWR, HIIT, sedentary control, CON, n=8 per group), and 26m (VWR, n=8, HIIT, n=10). We measured functional ability (pre- and post-intervention) using CFAB (comprehensive functional assessment battery), our composite scoring system (grip strength, inverted cling, treadmill endurance, activity rate, rotarod), tracked body composition (EchoMRI), and measured muscle wet mass. We found that significant retention of ability (CFAB difference, repeated measures ANOVA, $p < 0.05$) and fat percentage (ANOVA, %change: 10m: CON +125%, HIIT +101%, VWR +52%; 26m: VWR -42%, HIIT +26%, $p < 0.05$) was promoted by both exercise modalities compared to control, and furthermore HIIT may have better efficacy in the adult versus the older mice. In conclusion, both exercises are valid models with derived benefits as expected in similar human studies. We anticipate future work using these models to undertake mechanistic investigations.

MAPPING THE ENDOGENOUS KETOGENIC SYSTEM ACROSS AGES, SEX AND DIETS

Brenda Eap,¹ Mitsunori Nomura,¹ Oishika Panda,² Thelma Garcia,¹ and John Newman,³ 1. *Buck Institute for Research on Aging, Buck Institute for Research on Aging, California, United States*, 2. *Buck Institute for Research on Aging, Buck Institute of Research on Aging, California, United States*, 3. *Buck Institute for Research on Aging, Novato, California, United States*

Understanding how our cells maintain energy homeostasis has long been a focus of aging biology. A decline in energy metabolism is central to many age-related diseases such as Alzheimer's disease, heart failure, frailty, and delirium. Intervening on pathways involved in energy homeostasis can extend healthy lifespan. When our primary energy substrate glucose, is scarce, our bodies use ketone bodies (i.e. beta-hydroxybutyrate, acetoacetate, acetone). Aging is associated with glucose intolerance and insulin insensitivity, yet what role ketone body metabolism might play in compensating for impaired glucose utilization in age-related diseases is understudied. Here, we investigated how the body's endogenous ketone body production and utilization pathways are modulated by age across the lifespan of female and male C57BL/6 mice (4 mo old, 12 mo old, 22 mo old). We show how different ages have different metabolic and gene expression responses to 1-week ketogenic diet (KD) or ketone ester diet. We observed an apparently compensatory ketogenic response in older animals fed normal diet, with a stronger compensatory response driven by KD. We observed tissue-specific

changes, including induction of ketone body production enzymes in the aging heart. When comparing the ketogenic capacity between sexes, females had a higher basal level and less variation with age, underscoring the importance of sexual dimorphism in metabolism. Overall, these findings suggest that older animals use ketone bodies to meet energetic demands in a normal diet context. This study supports the potential roles of ketogenic therapies such as exogenous ketones to improve energy homeostasis in conditions of aging.

MENTORSHIP PROGRAM CONTENT RATINGS: ADVANCING DIVERSITY IN AGING AND ALZHEIMER'S DISEASE RESEARCH AND CAREERS

Sheri Thompson,¹ and Lauren Pineda,² 1. *University of California San Diego, encinitas, California, United States*, 2. *UCSD, UCSD, California, United States*

MADURA is an R25 Advancing Diversity in Aging Research (ADAR) undergraduate training program funded by the National Institute on Aging and based at the University of California San Diego. Its objectives are to improve retention and academic success of underrepresented minority (URM) trainees, and to increase graduate/medical school applications and/or entry into Aging/ADRD careers. This multi-component program includes paid research lab experience, research and academic skills training, peer support, faculty-led small groups, guest seminars, and additional professional development opportunities. The Year 1 Cohort of 32 students consisted of Hispanic/Latinx and other students under-represented in collegiate MSTEM studies. Almost $\frac{3}{4}$ of the mentees also came from disadvantaged backgrounds, per current NIH criteria. Evaluation data have been collected through brief, weekly, anonymous online student surveys, plus more comprehensive quarterly mentee and mentor surveys. This poster will describe the Program structure and 20+ group activities, trainings, seminars, and modalities, and report student ratings of satisfaction and utility. 92% of trainees rated the overall program value as Excellent, and 92% also rated effectiveness in promoting Aging/ADRD careers among underrepresented students as Excellent. Quality ratings of components such as pay, research placements, group training and group mentorship were rated as Excellent or Good by 96%. Relative student component rankings, specific suggestions for improvements, plus Mentee and Mentor perspectives on research-specific training needs, will also be presented. Based upon these experiences and data, the authors will make specific suggestions for future URM research training, mentorship program content, and expanded delivery modalities.

NEURON-SPECIFIC MECHANISMS CONTROL THE MITOCHONDRIAL REGULATOR PGC-1A

Eric McGregor,¹ Dylan Souder,¹ Josef Clark,² Timothy Rhoads,² Kevin Elicieri,² Mark Beasley,³ Darcie Moore,² and Rozalyn Anderson,⁴ 1. *University of Wisconsin--Madison, Madison, Wisconsin, United States*, 2. *University of Wisconsin-Madison, Madison, Wisconsin, United States*, 3. *University of Alabama at Birmingham, University of Alabama at Birmingham, Alabama, United States*, 4. *University of Wisconsin College of Medicine, University of Wisconsin, Madison, Wisconsin, United States*

Mitochondrial dysfunction has been proposed as a hallmark of the aging process. Specifically, as a function of aging,

mitochondria appear to have decreased enzyme activity and respiratory capacity and increase reactive oxygen species production. Brain aging is associated with morphological and homeostatic changes, including alterations in brain size, cognitive impairment, and white and grey matter integrity. However, the causes of these changes remain an open and actively pursued field of study. The ubiquitously expressed transcriptional coactivator peroxisome proliferator-activated receptor gamma-coactivator 1 (PGC-1a) has been described as the master regulator of mitochondrial function. Despite the emerging connections between PGC-1a and disease vulnerability, the regulation of PGC-1a outside of the skeletal muscle, liver, and adipose tissue is not well defined. This is particularly true in the brain, where PGC-1a is enriched in neurons, and alterations in expression levels have been linked to neurodegenerative disorders. Here we report that astrocytes and neurons differ substantially in mitochondrial status and the transcript variants of PGC-1a expressed, including using a neuron-specific promoter. Taking advantage of the ability of the tau-kinase GSK-3b to influence PGC-1a expression, we investigate how transcript variants are differentially regulated in primary neurons and astrocytes. Neuronal PGC-1a responds robustly to GSK3b inhibition by lithium, switching the dominant promoter, leading to changes in isoform distribution and abundance, while astrocytes are refractory to lithium treatment. The data presented here highlight key mechanisms for neuron-specific metabolic regulation that are likely to be relevant to neurodegenerative diseases that have a link to mitochondrial dysfunction.

NIA COORDINATED ANALYSIS OF DYNAMIC SOCIOEMOTIONAL EXPERIENCES AND WELL-BEING DURING THE PANDEMIC

Shevaun Neupert,¹ Sumbleen Ali,² Isabella Bouklas,³ Rita Hu,⁴ Reilly Kincaid,⁵ Niccole Nelson,⁶ Shiyang Zhang,⁷ and Stacey Scott,⁸ 1. *North Carolina State University, Raleigh, North Carolina, United States*, 2. *Stony Brook University, State University of New York, New York, United States*, 3. *Duke University, Durham, North Carolina, United States*, 4. *Social Work, Ann Arbor, Michigan, United States*, 5. *Purdue University, West Lafayette, Indiana, United States*, 6. *University of Notre Dame, University of Notre Dame, Indiana, United States*, 7. *The University of Texas at Austin, Austin, Texas, United States*, 8. *Stony Brook University, Stony Brook, New York, United States*

We conducted a coordinated analysis of eight longitudinal studies with data collected during the COVID-19 pandemic. Our overarching aim was to examine within-person fluctuations in health and well-being during the pandemic that may differ across the adult lifespan. The studies are from different regions of the U.S. with data collected during different periods of the pandemic. These studies sampled heterogeneous age groups, used diverse methods, and were harmonized on constructs. Four longitudinal studies (Notre Dame Study of Health & Well-being, Within-Family Differences Study, Social Relations Study, and the Einstein Aging Study [EAS] Covid Telephone Interviews) and four intensive, microlongitudinal studies (Daily Experience and Well-being Study, Daily COVID-19 Spring, Daily COVID-19 Fall, EAS), with data collected between March 2020 and August 2021 were analyzed. In three studies, older adults were consistently

less variable (i.e., lower within-person standard deviation) in negative emotional well-being such as negative affect and depressive symptoms compared to younger adults. In four studies older adults were also less variable in stress. Evidence of better outcomes associated with social interactions was found in three studies, where within-person variability in social interactions was positively correlated with variability in positive affect across age. These findings point toward the complexities of dynamic socioemotional experiences that unfold across historical periods and across the lifespan. These within-person fluctuations could be used as a benchmark to examine long-term trajectories of well-being.

NON-PHARMACOLOGICAL INTERVENTIONS TO MANAGE TYPE 2 DIABETES IN OLDER HISPANICS: A SYSTEMATIC REVIEW

Edgar Vieira,¹ Kayleigh Sherbutt,¹ Madison Scanlan,² and Heather Frederick,¹ 1. *Florida International University, Miami, Florida, United States*, 2. *Florida International University, Miami, Florida, United States*

Type 2 diabetes is a serious public health problem that affects millions of Americans. Hispanics are disproportionately affected and have high incidence of type 2 diabetes. Lifestyle modifications in diet and increased physical activity are recommended in addition to medication. The purpose of this systematic review was to analyze the scientific literature concerning the effects of exercise, nutrition, and combined diet and exercise interventions on type 2 diabetes management in older Hispanics. We searched three databases for studies that included dietary interventions, exercise interventions, or a combination to manage type 2 diabetes in older Hispanics. A total of 653 studies were screened and reviewed, with seven being included in the review. Our findings indicate that physical activity interventions significantly reduce glycosylated hemoglobin, and diet interventions also led to decreased levels of HbA1c. There is a significant effect in HbA1c levels on individuals receiving a combination of diet and exercise interventions compared to control groups. Implementing diet or exercise interventions in older Hispanics with Type 2 diabetes leads to significantly reduced glycosylated hemoglobin levels; the effects of combined diet and exercise interventions were not superior to the effects of single interventions in HbA1c levels. Exercise and diet seem to be effective non-pharmacological interventions to manage type 2 diabetes in older Hispanics, but additional research is needed.

NORMALIZED GRIP STRENGTH IS INVERSELY ASSOCIATED WITH DNAM AGE IN MIDDLE AGE AND OLDER ADULTS.

Mark Peterson,¹ Stacey Collins,² Helen Meier,² and Jessica Faul,¹ 1. *University of Michigan, University of Michigan, Michigan, United States*, 2. *University of Michigan, Ann Arbor, Michigan, United States*

There is a large body of evidence linking muscular weakness, as determined by low grip strength, to a host of negative aging-related health outcomes. Given these links, grip strength has been labeled a “biomarker of aging”; and yet, this metric provides no biological plausibility. The objective of this study was to determine the association between grip strength and DNA methylation (DNAm) age acceleration. Middle age and older adults from the

2006-2008 waves of the Health and Retirement Study with 8-years of follow-up were included. Cross sectional and longitudinal modeling were performed to examine the association between grip strength (normalized to body mass: NGS) and DNAm age acceleration, adjusting for cell composition, sociodemographic variables, and smoking. Three DNAm clocks were incorporated for estimating age acceleration including the established DunedinPoAm, Levine, and GrimAge clocks. There was a robust and independent cross sectional association between NGS and DNAm age for men (β :-0.36; p <0.001) and women (β :-0.36; p <0.001) using the DunedinPoAm clock, and for men only using the Levine (β :-8.04; p =0.01) and GrimAge (β :-4.76; p =0.01) clocks. There was also an independent longitudinal association between baseline NGS and DNAm age for men (β :-0.27; p <0.001) and women (β :-0.36; p <0.001) using the DunedinPoAm clock, and for women only using the Levine (β :-8.20; p <0.001) and GrimAge (β :-6.04; p <0.001) clocks. Our findings provide some evidence of age acceleration among men and women with lower NGS. Future research is needed to understand the extent to which DNAm age mediates the association between grip strength and chronic disease, disability, and mortality.

OLDER PEOPLE'S PERCEPTIONS OF WHAT IS NEEDED TO EXPERIENCE DIGNITY AND WELL-BEING AT RESIDENTIAL CARE FACILITIES.

Charlotte Roos,¹ Anna Swall,¹ Lena Hammar,² Anne-Marie Boström,³ and Bernice Skytt,⁴ 1. *Dalarna University, Falun, Dalarnas Lan, Sweden*, 2. *Mälardalen University / Dalarna University, Västerås, Västmanlands Lan, Sweden*, 3. *Karolinska Institutet, Karolinska Institute, Stockholms Lan, Sweden*, 4. *University of Gävle, Gävle, Gavleborgs Lan, Sweden*

Dignity and well-being are central values in care of older people living in residential care facilities. In addition, care of older people living in residential care facilities should be person-centred. Dignity and well-being can according to the person-centred practice framework be interpreted as person-centred outcomes. Despite this older people living in residential care facilities have described that they not fully experience dignity and well-being and improvements are needed. To improve care it is important to know what to target. The aim of this qualitative study was therefore to describe residents' perceptions and experiences of what is needed to live with dignity and a sense of well-being. Interviews were carried out with older people living at residential care facilities ($n=20$). Inductive content analysis was used to analyse data and one overarching theme and three categories emerged. The result revealed the importance of, and that staff and the care environment supported, to manage daily life by oneself, to be shown respect and to belong to a social context. For older people to experience the person-centred outcomes dignity and well-being managers at residential care facilities need to develop and support the staff prerequisites related to knowledge, skills and attitudes and to improve the care environment. According to the person-centred practice framework, the staff prerequisites and the care environment must be taken into account to achieve the person-centred outcomes dignity and well-being.

PEAK EXPIRATORY FLOW PREDICTS INCIDENT DEMENTIA IN A U.S. SAMPLE OF OLDER ADULTS

Patrick Donahue,¹ Qian-Li Xue,² and Michelle Carlson,³ 1. *Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*, 2. *Johns Hopkins University School of Medicine, Baltimore, Maryland, United States*, 3. *Johns Hopkins University, Baltimore, Maryland, United States*

Dementia is an increasingly important public health problem with known vascular contributors. Respiratory function, measured by peak expiratory flow (PEF), may be a novel modifiable risk factor in reducing the risk of dementia along the vascular pathway. We investigated the association between PEF and incident dementia in older adults from the National Health and Aging Trends Study (NHATS). Using NHATS criteria, participants were categorized as having or not having probable incident dementia during NHATS Rounds 2-4, spanning three years. Of 3,622 participants with available PEF and covariate data, 543 (15.0%) had incident cases of dementia. Quartile of baseline PEF was analyzed as a predictor of incident dementia using logistic regression models, while controlling for several health and sociodemographic covariates. The fourth quartile of PEF had statistically significantly decreased odds of incident dementia when compared to the first PEF quartile (OR = 0.27; 95% CI [0.19, 0.40]). Significantly reduced odds of incident dementia were found when comparing the third and second PEF quartiles to the first PEF quartile, as well (OR = 0.35; 95% CI [0.26, 0.47] and OR = 0.62; 95% CI [0.48, 0.80], respectively). These relationships were dose-dependent so that increasing PEF quartile levels were more protective against incident dementia. PEF may be considered as an easily administered, low-cost measure of respiratory function and a possible screening tool for dementia risk. Improving PEF may reduce dementia risk through vascular mechanisms (e.g., increased blood circulation and brain oxygenation). Future research should explore these potential causal pathways between PEF and dementia.

PERCEIVED PARTNER RESPONSIVENESS AND DEPRESSION: THE MODERATING ROLE OF AGE AND GENDER

Betul Urganici, *Cornell University, Ithaca, New York, United States*

A growing body of research suggests that greater perceived partner responsiveness- the extent to which individuals feel cared for, understood, and validated by their romantic partner- leads to longer, healthier, and happier life in adulthood, yet little is known about possible moderating factors between responsiveness and well-being. Using a longitudinal design, the current study tested the moderating roles of age and gender in association between perceived partner responsiveness and depression symptoms. The data for the present study came from the National Survey of Midlife in the United States (MIDUS I and II) which is a longitudinal study on health and aging. A life span sample of 2856 married or cohabiting individuals (1402 Female, Mage= 47.16) completed measures of perceived partner responsiveness, depression, age, and gender in two waves (T1 and T2). The results showed that greater perceived partner responsiveness

at T1 predicted lower depressive symptoms at T2 controlling for depressive symptoms at T1. This finding remained when controlling for potential confounders including demographics and health covariates. The moderation analysis demonstrated that participants' age was not a significant moderator in the association between perceived partner responsiveness and depression. Yet, gender significantly was a significant moderator such that the association of perceived partner responsiveness and depression was significant for female but not for male participants. These findings can have implications for mental health and relational well-being.

PILOT TESTING OF THE UB-CAM DELIRIUM SCREENING APP

Ashley Kuzmik,¹ John Joseph Hannan,² Long Ngo,³ Marie Boltz,⁴ Priyanka Shrestha,⁵ Sharon Inouye,⁶ Donna Fick,⁴ and Edward Marcantonio,⁷ 1. *Penn State University, University Park, Pennsylvania, United States*, 2. *Pennsylvania State University, State College, Pennsylvania, United States*, 3. *Harvard T.H. Chan School of Public Health, Brookline, Massachusetts, United States*, 4. *Pennsylvania State University, University Park, Pennsylvania, United States*, 5. *Betty Irene Moore School of Nursing (UC-DAVIS Health)*, 6. *Harvard Medical School, Boston, Massachusetts, United States*, 7. *Beth Israel Deaconess Medical Center, Boston, Massachusetts, United States*

Systematic screening improves delirium detection among hospitalized older adults. This poster describes the development and pilot testing of an iOS-based app that incorporates the Ultra-Brief Confusion Assessment Method (UB-CAM), a two-step, delirium detection protocol that combines the UB-2 (2-item screener) and 3D-CAM. Previous work tested a RedCAP-based UB-CAM app in 527 patients with 399 physicians, nurses, and certified nursing assistants (CNAs) showing it can be successfully completed by all three disciplines in 97% of eligible patients in 80 seconds on average with over 85% accuracy relative to a gold standard. To improve accessibility to the clinical setting, our research team now collaborated with a computer scientist to develop and refine an iOS-based UB-CAM app for the iPhone and iPad through iterative "laboratory" testing. The app was piloted by non-clinician, research testers in hospitalized older adults (age \bar{x} = 83, SD = 8.0) with dementia (Clinical Dementia Rating Scale \bar{x} = 1.1, SD = .30); 64% were assessed to be delirium positive. The app demonstrated preliminary efficiency (90 seconds on average), high acceptability (100% satisfaction of users), and reliability (100% inter-rater). This project underscores the need for close collaboration between researchers, clinicians, and computer scientists with iterative testing of bedside-facing apps prior to testing with patients. Next steps include testing effectiveness in a pragmatic trial with clinician users (physicians, nurses, CNAs), integrating the UB-CAM app into the routine hospital care of all older patients. Having rapid, accurate bedside delirium detection has the potential to transform care.

PILOTING THE "ANTI-OPPRESSIVE PRACTICE & RESEARCH WITH DIVERSE OLDER ADULTS" TRAINING PROGRAM DURING COVID-19

David Camacho,¹ Kelly Pacheco,² Sabrina Feldman,² Usha Kaul,² Patricia Kim,³ and M. Carrington Reid,⁴

1. *University of Maryland Baltimore, Baltimore, Maryland, United States*, 2. *New York University, New York University, New York, United States*, 3. *Weill Cornell Medicine, Weill Cornell Medicine, New York, United States*, 4. *Weill Cornell Medical College, New York, New York, United States*

There is a critical need to develop our gerontological-sensitive workforce. Social workers (SW) frequently provide services to older adults yet there are few opportunities for them to train as gerontological clinicians and/or researchers. To provide an opportunity for SW students to gain gerontological knowledge, clinical practice, and research skills, we developed, and pilot tested the "Anti-Oppressive Practice and Research with Diverse Older Adults" virtual training program at a major medical facility in Manhattan, NY. We explored the feasibility, implementation, and impact of this novel program. The 21-hour weekly MSW field placement program followed an anti-oppressive framework and included: 1) supervision and training sessions; and 2) direct clinical and research practice (e.g., theory, funding, assessment, data collection etc.) and aging topical seminars (e.g., depression, loneliness, pain etc.). Racially diverse supervisors and graduate SW students engaged in reflective writing exercises, iterative discussions (recorded & transcribed) and a thematic analysis of data. All interns successfully completed the program and reported enhanced skills related to SW core competencies and research (e.g., standardized assessments), research and practice gap awareness (e.g., minority aging) and plans to pursue advanced research training and/or gerontological clinical work. Intern challenges included: 1) disconnect between MSW curricula and research placements; and 2) managing minority and contextual stressors (e.g., imposter syndrome, covid-19, civil unrest). Supervisory challenges included: 1) humanizing sensitive discussions via virtual communication and 2) resource constraints. Future research should systematically assess program effects (e.g., SW core competencies) and how to facilitate interprofessional collaborations to develop diverse gerontological SWs and researchers.

PLEASE DO SOMETHING: WHAT CAREGIVERS FOR FAMILY MEMBERS WITH FTD NEED

Samantha Smith,¹ Leslie Tran,¹ and Allison Lindauer,² 1. *Oregon Health & Science University, Portland, Oregon, United States*, 2. *Oregon Health Sciences University, Portland, Oregon, United States*

Frontotemporal dementia (FTD) often presents with pronounced behavioral symptoms that contribute to family Care Partner (CP) burden and psychological strain. FTD-specific interventions that support the unique challenges of FTD-CPs are lacking. The present focus group study (Phase 1), elicited feedback from twelve CPs of persons with FTD on the multi-component video-based STELLA intervention (Support via TEchnology: Living and Learning with Advancing ADRDs), to inform the revision and adaptation of STELLA for FTD-CPs (Phase 2). Using Thomas's (2006) analytic approach to evaluation data, the investigators reviewed the raw text from two focus groups and used an inductive approach to create categories that informed future STELLA adaptation and revision. To address trustworthiness, each investigator independently analyzed the transcripts and CP-annotated

STELLA booklets. Six commonalities emerged. Three address the caregiver experience: Burden and living with complex behaviors; Difficulties in getting a diagnosis; and Barriers to participation. The other three reflect specific intervention adaptations: Make a Roadmap, STELLA-FTD Structure, and Booklet edits. The focus group findings offer practical suggestions to create a revised STELLA intervention to address the needs of families living with FTD. The suggestions are nested in the intense caregiving experience of living with complex behavioral symptoms, feeling burdened, isolated, and “living in darkness.” Both the investigators and caregivers appreciate the difficulty in crafting an intervention that meets the needs of all families living with FTD, but the caregivers encouraged the team to develop “something”: “...You won't be able to solve every problem or meet every need... [but] please, please do something.”

PLEIOTROPY OF ALZHEIMER'S DISEASE AND EDUCATIONAL ATTAINMENT: INSIGHTS FROM THE SUMMARY STATISTICS

Yury Loika,¹ Elena Loiko,¹ Irina Culminkaya,¹ and Alexander Kulminski,² 1. *Duke University, Durham, North Carolina, United States*, 2. *DUKE UNIVERSITY, Durham, North Carolina, United States*

Epidemiological studies report beneficial associations of higher educational attainment (EDU) with Alzheimer's disease (AD). Prior genome-wide association studies (GWAS) also reported variants associated with AD and EDU separately. The analysis of pleiotropic predisposition to these phenotypes may shed light on EDU-related protection against AD. We examined pleiotropic predisposition to AD and EDU using Fisher's method and omnibus test applied to summary statistics for single nucleotide polymorphisms (SNPs) associated with AD and EDU in large-scale univariate GWAS at suggestive-effect (5×10^{-8})

PREDICTIVE ABILITY OF SELF COMPASSION IN PSYCHOSOCIAL OUTCOMES OF CAREGIVERS OF PERSONS WITH DEMENTIA

Claire Grant,¹ and Katherine Judge,² 1. *Cleveland State University, South Euclid, Ohio, United States*, 2. *Cleveland State University, Cleveland, Ohio, United States*

Caregivers of Individuals with Dementia (IWDs) often face increased rates of depression, anxiety, and burden because of their role as caregiver. Self-compassion, a construct centered around self-kindness and understanding has not been well studied within the caregiving population. The present study was aimed at understanding the relationship between self-compassion and the psychosocial outcomes of burden, depression, and anxiety. Strong relationships between self-compassion and these outcomes have been established in other populations, but these relationships have not been studied with the dementia caregiving population. A diverse sample of dementia caregivers providing over 5 hours of care per week were recruited through CloudResearch and MTurk ($N = 99$). Participants were aged 18 to 69 years ($M = 38.61$) and 66.7% were female. 67.7% were White, 13.1% were Black, and 8.1% were Asian. 73% were children/in law or grandchildren/in law of the individual with dementia and 12% were a close friend of the individuals with dementia. The individuals with dementia had an average age

of 73.88 years. Results of multiple regression models showed that self-compassion was a significant predictor of depression ($\beta = -.25$, $p = .025$), anxiety ($\beta = -.36$, $p = .001$), and burden ($\beta = -.25$, $p = .023$) even while controlling for other constructs including self-esteem, types of coping, and IWD impairment level. Self-compassion will be discussed as a novel contribution to the caregiving literature in furthering our understanding of well-being predictors and how to target self-compassion as a modifiable factor for offsetting the negative impacts of caregiving.

PREDICTORS OF SLEEP AMONG SPOUSAL CARE DYADS LIVING WITH CHRONIC CONDITIONS

Florence Johnson,¹ Sheria Robinson-Lane,² Lianlian Lei,³ Yin Liu,⁴ Yeonsu Song,⁵ Seung-won Emily Choi,⁶ and Toni Antonucci,³ 1. *University Of Michigan School of Nursing, Ann Arbor, Michigan, United States*, 2. *University of Michigan School of Nursing, Ann Arbor, Michigan, United States*, 3. *University of Michigan, Ann Arbor, Michigan, United States*, 4. *Utah State University, Logan, Utah, United States*, 5. *UCLA, Los Angeles, California, United States*, 6. *Texas Tech University, Lubbock, Texas, United States*

Sleep health relates closely to physical health and well-being among older adults with chronic health conditions. However, little is known about the dyadic sleep patterns of these individuals and their spousal caregivers. Secondary analyses of the 2015 National Health and Aging Trends Study and National Study of Caregiving ($N = 62$ care dyads, mean age 78.59 years for care recipients and 75.77 years for caregivers) were completed to examine the sleep patterns, and related factors, of spousal dyads at both the individual and dyadic levels. Sleep measures included frequency in trouble falling back asleep and insomnia symptoms. Predictors included demographics, depressive symptoms, and positive affect for dyads and contextual factors such as dementia caregiving, care burden and support, neighborhood cohesion, and relationship quality. Multilevel dyadic and actor-partner interdependence models were used to complete analyses. Though intraclass correlation was poor (dementia care dyads $ICC = 0.123$, non-dementia care dyads $ICC = 0.043$), persons with dementia/spousal caregiver dyads ($n = 102$) had more similar sleep and insomnia patterns than dyads with other chronic conditions. Poor sleep among dyads was correlated with higher care burden ($\beta = -0.31$, $p < .0001$), however, better relationship quality marginally enhanced the association ($\beta = -0.23$, $p = .08$). Individual depressive symptoms negatively affected dyadic sleep patterns. However, positive affect only had an actor effect and was related to better individual sleep. Other contextual factors did not affect sleep patterns. These findings suggest the importance of both caregiver and care recipient characteristics on sleep at dyadic levels, particularly those with dementia.

PREFRONTAL ACTIVATION IS ASSOCIATED WITH GAIT QUALITY DURING AN ATTENTIONAL TASK IN OLDER ADULTS

Emma Baillargeon,¹ Anisha Suri,¹ Nemin Chen,¹ Xiaonan Zhu,¹ Caterina Rosano,¹ Ervin Sejdic,² Theodore Huppert,¹ and Andrea Rosso,¹ 1. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*,

2. Swanson School of Engineering, University of Pittsburgh, Pittsburgh, Pennsylvania, United States

Prefrontal cortical activation varies by walking task and is a marker of attentional demand. We compared prefrontal activation by functional near-infrared spectroscopy (fNIRS) to accelerometry-derived gait quality. We hypothesized greater activation with lower gait quality (greater step-time coefficient-of-variation, decreased cadence, smoothness, regularity, and signal variability). Participants ($n=114$; age 74.4 ± 6.0 years, 59.6% female) were independently ambulating individuals >64 years. Attentional (reciting every-other alphabet letter) and physical (uneven surface) challenges mimicked community mobility and provided four 15m walking conditions: even, uneven, ABC-even, and ABC-uneven. fNIRS data were referenced to quiet standing and averaged within left and right hemispheres. Gait metrics from a tri-axial accelerometer at the lower-back included cadence (steps/min), step-time coefficient-of-variation, signal variability (standard deviation), smoothness (harmonic ratio), and regularity (entropy). Associations between fNIRS and gait were quantified using Pearson correlations ($\alpha=0.05$). Results were consistent across hemispheres, gait axes, and robust to adjustment for age and gait speed; we report unadjusted coefficients for left hemisphere and anterior-posterior gait direction. Greater prefrontal activation was associated with slower cadence ($r=-0.220$, $p=0.019$), lower signal variability ($r=-0.228$, $p=0.015$), and reduced smoothness ($r=-0.194$, $p=0.039$) during ABC-even. No relation was observed for step-time coefficient-of-variation or regularity. Results were similar for the ABC-uneven condition, except there was no association with gait smoothness but was with step-time coefficient-of-variation ($r=0.25$, $p=0.007$). Prefrontal activation was not correlated to gait quality in non-ABC conditions. Our findings support our hypothesis only during the ABC challenge, suggesting that older adults may rely on prefrontal activation to complete attentional but not physical challenges during gait.

PREVENTING ELDER MALTREATMENT: IDENTIFICATION OF HIGH RISK FACTORS FROM LTC ADMINISTRATIVE DATA

Shiau-Fang Chao,¹ Chen-Wei Hsiang,² Kuan-Ming Chen,³ Ya-Mei Chen,⁴ Ji-Lung Hsieh,⁴ Yu-Hsuan Chou,⁴ Ming-Jen Lin,⁴ and Shih-Cyuan Wu,⁴ 1. *National Taiwan University, Taipei City, Taiwan (Republic of China)*, 2. *National Taiwan University, National Taiwan University, Taipei, Taiwan (Republic of China)*, 3. *National Bureau of Economic Research, CAMBRIDGE, Massachusetts, United States*, 4. *National Taiwan University, Taipei, Taipei, Taiwan (Republic of China)*

Elder maltreatment is a serious problem endangering physical, emotional, and material well-being of older persons, especially those with physical and cognitive impairment. However, detecting the incident of elder maltreatment is difficult and its prevalence has been seriously underestimated. This study explores how LTC use relates to elder maltreatment report, using government LTC service records in Taiwan. A total of 88,633 reported cases in adult protection system in 2019 were merged with 443,952 valid cases in LTC service system. Descriptive statistics were firstly performed to

examine the proportion and characteristics of repeated cases in both systems. Linear probability modeling was then used for analyses. 1. In 2019, 3,413 elder maltreatment clients can be identified in LTC service system, accounting for 27.3% of the elder maltreatment cases. 2. Older persons who used LTC service first and being reported as elder maltreatment cases later had a higher prevalence of being discovered by social workers and care attendants. 3. These group of clients also had higher proportion of being reported as neglected by others, abandonment, and self-neglected. 4. Characteristics in LTC service system, such as being older, low severity of disability, high cognitive impairments, low income status, and with a LTC service use record, were related to high probability of being detected with elder maltreatment problems. Characteristics in LTC service system could be effective indicators in discovering potentially abusive situations of disabled older persons. Training and education are essential for LTC service providers to enhance their literacy and ability of assessing elder maltreatment.

PSYCHOACTIVE SUBSTANCE USE AMONG MIDDLE-AGED AND OLDER ADULTS WITH VISUAL IMPAIRMENT

Francisco Lopez,¹ Jason Leddy,² Benjamin Han,² and Joseph Palamar,³ 1. *UCSD MADURA R25 Advancing Diversity in Aging Research Program, San Diego, California, United States*, 2. *UC San Diego, La Jolla, California, United States*, 3. *New York University, New York, New York, United States*

Older adults with visual impairment may be at risk for developing substance use disorder (SUD) as psychoactive substance use is often used to cope with the stressors of vision loss. This study estimates the national prevalence and risk of psychoactive substance use among older adults with visual impairment. We analyzed data of respondents age ≥ 50 from the 2015-2019 National Survey on Drug Use and Health, an annual cross-sectional survey of a nationally representative sample of non-institutionalized individuals in the U.S. ($N=43,886$). We estimated and compared prevalence of past-year use of cannabis, cocaine, misuse of prescription opioids, sedatives, stimulants/tranquilizers, alcohol use disorder (AUD), any SUD, and nicotine dependence between adults with visual impairment to those without. Comparisons were conducted using chi-square and we used multivariable generalized linear models using Poisson and log link to estimate adjusted prevalence ratios (aPRs) for adults with visual impairment relative to those without, controlling for demographics and diagnosis of ≥ 2 chronic diseases. An estimated 6.1% experienced visual impairment. Those with visual impairment had higher prevalence of AUD, nicotine dependence, misuse of prescription opioids, tranquilizers, and stimulants, and SUDs. In adjusted analyses, vision-impaired adults had higher risk of AUD (aPR=1.71, 95% CI: 1.40-2.09), nicotine dependence (aPR =1.53, 95% CI:1.35-1.73), opioid misuse (aPR =1.54, 95% CI:1.26-1.90), and SUD (aPR=1.67, 95% CI:1.40-2.01). Psychoactive substance use adds unique health risks for older adults with vision loss, who may suffer significant psychological stress and loss of independence. Screening for substance use among all older adults with visual impairment should be considered.

PSYCHOLOGICAL EFFECT OF ANTI-ASIAN ATTITUDES BY COVID-19 ON ASIAN AMERICANS IN COASTAL ALABAMA

Hosik Min,¹ Roma Hanks,¹ and Denise Lewis,² 1. *University of South Alabama, Mobile, Alabama, United States*, 2. *University of Georgia, Athens, Georgia, United States*

This study aimed to understand how the anti-Asian attitude due to the COVID-19 affected Asian American communities in Alabama. We asked whether Asian Americans were worried about going out due to the anti-Asian attitude due to COVID-19. This study conducted online surveys to Cambodians or Laotians, who were 18 years and older, were living in Coastal Alabama, in May 2020. To avoid in-person contact, respondents answered questions online. A total of 353 respondents participated in the survey. In the Cambodian community, more younger adults participated in the survey, while more middle-aged adults participated from the Laotian community. Laotians had longer educational attainment and watched multiple media to obtain COVID-19 related information. Cambodians (72%) were afraid of COVID-19 infection more than Laotians (53%). More Cambodians (73%) were afraid to go out because of the anti-Asian attitude than Laotians (52%). The logistic regression analysis presented that people worried more about the COVID-19 infection were less likely to go out due to anti-Asian attitudes. Educational attainment did not have a protective effect. Watching multiple media sources decreased the worry about the anti-Asian attitude for Laotians. The age cohort showed both a protective and exacerbate the effect. Cambodians, who were in their thirties, were worried about going out. However, Laotian fifties and over did not worry about going out. This difference might be related to the length of the stay in the U.S. Hanks et al. found that Cambodians, compared to Laotians, had more new immigrants who recently came to the community to marry.

PSYCHOSOCIAL MENTORSHIP NEEDS: PROMOTING DIVERSITY IN AGING AND ALZHEIMER'S DISEASE RESEARCH AND CLINICAL CAREERS

Sheri Thompson,¹ Lauren Pineda,² Savannah Gamboa,³ and Gisselle Santiago,³ 1. *University of California San Diego, encinitas, California, United States*, 2. *UCSD, UCSD, California, United States*, 3. *University of California San Diego, La Jolla, California, United States*

The UC San Diego MADURA Mentorship Program, funded by an R25 National Institute on Aging grant, has goals to improve diversity in Aging and Alzheimer's Disease (ADRD) research and clinical practice. MADURA strives to improve retention and academic success of its URM trainees, and to increase graduate/medical school applications and/or entry into Aging/ADRD careers. Mentees receive paid research experience, skills training, peer support, seminars, and additional professional development opportunities. Given local demographics and Co-Investigator expertise, MADURA recruits primarily Hispanic/Latinx (H/L) students, and other URM students. Non-exclusive racial identifications of 32 Year 1 mentees were: 69% H/L, 9% Black/African American, 22% Asian and 31% other race. 72% met NIH criteria for Disadvantaged Backgrounds. As of June 2021, 100% of students completed surveys assessing Racial Microaggressions and Imposter Syndrome experiences, and

Professional Self-efficacy. This poster will define the concepts, discuss relevance for URM student success and retention, and present student data on each topic. As examples, 56% of trainees experienced overt discrimination and 72% reported having experienced microaggressions at least occasionally, as undergraduates. As related to Imposter Syndrome, 62% secretly worried that others would find out that they are not as bright and capable as others think. Half attributed accomplishments to being a "fluke," or due to reasons other than true merit. Still, in terms of Professional Self-efficacy, 62% of mentees thought it moderately or very likely that they would succeed as an Aging/ADRD researcher. The authors will make specific suggestions for optimized URM training and mentorship program content, and provide resources.

RECRUITING RESIDENT PARTICIPANTS FROM NURSING HOMES DURING THE COVID PANDEMIC: CHALLENGES AND SOLUTIONS

Leena Almasri,¹ Barbara Carlson,¹ Julie Myers,¹ Rebecca Koszalinski,¹ Melissa Franklin,¹ Alysa Kelsh,¹ and Diana Sturdevant,² 1. *University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, United States*, 2. *University of Oklahoma HSC, Oklahoma City, Oklahoma, United States*

Recruiting nursing home residents as participants in research is challenging. In early 2021, Covid-19 cases rose rapidly in nursing homes, prompting the rapid deployment of infectious disease protocols and ultimately, facility lockdowns to control the spread of the virus. By September, 2020, many research projects were delayed or cancelled, and future research was jeopardized. During this period, as well as prior to and after the administration of the COVID vaccine, we enrolled residents in a complex protocol involving administration of two Shingles vaccines (0- and 90 days) and three separate blood samples. Here, we present the strategies we used to recruit 216 residents, from 23 homes, over a 9-month period. We faced many challenges. Our research staff faced weekly COVID-19 antigen tests prior to entering the facility, adhering to strict protocols on travel, as well as packaging of materials that entered and left the facility. N95 masks and face shields further made it difficult to communicate with residents. For homes, COVID protocols required residents to be transported to specified areas to meet with research staff. Daily monitoring of COVID and Shingrix vaccine symptoms became part of daily care. To minimize resident harm and interruption of workflow in nursing homes, we utilized principles of stakeholder engagement, healthcare leadership, infectious disease/immunology, and staff (research and nursing homes) empowerment. In the face of crisis, like the COVID-19 pandemic, we have gained the trust and commitment of these facilities; thus, establishing a sustainable partnership that is prepared for what comes next.

REMOTE ASSESSMENT PREFERENCES OF NIA ALZHEIMER'S DISEASE RESEARCH CENTER PARTICIPANTS DURING COVID-19 PANDEMIC

Michael Nunnerley,¹ Nora Mattek,² Zachary Beattie,³ and Jeffrey Kaye,³ 1. *Oregon Health & Science University, Vancouver, Washington, United States*, 2. *Oregon Health and Science University, Portland, Oregon, United States*, 3. *Oregon Health & Science University, Portland, Oregon, United States*

Background: In a progressively technology-infused world, older adults are becoming accustomed to the digitization of research participation. During the COVID-19 pandemic, it became necessary to conduct remote study visits typically carried out over the telephone or using video calling programs (e.g. Zoom). **Methods:** The National Alzheimer's Coordinating Center developed a COVID-19 Technology Accessibility Survey to determine preferred types of study visits for study participants and to understand how this older population accesses the internet. **Results:** Seven Alzheimer Disease Research Centers collected 1282 survey responses (mean age: ± 71.8 years, mean education: 16.5 ± 2.5 years, race/ethnicity: 86% White/non-Hispanic). In respondents aged 65-80, internet access was endorsed by 73% regarding smartphones, 61% for laptops, and 46% for tablets. Interest in wearable devices was expressed by 21% of respondents and interest in smart homes by 6%. Study visit preference among this age group was 42% in favor of in-person, 25% via phone, and 33% via video. In respondents aged >80 internet access was endorsed by 47% regarding smartphones, 47% for laptops, and 34% for tablets. Interest in wearable devices was expressed by 9% of respondents and interest in smart homes by 3%. Study visit preference among this age group was 38% in favor of in-person, 34% via phone, and 28% via video. **Discussion:** In light of the COVID-19 pandemic, the survey suggests many study participants are interested in remote visits. Significant age group differences are present regarding internet access. Further studies are required to increase the understanding of the efficacy of this research visit format.

RESILIENCE IN RELATION TO MULTIMORBIDITY IN OLDER ADULTS: A SCOPING REVIEW

Hohyun Seong,¹ Heather Lashley,¹ Katherine Bowers,¹ and Kirsten Corazzini,² 1. *University of Maryland Baltimore, Baltimore, Maryland, United States*, 2. *University of Maryland School of Nursing, Baltimore, Maryland, United States*

Multimorbidity is widespread, costly, and associated with a range of deleterious symptoms, affecting 70-80 % of older adults. Resilience in late life has been the focus of considerable research to understand differences in vulnerabilities and recovery from stressors relevant to multimorbidity. Despite this, previous reviews have not focused on resilience in relation to multimorbidity in older adults; therefore, this study synthesized relevant literature. The study design was a scoping review following JBI methodology. Searched electronic databases included PubMed, Embase, CINAHL, and PsycINFO. Data were extracted by two independent reviewers and charted using Garrard's review matrix method. Gough's weight of evidence criteria were used to appraise quality. Of 468 retrieved studies, 14 met inclusion criteria, primarily from the US, UK, and Canada. Most resilience in multimorbidity frameworks operationalize resilience as dependent on the socio-environmental context of older adults. Resilience was commonly considered a dynamic process, but only one study was longitudinal. Measures were primarily psychological or psycho-social in nature and did not include biological or physical measures of resilience. Quality of life and quality of care were common outcomes; resilience significantly related to these outcomes. Findings indicate both

the important relationships of resilience with outcomes of multimorbidity, as well as multiple gaps in our current understanding of resilience in relation to multimorbidity. Results highlight the need for studies with diverse populations across diverse cultures, studies that incorporate multidimensional measures, with attention to physiological or physical properties of resilience, and longitudinal studies that capture the dynamic process of resilience in multimorbidity.

SAFETY AND EFFICACY OF REPEAT DOSES OF ALLOGENEIC MESENCHYMAL STEM CELLS IN PATIENTS WITH AGE RELATED FRAILITY

Russell Saltzman,¹ Ivonne Schulman,² Aisha Khan,² and Joshua Hare,² 1. *University of Miami (UM), Miller School of Medicine - Interdisciplinary Stem Cell Institute (ISCI), Miami, Florida, United States*, 2. *University of Miami (UM), Miami, Florida, United States*

Age-related frailty is a common geriatric condition characterized by a decline in physical and immunological capacity that is associated with depletion of endogenous stem cells and leads to increased vulnerability for adverse health outcomes. Allogeneic mesenchymal stem cells (allo-MSCs) exert immunomodulatory effects and promote tissue repair, which may be able to impede the negative effects of the aging process. The objective of this study was to explore the safety and efficacy of repeated infusions of allo-MSCs in subjects with aging-frailty. Mean age at time of first and second infusions was 75.5 and 77 years of age, respectively. In this open-label clinical trial, 24 participants received two intravenous infusions of allo-MSCs with an average interval of 17.6 months between doses. Safety endpoints included incidence of treatment-emergent serious adverse events (TE-SAEs) within 1-month post-infusion and increase in Panel Reactive Antibodies (PRAs) at 6-months post-infusion. Primary efficacy endpoint was change in 6-minute walk test (6MWT) distance at 6-months post-infusion. No TE-SAEs occurred within 1-month post-infusion. PRAs remained stable throughout the study, indicating no evidence of immune rejection. 6MWT increased by 42 meters after the first infusion ($P=0.018$). Eighteen months later elevation persisted ($P=0.026$), but did not increase further after the second infusion. In summary, repeated intravenous infusions of allo-MSCs were safe in participants with age-related frailty and showed remarkable improvement in physical performance. Given the excellent safety and efficacy profiles demonstrated in this study, larger clinical trials are warranted to further quantify the efficacy of repeated dosing of allo-MSCs in this multisystem disorder.

SOCIAL ISOLATION, CAREGIVING ALONE, AND CAREGIVING STRESS IN FAMILY CAREGIVERS OF OLDER ADULTS IN KOREA

Sol Baik,¹ and Jiweon Jun,² 1. *University of Maryland, Baltimore, Baltimore, Maryland, United States*, 2. *Seoul National University, Center for Transnational Migration and Social Inclusion, Seoul National University, Seoul-t'ukpyolsi, Republic of Korea*

The tendency of caregiving alone is increasing, and these solo caregivers often perceive caregiving responsibilities as a burden. Still, literature on positive aspects of caregiving shows that not all caregivers experience severe distress. Little

is known on which factors make a difference in experiencing caregiving distress among solo caregivers. We focused on the empirical findings on the negative impact of social isolation on caregiver's mental health, examining if and how the intersection of solo caregiving and social isolation is related to severe caregiving stress among caregivers of older adults in Korea. We analyzed 501 family caregivers of older adults in Korea using survey data from the Care Work and the Economy research project (2018). We conducted ordinal logistic regression analysis. The findings show that solo caregivers with a lack of social time fall under the most at-risk group of caregivers in terms of experiencing severe stress (OR=3.72, SE=0.93) whereas solo caregivers with enough social time did not show significantly higher stress compared to the reference group (OR=1.50, SE=0.43). Being socially isolated caregivers still had high levels of stress despite the division of care (OR=2.16, SE=0.55), implying the need to provide caregivers more time for social interaction with others. The current public long-term care insurance in Korea provides limited hours of in-home care aide services to enable aging in place of older adults. To reduce the social isolation of caregivers, it is necessary to extend the service hours and provide support, such as creating online caregiver networks.

SOCIOECONOMIC STATUS ACROSS THE LIFE COURSE AND SMOKING TRAJECTORIES OF OLDER ADULT SMOKERS IN THE U.S.

Jaqueline Avila,¹ Sangah Lee,² Ezinwa Osuoha,³ Dale Dagar Maglalang,² Alexander Sokolovsky,² and Jasjit Ahluwalia,² 1. *Brown University, Providence, Rhode Island, United States*, 2. *Brown University, Brown University, Rhode Island, United States*, 3. *Cornell University, Cornell University, New York, United States*

The objective of this study is to assess how SES over the life course impacts smoking cessation among older adult smokers in the U.S. 6,058 current smokers 50 years and older were identified from the 1998-2018 Waves of the Health and Retirement Study (HRS). The outcome of interest was smoking cessation. The main independent predictor was lifetime SES, categorized as low child and low adult SES (persistent low); low child, high adult SES; high child, low adult SES; and high child, high adult SES (persistent high). Multilevel mixed-effect logistic model was used to examine how lifetime SES predicts smoking cessation at age 65 and over time, adjusted by health and smoking covariates. The majority of older smokers had persistent high lifetime SES (60.3%), followed by high child/low adult SES (18.7%), persistent low SES (15.5%) and low child/high adult SES (5.6%). Compared to those with persistent high SES, those with persistent low SES were more likely to be Hispanic (25.9% vs. 3.0%, $p < 0.001$) or non-Hispanic Black (22.7% vs. 8.7%, $p < 0.001$), respectively. The adjusted results showed that at age 65, compared to those with persistent high SES, those with persistent low SES, low child/high adult SES, and low adult/high child SES were less likely to quit (OR: 0.42, 95%CI:0[.31-0.56]; OR:0.37, [0.24-0.55]; OR:0.53, [0.40-0.70], respectively). Similar results were observed over time for those with persistent low SES and low adult/high child SES. However, there was no significant difference for those with low child/high adult SES.

STAYING CONNECTED DURING THE COVID-19 PANDEMIC: EXPERIENCES OF OLDER PEOPLE IN MEXICO AND SCOTLAND

Nereide Curreri,¹ Verónica Montes de Oca,² Louise McCabe,³ Marissa Vivaldo,⁴ Alison Dawson,³ Miguel Rivera,² Maria Arroyo,⁵ and Elaine Douglas,³ 1. *Optentia Unit, North-West University, South Africa, Stirling, Scotland, United Kingdom*, 2. *National Autonomous University of Mexico (UNAM), National Autonomous University of Mexico (UNAM), Distrito Federal, Mexico*, 3. *University of Stirling, Stirling, Scotland, United Kingdom*, 4. *National Autonomous University of Mexico, Mexico City, Distrito Federal, Mexico*, 5. *Universidad Juarez del Estado de Durango, Universidad Juarez del Estado de Durango, Durango, Mexico*

During the pandemic older people saw transformations in their social connections due to lockdowns and other restrictions. Technology provided one mechanism for them to stay connected with others, but technology may not be accessible or desirable for everyone. Gender, socioeconomic status, ethnicity, age and other factors enhance or limit engagement with technology. This project explored experiences of older people in Mexico and Scotland during the pandemic and examined the potential of everyday technology to help maintain social connectedness. A mixed methods approach included secondary analysis of large-scale datasets alongside primary data. Online semi-structured interviews and focus groups were carried out with 36 older people in Mexico and 23 older people in Scotland. Sampling was purposeful creating a diverse sample across age, gender, ethnicity and socioeconomic status. The findings demonstrate that advantages and disadvantages accumulated in the life course determine how older people select, optimize and compensate for new ways of staying socially connected during the pandemic in both countries. The use of technologies among older people is further mediated by structural inequalities with differences found between Mexico and Scotland in specific patterns identified. Further, stereotypes about older age and technology use are obstacles to the use of technology, as they affect the perception of self-efficacy by older people. Despite the obstacles, this study has shown that older people have a broad range of resources that have enabled them to cope with the pandemic and utilise technology to maintain social connections. The project offers recommendations to support older people's human rights.

THE EXPERIENCES OF OLDER ADULTS WITH CANNABIS AND MENTAL HEALTH: A SCOPING REVIEW OF THE LITERATURE

Raza Mirza,¹ Amanda Bull,² Andrea Gardiola,³ Sabina Mirza,⁴ Mary Hynes,¹ and Jessica Hsieh,¹ 1. *University of Toronto, Toronto, Ontario, Canada*, 2. *University of Toronto, Whitby, Ontario, Canada*, 3. *Queen's University, Toronto, Ontario, Canada*, 4. *York University, Woodbridge, Ontario, Canada*

Following the 2018 federal legalization of cannabis in Canada, there was a drastic increase in older adults reporting marijuana use. Most cannabis research today focuses on children and young adults, however, it is important to acknowledge the potential harms in seniors as well. Aging and substance use presents unique considerations, such as

the interactions between cannabis and chronic conditions, multiple comorbidities, polypharmacy, and mental health. The goal of this scoping review was to analyze the literature that addresses mental health outcomes of seniors who use cannabis, in order to answer the main research question: What is the relationship between older adults' use of cannabis and mental health? Following Arksey and O'Malley's five-stage framework, 10 electronic databases were searched along with a hand search of references. The search revealed 7000+ peer-reviewed and grey literature sources. 233 full-text sources were assessed for eligibility, with a total of 25 articles included. Thematic content analysis produced four major themes which addressed: (1) Usage characteristics; (2) User characteristics; (3) Outcomes; and (4) Physical and mental health considerations. Findings from this scoping review are positioned in terms of their implications for research, practice, and policy. While more in-depth, qualitative methods are required to develop further research, several harm-reduction strategies may be immediately utilized by both users and healthcare practitioners. It is critical that older adults and their physicians are able to make cannabis-related decisions with evidence-informed guidance to prevent problematic cannabis use and ensure positive mental health outcomes.

THE INFLUENCE OF COGNITIVE FUNCTION ON ADHERENCE TO BREAST CANCER SCREENING AMONG OLDER AMERICAN WOMEN

Chien-Ching Li,¹ Fritzi Flores,¹ Alicia K. Matthews,² Bryan James,³ and Raj Shah,⁴ 1. *Rush University, Rush University, Illinois, United States*, 2. *University of Illinois at UIC, Chicago, Illinois, United States*, 3. *Rush University, Chicago, Illinois, United States*, 4. *Rush, Rush University Medical Center, Illinois, United States*

Cognitive decline and impairment among older adults have become an important public health issue. Previous research shows older women have a greater prevalence of Alzheimer's disease than Men. Among women, breast cancer is one of the most common types of cancer. Over half of breast cancer deaths occur in women aged 65 and older. Therefore, early detection of breast cancer through mammogram screening is important among older women. This study aimed to examine the influence of cognitive function on adherence to mammogram breast cancer screening among older American women aged 65 and older. Data from the Health and Retirement Study (2012-2016) was obtained and analyzed. The independent variable of the study was cognitive function (normal, not normal). Adherence to mammogram (low, moderate, high) was the dependent variable. Multinomial regression was performed to examine the association between cognitive function and adherence to mammogram after controlling for demographic covariates. In the study, 33.3% of respondents had impaired cognitive function and 21.7% showed low adherence to mammogram screening. Regression results found that older women with impaired cognitive function were more likely to be in low adherence group (OR=1.30, p=0.01) or moderate adherence group (OR=1.47, p<0.001) relatively to be in high adherence group compared to older women with normal cognitive function. The development and implementation of interventions are needed for reducing barriers to accessing cancer screening services in high-risk vulnerable

populations. This submission is considered late-breaking research because study findings were obtained from a recently completed student's master's project.

THE LINK BETWEEN ENVIRONMENT, AGE, AND HEALTH IN A LARGE COHORT OF COMPANION DOGS FROM THE DOG AGING PROJECT

Brianah McCoy,¹ Layla Brassington,¹ Greer Dolby,¹ Kelly Jin,² Devin Collins,³ Matthew Dunbar,⁴ and Noah Snyder-Mackler,¹ 1. *Arizona State University, Tempe, Arizona, United States*, 2. *Allen Institute for Brain Science, Allen Institute for Brain Science, Washington, United States*, 3. *University of Washington, University of Washington, Washington, United States*, 4. *University of Washington, UNiversity of Washington, Washington, United States*

Exposure to social environmental adversity strongly predicts health and survival in many species such as non-human primates, wild mammals, and humans. However, little is known about how the health and mortality effects of these social determinants vary across the lifespan. Using the companion dog, which serves as a powerful comparative model for human health and aging due to our shared biology and environment, we examined which components of the social environment impact health, and how the effects vary with age, in dogs. We first drew on detailed survey data from owners of 27,547 dogs from the Dog Aging Project and identified six factors that together explained 35% of the variation in dog's social environment. These factors all predicted measures of health, disease, and mobility, when controlling for dog age and weight. Factors capturing measures of financial and household adversity were linked to poorer companion dog health, while factors associated with the social companions, like dogs and adults, were linked to better health. Interestingly, some of these effects differed across a dog's lifespan: for instance, the effect of neighborhood disadvantage on disease instances was strongest in older dogs. Together, our findings point to similar links between adversity and health in companion dogs, and set up future work on the molecular and biological changes associated with environmental variation in order to identify ways to mitigate or even reverse the negative environmental effects.

THE MODIFIED MINI MENTAL STATE (3MS) TEST - DEVELOPMENT OF AN ONLINE TRAINING PROGRAM

Tara Rose,¹ Evelyn Teng,¹ Chia Ying Chen,¹ Elyse Manzo,² Katherine Erickson,³ and Helena Chui,¹ 1. *University of Southern California, Los Angeles, California, United States*, 2. *University of Southern California, Huntington Beach, California, United States*, 3. *University of Southern California, Moraga, California, United States*

The Modified Mini Mental State (3MS), a screening test for cognitive abilities, can be administered in approximately 10 minutes and has a score range of 0-100. Early detection of cognitive impairment is important for clinical care. An individual's score change over time can also help assess disease progression and treatment effects. The Web of Science, an online database, reports 1,864 publications using the 3MS, including 412 in the last 5 years. Articles came from 52 countries in 7 continents, with languages in English (98.7%), French (0.5%), Spanish (0.5%), German

(0.2%), Czech (0.1%), and Korean (0.1%). The fields that publish with 3MS data included Geriatrics/Gerontology, Neurosciences/Neurology, Psychiatry, Psychology, and General/Internal Medicine. One reason for the popularity of the 3MS is its detailed manual for test administering and scoring; however, to date the manual is available only in print form. Here we present an online training program. It includes detailed directions on administering and scoring, video of a 3MS administration, and post-training tests on a trainee's competency. This training material also covers clinical benefits of cognitive screening and a comparison of the 3MS with other measures. The 3MS helps clinicians with early detection of cognitive impairment, allowing time to address its underlying and potentially reversible causes, and aids in disease management. This online training program will help ensure accuracy and reduce between-tester variability of the obtained scores in both clinical care and research studies.

THE RELATIONSHIP BETWEEN DEMENTIA SEVERITY & CAREGIVER PREFERENCES FOR DECISION MAKING ROLE REGARDING MAMMOGRAPHY

Molly Frank,¹ Seho Park,² Kathleen Lane,³ Alexia Torke,¹ Mara Schonberg,⁴ Greg Sachs,¹ Peter Schwartz,⁵ and Nicole Fowler,¹ 1. *Indiana University School of Medicine, IU Center for Aging Research, Indianapolis, Indiana, United States*, 2. *Department of Biostatistics, School of Medicine, Department of Biostatistics, School of Medicine, Indiana, United States*, 3. *Indiana University School of Medicine, Indianapolis, Indiana, United States*, 4. *Beth Israel Deaconess Medical Center, Boston, Massachusetts, United States*, 5. *Center for Bioethics, Indianapolis, Indiana, United States*

The incidence of Alzheimer's disease and related dementias (ADRD) and breast cancer increases with age. Despite being one of the most effective ways to diagnose breast cancer early, mammography in ADRD patients comes with an increased risk of treatment complications and false-positive results. Family caregivers are often involved in the decision-making process, and this study evaluates the relationship between dementia severity and caregiver preferences when making decisions about mammography with the patient alone, and with the patient and doctor. We included 181 caregivers from the Decisions about Cancer screening in Alzheimer's Disease trial, which uses the Dementia Severity Rating Scale (DSRS) to assess dementia severity and a modified Control Preferences Scale (CPS) to assess each caregiver's preferred decision-making approach. Multinomial logistic regression models evaluated the relationship between DSRS and CPS categories (active, passive, and collaborative), while controlling for the caregivers' age, sex, race, education, and relationship to patient. Model 1 examined the caregivers' preferred role with the patient, and it found a significant association between increased dementia severity and preference for a collaborative approach ($p < 0.001$) or passive approach ($p < 0.05$) compared to an active approach. Model 2 did not find a significant association between dementia severity and the caregivers' preferred role when making decisions with the patient and doctor; however, those with increased age and education were more likely to prefer an active role. The association between dementia severity, caregiver characteristics,

and decision-making preferences supports the need for approaches to support ADRD caregivers with medical decision making.

THE RELATIONSHIP BETWEEN PROTEIN INTAKE AND GUT MICROBIOTA IN COMMUNITY-DWELLING OLDER MEN FROM THE MROS STUDY.

Samaneh Farsijani,¹ Jane Cauley,¹ Shyamal Peddada,² Lisa Langsetmo,³ James Shikany,⁴ Kristine Ensrud,⁵ Eric Orwoll,⁶ and Anne Newman,¹ 1. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*, 2. *NIH, BETHESDA, Maryland, United States*, 3. *University of Minnesota, University of Minnesota, Minnesota, United States*, 4. *University of Alabama at Birmingham, Birmingham, Alabama, United States*, 5. *University of Minnesota, Minneapolis, Minnesota, United States*, 6. *Oregon Health & Science University, Portland, Oregon, United States*

Despite growing evidence supporting the role of protein consumption in promoting muscle health, the possible mediation by gut microbiota remains unclear. Here, we determined the association between the quantity of dietary protein and gut microbiome composition in community-dwelling older adults. We performed a cross-sectional analysis on 775 older men from the Osteoporotic Fractures in Men (MrOS) study with available dietary information and stool samples at visit 4 (2014-16). Protein intake extracted from a brief Food Frequency Questionnaire and adjusted to total energy intake using the residual method. Gut microbial taxa were determined by 16S (v4) sequencing (Greengenes references). 11,534 Operational Taxonomic Units were identified and assigned to 21 phyla with dominance of Firmicutes (45%) and Bacteroidetes (43%). We performed distribution-based analysis (α -diversity), distance-based Permutation Multivariate Analysis of Variance (β -diversity), and taxa abundance (by ANCOM-BC R-package) to determine associations between protein intake and gut microbiome. Mean energy-adjusted protein intake was 62.0 ± 10.8 g/d [0.8 ± 0.3 g/kgBW/d]. Participants with higher protein intake had higher Shannon and Chao1 α -diversity indices ($P < 0.05$). For β -diversity analysis, participants with higher protein intake had a different center in weighted and unweighted UniFrac PCoA vs. those with lower intake ($P < 0.05$) adjusted for age, race, clinical center, energy intake, weight, height, and medications. Tenericutes phylum and several genus-level OTUs, including Klebsiella, Tyzzerella, Christensenellaceae, Ruminococcaceae, Blautia, and Veillonella were differentially abundant between quartiles of protein intake (FDR corrected $P < 0.05$). Our data support an association between dietary protein and gut microbiota diversity, a relationship that could potentially influence physical function and sarcopenia development.

THE ROLE OF OCCUPATIONAL SWITCHING ON RETIREMENT OF AMERICAN MIDLIFE WORKERS

Yun taek Oh, *University of Minnesota, Minneapolis, Minnesota, United States*

An increasing number of midlife Americans are financially unprepared for retirement. This is a problem because of the increasing life expectancy that prolongs the need for financial resources. One way to resolve this problem is to postpone full

retirement by having bridge jobs that provide more time to work and accumulate retirement savings. While having a bridge job means numerous labor market behavior such as working for different employers and reducing work hours and intensity, there is a limited number of studies focused specifically on how switching occupations can contribute to retirement decisions with a longer time frame. This study investigated the association between occupational switching and retirement patterns of American midlife workers aged between 50 to 59 years using the Health and Retirement Study longitudinal data from 2004 to 2016, Occupational Information Network data, and American Community Survey from 2003 to 2016. The changes in occupational demandingness before and after switching occupations were reflected by using mover design event study regression with fixed effects. In general, occupational switching is associated with later retirement until two to three years after switching occupations for both genders, yet this association varies by the directions of the change in occupational demandingness.

TOUCHSCREEN TECHNOLOGY TO IMPROVE DEMENTIA CARE MANAGEMENT FOR OLDER ADULTS LIVING IN THE COMMUNITY

Ellen Brown,¹ Nicole Ruggiano,² mariateresa H. Munoz,³ lisa Roberts,³ C. Victoria Framil,³ Bernardo Arroyo,³ and Michelle Bourgeois,⁴ 1. *Florida International University, Miami, Florida, United States*, 2. *University of Alabama, Hoover, Alabama, United States*, 3. *Florida International University, Florida International University, Florida, United States*, 4. *University of South Florida, Tampa, Florida, United States*

Chronic disease management challenges for persons living with dementia (PLWD) often includes difficulties communicating how their feeling or describing symptoms to caregivers. To address this issue, an interdisciplinary team is developing a touchscreen mobile technology that will allow the assessment of clinical information about the PLWD, such as sleep quality, appetite, pain level, and mood. The mobile technology also allows caregivers to share this information with providers in real-time from their homes. In the team's effort to incorporate a graphic measure to assess mood into the technology, a literature review revealed no such measurement tool has been established and validated for assessment with PLWD. This study focused on developing a graphic clinical assessment tool that can be used to assess mood for PLWD and establishing the face and content validity for this assessment tool. A team that included multidisciplinary clinical experts and a graphic artist designed a series of pictures of facial expressions and body language depicting a continuum of mood states (i.e., happy through depressed). The research team consulted with existing artistic depictions of sadness expression, including medical illustrations depicting depression. Multiple iterations have resulted in a series of images that represent moods from happy to very sad. The team considered a number of factors in developing the images including gender, ethnicity, and race. Consensus on the construct validity was achieved by the expert clinical panel. Details of a follow-up study to evaluate construct validity will be presented.

TRANSLATING AND ADAPTING THE MODIFIED MINI MENTAL STATE (3MS) TEST FOR MULTIPLE CULTURAL POPULATIONS

Tara Rose,¹ Evelyn Teng,¹ Katherine Erickson,² Chia Ying Chen,¹ Elyse Manzo,³ and Helena Chui,¹

1. *University of Southern California, Los Angeles, California, United States*, 2. *University of Southern California, Moraga, California, United States*, 3. *University of Southern California, Huntington Beach, California, United States*

Within healthcare settings, screening of cognitive abilities in older adults is routinely conducted for the detection, early intervention, and management of cognitive impairments. The Modified Mini Mental State (3MS) test takes approximately 10 minutes to administer and has a score range of 0 - 100. It can provide an estimated MMSE score, and has been used in multiple countries since 1987 with approximately 1,900 publications. The United States has many diverse populations with different languages and cultural backgrounds. How to appropriately translate and adapt the original 3MS test in English for each minority group in order to better serve them is an important issue. Cross-cultural assessment involves much more than accurate translation of test items across languages. One needs to know not only the oral and written languages involved, but also the life experiences and circumstances of the target populations. This presentation first covers some general considerations in test translation and adaptation, including attention to cultural, ecological, and language specifics. We shall then present Chinese, Korean, and Hindi 3MS record forms to illustrate the reasons and ways for modification of some of the test items. To accommodate different writing systems, for example, 3MS test versions with an alphabet are different from ones with logographic character representations. Modifications of the 3MS items include those on temporal orientation, spatial orientation, naming, and repetition. In summary, cultural, ecological, and linguistic differences must be taken into account for cognitive screening in order to enhance cross-population comparability and be more inclusive for aging ethnic minorities.

TRANSNATIONAL CAREGIVING FOR OLDER ADULTS AND CAREGIVERS' WELLNESS IN JAPANESE AMERICANS DURING THE PANDEMIC

Kazumi Hoshino,¹ Winston Tseng,¹ and Kei Kamide,² 1. *The University of California at Berkeley, Berkeley, California, United States*, 2. *Osaka University, Suita, Osaka, Japan*

Global migration has greatly affected intergenerational family support beyond national borders, in particular adult children's transnational family caregiving for elderly parents. Specifically, the COVID-19 pandemic has largely influenced transnational caregiving due to the travel restrictions. Transnational caregiving for older adults includes adult children's periodical returning to their home country and/or adult children's caregiving for their parents in their settled country. The goal of this study was to identify trajectories between adult children's transnational caregiving for their parents and caregivers' wellness in Japanese Americans before and during the pandemic. We conducted semi-structured interviews with Japanese Americans 40 to 59 years of age (N=20) in California before the lockdown and during the increasing number of patients infected with the Delta variant. The qualitative data analysis showed some Japanese Americans periodically returned to Japan to provide caregiving for their parents before the pandemic, while others didn't. However, the former group currently relied on their families in their home country more than before. The limitations led to not only distress over uncertainty but also release from a strong sense of reciprocity and filial responsibility, by

changing from physical support to emotional and financial support via online. They also enhanced cultural identity as Japanese Americans, by thriving from discrimination against Asian Americans. Thus, our findings demonstrate important factors that impacted on transnational caregiving and caregivers' wellness, including cultural identity, family norms, beliefs and practices of intergenerational support, social and historical contexts, financial remittance, ICT use, and healthcare policies among the underrepresented populations across the Pacific.

TREHALOSE ENHANCES LONG-TERM RECOVERY IN 18-MONTH-OLD MICE BY INCREASING AUTOPHAGY AFTER TRAUMATIC BRAIN INJURY

Rodney Ritzel, Yun Li, Jordan Carter, Niaz Khan, Junyun He, Samantha Allen, Alan Faden, and Junfang Wu, *University of Maryland School of Medicine, Baltimore, Maryland, United States*

Older patients with traumatic brain injury (TBI) have higher mortality and poorer long-term outlook compared to younger individuals. This may contribute to the assumption that aggressive management of geriatric TBI is futile. The present study examined the long-term recovery potential and underlying mechanisms associated with advanced age in male C57BL/6 mice using a controlled cortical impact model of TBI. Older (18 mos) mice had higher mortality compared to younger (10 wks) mice at 12 weeks post-injury. While aging alone had a profound impact on behavioral ability, the recovery slope in some, but not all, neurobehavioral tests was relatively similar between young and old injured mice. NanoString analysis identified several age- and injury-specific genes that were differentially expressed, including those involved with the complement, phagocytosis, and autophagy pathways. Flow cytometry demonstrated dysregulation of autophagic function in microglia with normal aging which was exacerbated after TBI. Given the critical role for autophagy in promoting the cellular degradation of cytoplasmic materials, we reasoned that treatment with the autophagic inducer, trehalose, may be a viable therapeutic strategy. Trehalose was administered in the drinking water (3%) starting at d1 post-injury up to 8 weeks. Older TBI mice treated with trehalose exhibited either delayed deficits or enhanced recovery in cognitive and motor tasks. Trehalose modified expression of autophagy markers and reprogrammed the microglial response to TBI. Our data indicate that microglia undergo chronic changes in autophagic regulation that are associated with poor outcome. Boosting autophagy may be a promising therapeutic strategy for older TBI patients.

UNDERSTANDING OLDER ADULTS MOTIVATIONS AND PREFERENCES FOR A MEDICATION ADHERENCE APP

Olivia Kupiec,¹ Maurita Harris,² and Wendy Rogers,³
1. *University of Illinois Urbana Champaign, Chicago, Illinois, United States*, 2. *University of Illinois at Urbana-Champaign, Champaign, Illinois, United States*, 3. *University of Illinois Urbana-Champaign, Champaign, Illinois, United States*

As the percentage of older adults with hypertension continues to increase, medication adherence remains low. However, medication adherence can potentially be improved

through the use of medication reminder apps. Medication reminder apps contain numerous features that enable older adults to remember to take their medication, such as providing alerts to take their medication, reminding them when to refill their prescription, and more. Despite being aware of these apps, many older adults lack the motivation needed to use them continuously. We recruited 9 participants (60 years or older) who currently take medication for a chronic condition. Using a mixed-methods approach, we gathered quantitative survey data using the TechSAge Demographic Background, Motivation, and Behavior Change Technique Questionnaires). Qualitative data were gathered through a semi-structured interview that asked questions about general motivations and preferences in addition to engaging participants in co-designing a medication adherence app. Results from the interview were analyzed through a thematic analysis that identified comprehension and preferences of older adults in medication reminder app usage. We tested five different intrinsic motivation factors, and results indicate older adults are most motivated intrinsically due to perceived choice, perceived competence, value/usefulness, effort/importance, and pressure/tension. We also tested five factors of extrinsic motivation, and results indicate older adults are most motivated extrinsically due to introjected regulation, reward-driven, external regulation, compliance, and identification. These data provide insights to guide the design of medication reminder apps to support older adults in the self-management of their chronic conditions.

UNDERSTANDING THE PREDICTIVE FACTORS THAT INFLUENCE THE PERCEIVED BURDEN OF DEMENTIA CAREGIVERS

Kaitlyn Lucas,¹ and Katherine Judge,² 1. *Cleveland State University, Westlake, Ohio, United States*, 2. *Cleveland State University, Cleveland, Ohio, United States*

Caregivers of individuals with dementia have increased levels of burden because of their caregiving duties which in turn results in negative effects on their physical, emotional, and mental wellbeing. Few studies have examined individual difference-based constructs such as positive and negative affect in relation to caregiver burden. Positive affect is characterized by pleasant emotions and expressions and higher levels of overall life satisfaction whereas negative affect is characterized by more pessimistic emotions and expressions and lower overall life satisfaction. Analyses were performed on dementia caregivers (n=102) using the online data collection tool MTurk Prime. The average caregiver provided 21 or more hours of care with 76.9% of caregivers living with their loved one with dementia. Significant correlations were found between caregiving burden and positive affect ($r = -.31, p = .002$) and negative affect ($r = .56, p < .001$), with higher positive affect related to lower burden and higher negative affect related to greater burden. Results of multiple regression models showed that positive affect ($\beta = -.24, p = .03$) and negative affect ($\beta = .35, p = .01$) were significant predictors of burden even while controlling for other constructs including types of coping, compassion towards other, and assessment of family dynamics. Understanding the relationship between these constructs will allow for more individualized interventions to be created to help reduce the level of burden that dementia caregivers experience.

UNDERSTANDING THE ROLE OF COMMUNICATION TECHNOLOGY IN FACILITATING SOCIAL CONNECTIVITY AND ADDRESSING LONELINESS

George Mois,¹ Jenay Beer,² Kerstin Emerson,² and Tiffany Washington,² 1. *University of Illinois, Champaign, Illinois, United States*, 2. *University of Georgia, Athens, Georgia, United States*

In the United States, two out of five adults report feelings of loneliness. The involvement of communication technologies presents a promising potential in helping improve social connectivity and address the experience of loneliness. However, the sense of presence (embodiment) users are able to achieve through the technologies can vary depending on their abilities and functions. The present study identified user characteristics associated with an interest to adopt telepresence technologies (e.g., videoconferencing, smart displays, robots) across various levels of embodiment. The data for this study were collected using a Qualtrics survey which was distributed via Amazon Mechanical Turk. The participants recruited for this study were between the ages of 18-78 years old, constituting a total sample size of 384 participants. The data were analyzed using four logistics regression models. The dependent variables aimed to identify participants' interest to adopt telepresence technologies across varying embodiment levels. Across the lifespan older adults were significantly more likely to report lower rates of overall loneliness than young and middle-aged adults. Our findings indicate that those interested in adopting communication technologies with higher levels of embodiment had significantly higher odds of reporting being divorced or widowed (OR=4.12, $p<.05$), reside in a rural community (OR=2.20, $p<.05$), and report higher rates of emotional loneliness (OR=1.20, $p<.05$). Across the four models, there was no significant difference in participants' interest to adopt telepresence technologies. These results suggest that the sense of presence achieved across the various types of communication technologies may help address feelings of loneliness and support healthy aging.

USE OF LONG-TERM CARE DECREASED OVER TIME AMONG THE OLDEST-OLD WITH AND WITHOUT DEMENTIA - A REGISTER-BASED STUDY

Mari Aaltonen,¹ Leena Forma,² Jutta Pulkki,¹ Jani Raitanen,¹ and Marja Jylhä,¹ 1. *Tampere University, Tampere University / Tampere, Pirkanmaa, Finland*, 2. *University of Helsinki, University of Helsinki / Helsinki, Uusimaa, Finland*

Care policies for older adults emphasize aging-in-place and home care over residential long-term care (LTC). We explore how the use of residential LTC in the last five years of life among people with and without dementia changed between those who died in 2001, 2007, 2013, and 2017 in Finland. Retrospective data drawn from the national health and social care registers include all those who died aged 70+ in 2007, 2013, and 2017, plus a 40% random sample from 2001 (N=128 050). Negative binomial regression analysis was used to estimate the association of dementia with LTC use during the last five years of life (1825 days). The independent variables included dementia, age, marital status, annual income, education, and chronic conditions. In the total study population, the proportion of LTC users and the mean

number of days in LTC increased until 2013, after which it decreased. Changes in LTC use differed between different age groups and by dementia status. Over time, the decrease in round-the-clock LTC use was steep in those aged 90+ with dementia and in people aged 80+ without dementia. The individual factors related to morbidity and sociodemographic factors did not explain these results. The changes in LTC care policy may have contributed to the decrease in LTC use among the oldest. However, according to national statistics, the availability of formal home care has not increased. This development may suggest that the oldest-old and those with dementia – a highly vulnerable group – are left without proper care.

USING DIAGNOSTIC ULTRASOUND TO SUPPORT THE DIAGNOSE SARCOPENIA IN OLDER ADULTS: A SYSTEMATIC REVIEW

Edgar Vieira, Lily Charles, Monica Cortes, and Tabitha Lees, *Florida International University, Miami, Florida, United States*

Dual-energy x-ray absorptiometry (DXA) is currently the gold standard for diagnosing loss of muscle mass in older adults (a component of sarcopenia diagnosis). Magnetic resonance imaging (MRI) and computed tomography (CT) have also been used successfully. Due to elevated costs, limited access, exposure to radiation, and increased difficulty of operation, other methods have been explored as alternatives. We reviewed the literature on the use of diagnostic ultrasound to assist in the diagnose sarcopenia in older adults by searching MEDLINE, Embase, and CINAHL using a variation of terms related to “ultrasound”, “sarcopenia”, and “older adults”. We included studies that included older adults over the age of 60. Eighteen studies were included after screening for eligibility and conducting full-text reviews. The most common transducer head frequency utilized in the studies were 5-12 and 8 MHz (three studies each), followed by 5, 6, and 7.5 MHz (two studies each). The most common musculature examined was anterior thigh musculature, followed by muscles of the lower leg, upper extremity, abdominals, and head/neck. Measurements most taken were muscle thickness/cross sectional area (18 studies), followed by muscle echogenicity (9 studies), and pennation angle (3 studies). Ultrasound is a reliable and valid tool to examine muscle thickness to assist in diagnosing sarcopenia. However, echogenicity measures of a muscle were not reliable. Further research is needed with increased sample size and variance amongst subjects to generalize and create normative data. In addition, standardized protocols for the use of ultrasound to assist in the diagnosing sarcopenia need to be established.

VISUALIZING PERSON-CENTERED LONG-TERM CARE: AN EXPLORATORY SCOPING REVIEW AND EVIDENCE MAPPING

Mary Lou Ciolfi,¹ Rocky Coastlines,² Catherine Taylor,³ Kayla Thompson,⁴ Jennifer Crittenden,⁵ Lenard Kaye,⁴ Angela Hunt,⁶ and Paul Nebenzahl,⁷ 1. *University of Maine, Center on Aging, Bath, Maine, United States*, 2. *University of Maine Center on Aging, Bangor, ME 04401-4324, Maine, United States*, 3. *University of Maine Center on Aging, Bangor, Maine, United States*, 4. *University of Maine, Bangor, Maine, United States*, 5. *University of Maine,*

University of Maine, Maine, United States, 6. The Cedars, Portland, Maine, United States, 7. The Mayer-Rothschild Foundation, Chicago, Illinois, United States

Despite decades of professional, academic, and policy interest in person-centered long-term care (LTC), the field continues to be challenged by the absence of a comprehensive depiction of the concept and a lack of consistency reflected across studies and measures. In response, a participatory action, research-focused, partnership between an institution of higher education and an LTC community (the University of Maine Center on Aging and The Cedars), with funding from The Mayer-Rothschild Foundation, is identifying and mapping the landscape of person-centered LTC in nursing homes and assisted living communities. A collaborative, ongoing, exploratory scoping literature review and evidence mapping has compiled a database of 663 academic and 115 grey literature articles through 65 systematic searches reviewing over 4,296 articles. An iterative process from both the resident and organizational perspectives revealed nine core domains (e.g. dining, resident care, environment, quality improvement, identity and personhood, etc.) and two substantive research gaps (the intersection of person-centered long term care with diversity, equity, and inclusion issues, and pandemic considerations). For mapping purposes, domain content was analyzed categorically based on concept, information revealed about resident, family, and staff experience, and operations applicability. The identified person-centered LTC domains, categorical analysis, identified gaps, and visual representation via mapping will contribute to generating research ideas, supporting the development of effective operationalization for LTC settings, and contributing to an understanding of the theoretical scope and concrete elements of a person-centered care model that aims to improve the wellbeing and quality of life of older adults in long-term residential settings.

WHAT HAPPENS WHEN THE PATIENT DOESN'T DIE? UNDERSTANDING LIVE DISCHARGE FROM HOSPICE CARE

Stephanie Wladkowski,¹ Kathryn Coccia,² Anna Wingo,³ Ruaa Al-Juboori,⁴ and Cara Wallace,² 1. *Eastern Michigan University School of Social Work, Eastern Michigan University, Michigan, United States, 2. Saint Louis University, St. Louis, Missouri, United States, 3. Saint Louis University, Saint Louis University, Missouri, United States, 4. Saint Louis University, Saint Louis, Missouri, United States*

Hospice has been shown to improve end-of-life outcomes, yet with eligibility limited to a six-month prognosis, the hospice system is not structured to meet longer-term needs. Though hospice is strongly associated with death, some enrolled patients do not decline as predicted leading to what is referred to as a 'live discharge.' In 2018, 6.3% of all hospice discharges were patients discharged alive due to decertification, or no longer meeting eligibility requirements. The aim of this presentation is to review current literature surrounding live discharge, discuss policy and practice challenges within current discharge practices, and present new research directions from two current NIH-funded studies. Studies of live discharge often do not differentiate between revocation and decertification, yet these are very different phenomena, particularly regarding decision making. Patients discharged from hospice are often referred to as "not dying fast enough," or

"failure to die on time," yet, they are still dying from chronic illness, just outside the prescribed six-month framework. Affected patients lose access to important supportive services and resources, still require substantial care, and can struggle to process feelings of abandonment and uncertainty. Further, an increased burden is placed on primary caregivers who may be unprepared for this transition. Clinicians across agencies report great variability in managing live discharges with no standardized protocols. These findings demonstrate the complexities of live discharge, the need for more research to support a standardized and reimbursable discharge process and to define unmet needs for both patients and caregivers affected by live discharge.

WORKING AND CARING DURING THE CORONAVIRUS PANDEMIC: THE IMPACT OF WORKPLACE POLICY ON WORKING FEMALE CAREGIVERS

Jessica McLaughlin,¹ Ashley Taeckens-Seabaugh,² Amy Kennicutt,³ and Taylor Capellaro,⁴ 1. *University of Denver, Fort Collins, Colorado, United States, 2. University of Denver, Denver, Colorado, United States, 3. Data 4 Equity, LLC, Miami Beach, Florida, United States, 4. Connally Counseling, Garden City, Michigan, United States*

The unprecedented nature of the coronavirus pandemic created significant socioenvironmental changes for working caregivers who found themselves juggling a new landscape of working and caring. Changes in workplace policy were often intended to accommodate those with caring responsibilities, however, there is little information available on how working female informal caregivers of older adults (defined as individuals age 50 or older) received, interpreted, and experienced those policy changes. Given this, it is necessary to gather a complete picture of workplace policy in the daily lives of working female caregivers during the pandemic. This qualitative study involved interviews held between February and April 2021 via video conferencing technology with 29 working female caregivers, ranging in age from 27 to 75 years old. Using a Role Conflict framework and descriptive, structural, and emotion coding strategies, analysis of written transcripts revealed that, while many caregivers were grateful that their workplaces had become more accommodative during the pandemic, apprehension and uncertainty about the future, both with caregiving and with work, also weighed heavily on many of them. The most positively endorsed workplace policy changes were flexibility in work schedules and the ability to work remotely during the pandemic. This research elucidates policy implications for working female caregivers outside of the pandemic context, as many of these policies enabled caregivers to provide care while working with greater ease.

Session 9510 (Late Breaking Poster)

Late Breaking Poster Session III

A QUALITATIVE ANALYSIS OF DIETARY PRACTICES AND MOTIVATORS AMONG OLDER ADULTS LIVING WITH PARKINSON DISEASE

Christine Ferguson,¹ Jeannine Lawrence,² Joy Douglas,² Seung Jung,² Anne Halli-Tierney,³ Chuong Bui,⁴

Kyndal Oden,² and Amy Ellis,² 1. *University of Alabama at Birmingham, Tuscaloosa, Alabama, United States*, 2. *University of Alabama, Tuscaloosa, Alabama, United States*, 3. *The University of Alabama, Tuscaloosa, Alabama, United States*, 4. *University of Alabama, University of Alabama, Alabama, United States*

Research supports the role of diet in the onset and progression of Parkinson disease (PD); however, there is no specific dietary pattern recommended for PD. This is partially due to a paucity of in-depth data on the dietary practices of this population. Therefore, the purpose of this study was to qualitatively explore the dietary practices and motivators of older adults with PD. Eleven dyadic semi-structured interviews with older adults and their care-partners were conducted via Zoom about their dietary practices and motivators. Interviews were audio-recorded and transcribed verbatim, and data were thematically analyzed using NVivo 12 software. The following themes were identified: 1) Intentionally making healthier choices on a regular basis; 2) Following a specific dietary pattern; for example, the Mediterranean diet, ketogenic diet, vegetarian diet, and/or intermittent fasting; 3) Limiting or avoiding certain foods, food components, and/or food groups, such as dairy, gluten, sugar, animal meat, and/or alcohol; 4) Purchasing or growing organic produce; and 5) Adjusting the timing of their protein intake to their medications. Their PD diagnosis and symptoms were reported as the primary motivators for following their respective diets. Overall, older adults with PD may be motivated by their diagnosis to modify their dietary intake; however, there are a variety of patterns or restrictions they may be adhering to. These results support the need for a consensus on the dietary recommendations for this patient population.

A REMOTE TAI CHI PROGRAM FOR DIVERSE OLDER ADULTS WITH MULTISITE PAIN DURING THE COVID-19 PANDEMIC

Yael Koren,¹ Suzanne Leveille,¹ Catarina Ambrizzi Moraes,¹ William Butts,¹ Peter Wayne,² Gloria Yeh,³ and Tongjian You,¹ 1. *University of Massachusetts Boston, University of Massachusetts Boston, Massachusetts, United States*, 2. *Harvard Medical School, Chestnut Hill, Massachusetts, United States*, 3. *Harvard Medical School, Boston, Massachusetts, United States*

The goal of this study was to evaluate feasibility and acceptability of a remote Tai Chi program in diverse older adults with multisite pain and risk for falls during the COVID-19 pandemic. Adults aged ≥ 65 y living in diverse Boston neighborhoods were invited through mailed letters to participate in a recruitment and screening survey. Eligible adults were re-contacted to join a 4-week Tai Chi or light exercise program offered online twice weekly. We conducted pre- and post-interviews to assess pain characteristics, fall risk, computer use, and satisfaction with the program. Primary outcomes were class attendance, experience, and program safety. Among 335 survey respondents, 105 (31%) were eligible based on multisite pain and fall history or cane/walker use. Of the eligible respondents, average age was 74y, 75% were women, 62% were Black, and 31% had high school education or less. We assigned 32 participants to 4 Tai Chi (Yang-style Tai Chi tailored to older adults with pain) or 2 light exercise (stretching and strength exercise) groups

conducted via zoom; of these, 24 (75%) completed the program. Overall, 79% attended ≥ 6 of 8 classes. There were no adverse events reported. Regarding experiences with remote exercise, 67% reported it was very easy to join, 88%, very easy to see the instructor and 83%, very easy to participate. For future planning, 29% prefer remote classes, 33% prefer in-person classes, and 38% could do either. In conclusion, remote exercise programming is safe and feasible for diverse older adults who have multisite pain and risk of falls.

A WALK IN THE COUNTRY: STORYING RURAL JOURNEYS OF DEMENTIA CARE

Jami Horne, and Katie Aubrecht, *St. Francis Xavier University, St. Francis Xavier University, Nova Scotia, Canada*

Dementia and dementia caregiving are increasingly recognized as significant public health issues. Dementia may be more prevalent in rural communities; in part due to higher rates of population aging. In Canada the Nova Scotia provincial dementia strategy Towards Understanding (2015) emphasizes the need to address the unique realities of rural dementia care as a priority issue; however, research remains limited on this demographic in the province, and Atlantic Canada more broadly. This presentation shares findings from the Royal Bank of Canada Foundation funded study, Rural Dementia Caregiving: A Community Life Story, conducted in 2021 to address this critical knowledge gap. The qualitative research design involved a narrative review, archival research and narrative analysis of interviews that yielded rich stories of family/friend dementia caregiving in rural Nova Scotia. Stories illustrate how history, culture and identity inform dementia caregiver realities, experiences and self-perceptions. Study results also suggest that rural dementia caregiving is characterized by factors that include strong community networks and deep-rooted connections to land, culture, and heritage, which can be experienced as supportive as well as constraining. The conditions of life in rural communities, including restricted access to internet, transportation, essential services and paid care providers, pose challenges to dementia caregiving. They also provide opportunities in which networks and connections become more visible and may even be strengthened. Findings demonstrate the lived realities of rural dementia caregivers and the people they care for are unique. Addressing their needs require a distinct approach that acknowledges and can appropriately respond to these differences.

“FOR ME, IT’S CONNECTION”: OLDER ADULTS EXPERIENCE WITH TECHNOLOGY DURING COVID-19

Vivian Miller,¹ HeeSoon Lee,¹ and Erin Roark,² 1. *Bowling Green State University, Bowling Green, Ohio, United States*, 2. *Augusta University, Augusta, Georgia, United States*

As a result of COVID-19, older adults have experienced isolation, lost social contacts, and a decrease in connections. A recent study found that “approximately one-quarter of community-dwelling older adults are considered to be socially isolated, and 43% of them report feeling lonely.” Various innovative interventions have emerged, including technology-based interventions as a means to reduce social isolation in older adults, particularly as information communication technology (ICT) use is on the rise among this population.

However, it remains to be known how these connections are faring for older adults in the pandemic and whether these ICT connections lead to greater or lesser feelings of social connectedness. Thirty-nine (N=39) in-depth semi-structured interviews were conducted to explore the lived experiences of technology use among older adults during COVID-19. Participants' experiences with ICT ranged from illiterate to savvy. Most participants indicated Zoom was the primary means to stay socially connected to family and friends. Participants emphasized that ICT may be a possible solution to deal with loneliness for those older adults who are especially isolated due to COVID-19 restrictions. Barriers and challenges to ICT use included taking too much time to use and needing help to fix any problems that arose. Finally, participants shared essential aspects of ICT use, revealing that it was 'technology or nothing.' Findings from this study indicate a need for a simple ICT for the older adult population. Moreover, findings suggest opportunities for peer-support ICT training programs for older adults.

ADAPTING PSYCHOTHERAPY FOR COMORBID SUBSTANCE USE AND BIPOLAR DISORDER IN OLDER SEXUAL MINORITIES: A CASE STUDY

Sarah Nanami Morehouse,¹ Ashley Stripling,² Kirenia Brunson,¹ Jodie Maccarrone,¹ Jessica Choe,¹ Julian Garcia,¹ and Nicholas Boston,¹ 1. *Nova Southeastern University, Davie, Florida, United States*, 2. *Nova Southeastern University, Fort Lauderdale, Florida, United States*

Approximately 65 to 95% of individuals with bipolar disorder (BD) are diagnosed with an additional psychiatric condition (Kessler, 1999). Alcohol, the most commonly abused substance amongst individuals with BD (Xiao et al., 2016), has been linked to significant increases in suicide attempts, disability, hospitalizations, and mortality (Baldessarini et al., 2008; Goldberg et al., 1999; Mitchell et al., 2007; Nery & Soares, 2011). Despite these ill effects, little is known about how to effectively treat, or adapt existing treatment appropriately, for the growing numbers of individuals who are dually diagnosed with BD and alcohol use disorder (AUD) and hold the identity of lesbian, gay, bisexual, transgender, or queer (LGBTQ) in late life. Thus, the purpose of this study is to demonstrate how treatment was adapted to a self-identified gay man with comorbid BD and AUD from a relational, culturally sensitive perspective while simultaneously implementing two short-term interventions: cognitive behavioral therapy (CBT) and a behavioral substance use program. In line with Knight & Poon's (2008) Contextual Life Span Theory for Adapting Psychotherapy with Older Adults (CALTAP) and a multicultural lens that incorporates relevant research on older LGBTQ individuals, modifications were made to the content, structure, language, and duration of therapy while cultivating a safe and empathic space. Idiographic data and progress monitoring measures suggests treatment resulted in substance use and distress reduction, as well as mood stabilization. However, additional booster sessions may be advantageous given the risk for substance abuse relapse and the compounding effect it may exert on persons with BD.

ADRD CAREGIVING EXPERIENCES AND HEALTH BY RACE, ETHNICITY AND CARE RECIPIENT GEOGRAPHIC CONTEXT

Tiffany Kindratt,¹ Dominique Sylvers,² Aya Yoshikawa,³ Mónica López Anuarbe,⁴ Noah Webster,⁵ and

Erin Bouldin,⁶ 1. *University of Texas at Arlington, Arlington, Texas, United States*, 2. *University of Michigan School of Public Health, University of Michigan Institute for Social Research, Michigan, United States*, 3. *Texas Woman's University, Texas Woman's University, Texas, United States*, 4. *Connecticut College, New London, Connecticut, United States*, 5. *University of Michigan, Ann Arbor, Michigan, United States*, 6. *Appalachian State University, Boone, North Carolina, United States*

Few studies have examined how the intersectionality of geographic context and race/ethnicity influences Alzheimer's disease and related dementia (ADRD) caregiving. Our aims were to determine whether 1) caregiver experiences and health differed across urban and rural areas; and 2) these links were moderated by caregiver race/ethnicity. We used data from the 2017 National Health and Aging Trends Study and National Study of Caregiving. The sample included caregivers (n=808) of care recipients ages 65+ with 'probable' ADRD (n=482). Geographic context was defined as care recipient's residence in metro (urban) or non-metro (rural) counties. Outcomes included caregiving experiences (burden, gains, life impacts, service/resource use) and health (self-rated, anxiety, depression symptoms, chronic health conditions). Bivariate analyses indicated that non-metro ADRD caregivers were less racially/ethnically diverse (82.7% white) and more were spouses/partners (20.2%). Among racial/ethnic minority ADRD caregivers, non-metro context was associated with having more chronic conditions ($p < .01$), providing less care ($p < .01$), and not co-residing with care recipients ($p < .001$). Amid white ADRD caregivers, non-metro context was associated with not reporting caregiving was more than they could handle ($p < .05$) and finding financial assistance for caregiving ($p < .05$). Multivariate regression analyses demonstrated that non-metro minority ADRD caregivers had 3.09 times higher odds (95% CI=1.02-9.36) of reporting anxiety in comparison to metro minority ADRD caregivers. Geographic context shapes ADRD caregiving experiences and caregiver health differently across racial/ethnic groups. Despite higher rates of ADRD and ADRD-related mortality in non-metro areas, findings suggest both positive and negative aspects of caregiving among White, Black, and Hispanic ADRD caregivers.

AGE DIFFERENCES IN ANTICIPATED USE OF VIRTUAL HEALTHCARE SERVICES AFTER THE PANDEMIC

Matthew Murphy,¹ William Hills,¹ and Karen Hills,² 1. *Coastal Carolina University, Conway, South Carolina, United States*, 2. *Beaufort Jasper Hampton Comprehensive Health Services, Conway, South Carolina, United States*

Healthcare has undergone a significant transformation during the pandemic, with virtual services being rapidly developed and implemented to keep pace with societal needs. This study documented this change in healthcare by examining access and use of video-based, virtual service use before and during the pandemic. Participants for the study (n = 685) included three groups, including retirement-aged persons, middle-aged adults, and traditional college-aged students. Measures for the study included access to and utilization of physical and mental health services, satisfaction with services accessed, and anticipated access and use of virtual

services following the pandemic. Results showed that most participants (94.2%) believed that virtual healthcare would persist after the pandemic; three-quarters of adults (75.2%) but only half of college-aged (52.8%) and retirement-aged (57.6%) participants anticipated using virtual healthcare in the future. Prior use and satisfaction with virtual healthcare services mediated anticipated future use for retirement-aged participants ($p < .001$), but only satisfaction with virtual healthcare was a marginal predictor for college-aged participants ($p = .051$), and neither were predictors for adult-aged participants. These results support that people believe virtual healthcare will persist after the end of the pandemic, but that there are age-related differences in who anticipates using these services in the future, and which factors will make the most difference in attracting clients. These differences can impact how healthcare providers market and develop further tele-health services to increase the likelihood of use by retirement-aged participants, and suggests that client satisfaction is a key mediator for different age groups.

AGE DIFFERENCES IN THE ASSOCIATION BETWEEN CARDIOVASCULAR DISEASE, DEPRESSION, AND SUICIDE RISK

Ruifeng Cui,¹ Alaa Shalaby,¹ Armando Rotondi,¹ Amy Albright,² and Judith Callan,¹ 1. VA Pittsburgh Healthcare System, Pittsburgh, Pennsylvania, United States, 2. VA Maine Healthcare System, Lewiston, Maine, United States

Cardiovascular disease (CVD) is prevalent among older adults aged 60+ (75%). The literature shows a strong bidirectional association between risk for CVD and risk for depression, although there is limited research regarding whether the strength of this association differs by age. CVD may also be related to suicide risk; however, the literature is both limited and mixed, with studies inconsistently finding an association. Additionally, no known studies have investigated age differences in this relationship. The present study examined the association between CVD (assessed via diagnostic checklist), depression (PHQ-8), and suicide risk (SBQ-R), as well as whether these associations differed by age. The current sample consisted of 301 younger adults (aged 18-40) and 432 older adults (aged 60+) recruited online through Mechanical Turk (younger adults: 78.1% white, 46.5% female; older adults 91.4% white, 56.3% female). Older adults had more CVD diagnoses ($M=0.9$) than younger adults ($M=0.3$). The association between CVD (i.e., 1+ CVD diagnoses vs. 0 diagnoses) and mental health was moderated by age (depression interaction $p<.001$; suicide risk interaction $p=.033$). Among younger adults, presence of CVD diagnosis was associated with 85% higher depression symptoms ($M=6.1$ vs 11.3) and 48% higher suicide risk scores ($M=5.8$ vs 8.6) when compared to no diagnoses. CVD had less of a negative impact among older adults and was associated with 64% higher depression symptoms ($M=3.1$ vs 5.1) and only 14% higher suicide risk scores ($M=4.3$ vs 4.9). Providers treating CVD may consider assessing and addressing depression and suicide risk, especially among younger patients with CVD.

AGE, BODY MASS INDEX (BMI) AND COGNITIVE DIFFICULTIES IN APPALACHIAN WEST VIRGINIA

Camila Romero,¹ Moyosoreoluwa Jacobs,² and Bernard Schreurs,³ 1. WVU, West Virginia University,

West Virginia, United States, 2. West Virginia University, Morgantown, West Virginia, United States, 3. WVU, Rockefeller Neuroscience Institute, WVU, West Virginia, United States

Several known factors exacerbate the risk of cognitive difficulties among older adults. In addition to place-based disparities, body weight also predicts cognitive health. In fact, overweight and Obese BMI (Benito-Leon et al., 2013) and underweight BMI (Xiang & An, 2015) are risk factors for cognitive difficulties. Whether the effect of BMI operates similarly across age among adults facing place-based disparities is not clear. In order to better understand the role of BMI among adults already at-risk for health disparities, we used the 2018 BRFSS data to examine the relations among these variables among the 4817 West Virginian adults in the BRFSS database. Approximately 16.5% had difficulty making decisions or remembering. Approximately 73% were overweight or obese, 26% were healthy BMI, and 1% were underweight. A multinomial logistic regression was conducted to examine cognitive difficulties. Healthy BMI and ages 25 – 44 years were the reference groups. The omnibus test was significant, $\chi^2(5, N = 4817) = 38.71, p < 0.0001$. Age and BMI uniquely contributed to the classification. Post hoc inspection of the Odds Ratios showed that adults ages 60 years and older with obesity were 1.27 times more likely to report cognitive difficulties, while those who were underweight were 3.74 times more likely to report cognitive difficulties. That individuals over age 60 with an obese or underweight BMI report more cognitive difficulties highlights the intersection among age, obesity and location on cognitive health disparities in West Virginia.

AGEISM IN HIRING DECISIONS: SENSE OF PURPOSE AS A MITIGATING STRATEGY

Megan Wilson,¹ and Patrick Hill,² 1. Washington University in St. Louis, Saint Louis, Missouri, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States

Discrimination against older adults in the workplace is a pervasive issue that has important consequences for older adults, leading to lower well-being (Stokes & Moorman, 2020) and worse job outcomes (Macdonald & Levy, 2016). One area where discrimination manifests is in hiring practices, and thus research is needed to understand factors that impact willingness to hire older adults. One potential intervention target to reduce age discrimination in hiring is sense of purpose. Sense of purpose manipulations have previously been successful in increasing one's comfort with diversity (Burrow & Hill, 2013), and thus may prove successful in combatting age discrimination in the workplace. Therefore, the current studies sought to understand whether sense of purpose was related to ageist attitudes and hiring decisions, and how a purpose manipulation might serve as a tool to combat discrimination in hiring. Across two studies ($n = 594$, $M_{Age} = 27.20$), participants were shown the resumé of either an older adult applicant (62-years-old) or younger adult applicant (32-years-old), and were asked how hireable they would rate the applicant. The research found that the purpose manipulation did effectively increase individuals' sense of purpose. In addition, the research found that sense of purpose was negatively related to ageist attitudes. However, the purpose manipulation was unsuccessful in reducing ageist

attitudes, and had no effect on ageist discrimination in hiring. These results suggest that while sense of purpose is negatively related to ageist attitudes, manipulating purpose may not be an effective tool to reduce ageist attitudes or discrimination.

APPLYING INTERSECTIONALITY FRAMEWORK TO EXPLORE THE DEVELOPMENT OF FRAILTY IN OLDER ADULTS

Shamatree Shakya, Susan Silva, and Michael Cary, Jr.,
Duke University, Durham, North Carolina, United States

Background: Frailty is a state of compromised homeostasis reserve that makes older adults susceptible to adverse health outcomes. Frailty is highly prevalent among women, racial and ethnic minorities. We aimed to investigate the combined influence of gender, race, and ethnicity on the development of frailty in older adults without frailty at baseline using the intersectionality framework. **Methods:** The data came from the Health and Retirement Study, a nationally representative US older adults of 65 years and older (2006-2012). Logistic regressions were used to examine the relationships. **Results:** 18.7% of older adults without frailty at baseline developed frailty after a 4-year follow-up. Females were likely to develop frailty than males (aOR 1.66, 95% CI 1.32-2.09, $p < 0.0001$). In comparison to Non-Hispanic Whites, Non-Hispanic Blacks (aOR 2.66, 95% CI 1.89, 3.74, $p < .0001$) and Hispanics or others (aOR 1.73, 95% CI 1.16, 2.58, $p < .0068$) had the greater likelihood of developing frailty, after adjusting for age and clinical morbidities, such as lung disease and cardiometabolic diseases. The intersectionality approach showed that both Non-Hispanic Black females (aOR 1.82, 95% CI 1.12-2.99, $p = 0.0185$) and males (aOR 3.30, 95% CI 1.85-5.91, $p < .0001$) had the highest likelihood of developing frailty than Non-Hispanic Whites at 4-year post-baseline, adjusting for age and chronic clinical conditions. **Conclusion:** Our findings highlight the importance of taking the intersectionality approach to examining the frailty risk in later life, which will help in providing precision-based care.

ARE GENETIC AND ENVIRONMENTAL CONTRIBUTIONS TO VERBAL FLUENCY AND EPISODIC MEMORY SOLELY MODERATED BY SLEEP?

Tina Vo,¹ Shandell Pahlen,² William Kremen,³ Matthew Mc Gue,⁴ Marianne Nygaard,⁵ and Chandra Reynolds,¹ 1. *University of California Riverside, Riverside, California, United States*, 2. *University of California, University of California, California, United States*, 3. *University of California San Diego, La Jolla, California, United States*, 4. *University of Minnesota, Minneapolis, Minnesota, United States*, 5. *Department of Public Health, University of Southern Denmark, Odense, Syddanmark, Denmark*

Decreases in sleep duration and cognitive functioning often occur and co-occur in aging although these patterns are not universal. Underlying etiologies, i.e., genetic and environmental factors, contribute to why people differ on cognitive functioning at shorter versus longer sleep durations. The current study tested whether sleep duration alters the genetic and environmental contributions to why middle-aged and older adults vary on cognitive functioning. Using 4 twin studies from the Interplay of Genes and Environment Across Multiple Studies (IGEMS) consortium (Mage=56.5, range=35.0-91.2, N=5,210, 1,083 complete MZ pairs, 1,522

complete DZ pairs) we tested quantitative genetic twin models considering sleep, depressive symptoms, and age as moderators of verbal fluency (i.e., Animal Naming) and episodic memory (i.e., Word List). For verbal fluency, sleep duration and depressive symptoms were significant when dropped together from the model ($\chi^2(6)=15.22$, $p=0.02$) but not individually ($\chi^2_{\text{sleep}}(3)=7.17$, $p=0.07$; $\chi^2_{\text{dep}}(3)=5.81$, $p=0.12$), indicating that both moderators may affect differences in verbal fluency performance. For episodic memory, sleep duration moderation was only significant via the shared environmental factor ($\chi^2(1)=5.26$, $p=0.02$), indicating that sleep may affect differences in episodic memory performance via environmental influences that make siblings more similar to one another. Overall, results illustrate patterns of higher genetic influences on cognitive function at short sleep (4 hours) and higher shared environmental influences on cognitive function at long sleep (10 hours). These findings may align with associations of upregulation of neuroinflammatory processes at short sleep and common reporting of mental fatigue at long sleep, both of which are associated with poorer cognitive functioning.

ASSOCIATION OF FIRST EMPLOYMENT CHARACTERISTICS AND HOSPITALIZATION IN THE MAYO CLINIC BIOBANK

Paul Takahashi, Euijung Ryu, Nicole Larson, Gregory Jenkins, Kirt Christine, Kathleen Yost, and Janet Olson, *Mayo Clinic, Rochester, Minnesota, United States*

Work history is associated with long term health outcomes. We hypothesize that characteristics of the first work experience, such as age at first job and length of work (hereafter job) are associated with future risk of hospitalization. We further hypothesize that the length of work will be associated with hospitalization. We conducted a survey of adults >60 years using a nested case-control approach within the Mayo Clinic Biobank. We collected job related variables including age at job start, reason for ending, and length of time. To test associations between each variable and hospitalization, we used age and gender adjusted logistic regression models. Our study included 4,024 subjects: 1,801 cases and 2,223 controls. The mean age at time of match was 77.3 years (SD 7.2 years) with 49.2% males. Older age at the first full-time job was associated with lower chance of hospitalization later in life (OR=0.81 [0.67, 0.97] for those who started the job over 22 compared to those started at 18 or less). Cases were more likely to have stopped working because of illness (OR=2.04 [95% CI 1.29,3.27]). Cases were less likely to have stopped working because of retirement (OR=0.82 [95% CI: 0.72, 0.93]). We found cases were employed with a slightly shorter time (20.5 yrs. (SD 16.6)) compared to controls (21.8 yrs. (SD 16.3)) ($p=0.005$). Cases started work earlier and stopped work more frequently because of illness/disability compared to controls. This could reflect educational attainment in controls. This study highlights work history as potential predictor of future hospitalization.

ASSOCIATIONS AMONG FALL RISK APPRAISAL, BODY COMPOSITION, AND PHYSICAL ACTIVITY IN OLDER ADULTS

Ladda Thiamwong,¹ Rui Xie,² Renoa Choudhury,² Joon-Hyuk Park,² Oscar Garcia,² Aleatha Rossler,² and Jeffrey Stout,² 1. *College of Nursing, University of Central*

Florida, Orlando, Florida, United States, 2. University of Central Florida, Orlando, Florida, United States

One-third of older adults have maladaptive fall risk appraisal (FRA), a condition in which there is a discrepancy between perceived fall risk or levels of fear of falling (FOF) and physiological fall risk (balance performance). We aimed to examine the associations among FRA, body composition, and physical activity (PA) using Assistive Health Technology, including the Bioelectrical Impedance Analysis, BTrackS Balance System, and activity monitoring devices. We evaluated 124 older adults with a mean age of 74.81 (SD=7.31, range 60 to 96), 77% were female, and 72% had no history of falls. The multinomial logistic regression was used to analyze the data. FRA was classified into 4 quadrants, and we found 47% of rational FRA (low FOF and normal balance), 19% of incongruent FRA (low FOF despite poor balance), 18% of irrational FRA (high FOF despite normal balance), and 16% congruent FRA (high FOF and poor balance). We found these following variables are associated with FRA: accelerometer-based moderate to vigorous physical activity (MVPA: mins), self-reported PA score (strength & flexibility), had difficulty walking up 10 steps without resting (resistance), had difficulty walking several city blocks (ambulation), left-hand average handgrip strength, CDC fall risk score, Senior Technology Acceptance (STA) score and body composition including Body Fat Mass (BFM), Percent Body Fat (PBF), Body Mass Index (BMI), Whole Body Phase Angle, Skeletal Muscle Mass (SMM) and Skeletal Muscle Index (SMI). Our results support the efficacy of using Assistive Health Technology on screening individuals with maladaptive FRA with targeted interventions to reduce fall risk.

ASSOCIATIONS BETWEEN VISUAL, HEARING FUNCTIONING AND COGNITIVE FUNCTIONING AMONG HISPANICS/LATINOS

David Lee,¹ D. Diane Zheng,¹ Laura McClure,² Karen Cruickshanks,³ Charlotte Joslin,⁴ Hector Gonzalez,⁵ Neil Schneiderman,⁶ and Byron L Lam,¹ 1. University of Miami Miller School of Medicine, Miami, Florida, United States, 2. University of Miami Miller School of Medicine, University of Miami Miller School of Medicine, Florida, United States, 3. McPherson Eye Research Institute, University of Wisconsin-Madison, Madison, Wisconsin, United States, 4. University of Illinois at Chicago, Chicago, Illinois, United States, 5. University of California, San Diego, La Jolla, California, United States, 6. University of Miami, Miami, Florida, United States

Findings that visual impairment (VI) and hearing impairment (HI) are associated with cognitive functioning are drawn from studies that involved few Hispanic/Latino participants. We utilized data from the Miami Ocular SOL ancillary study to the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) with 1056 participants aged 45 and older. The outcomes were neurocognitive performances assessed by the Digit Symbol Substitution Test (DSST, executive function), Word Frequency Test (verbal fluency), Brief Spanish-English Verbal Learning Test-recall (B-SEVLT recall, episodic memory), and the Six-Item Screener (global cognitive functioning). Visual functioning was measured by National Eye Institute Visual Function Questionnaire (NEI-VFQ). Hearing function which was measured by Hearing

Handicap Inventory for Adults and Elderly (HHIA/HHIE) was available for all HCHS/SOL participants (n=9343). Multiple regression was performed for each cognitive outcome while controlling for age, gender, education, Hispanic/Latino ethnicity background, cardiovascular risk factors, depression and complex design. NEI-VFQ was associated with 3 of the 4 cognitive outcomes: DSST ($\beta = 0.14$, $se = 0.027$, $p < 0.01$), Word Frequency Test ($\beta = 0.042$, $se = 0.016$, $p < 0.01$), B-SEVLT-recall ($\beta = 0.021$, $se = 0.007$, $p < 0.03$). HHIA/HHIE was not associated with any of the cognitive measures examined. The HHIA/HHIE analysis was repeated using data from all sites; similar results were observed. Visual functioning but not hearing functioning is associated with worse cognition in Hispanics/Latinos, although previous HCHS/SOL analysis indicated that hearing loss as assessed by pure tone audiometry was associated with worse cognitive functioning. Longitudinal assessment of both clinical and functional measures is needed to understand the impact of sensory impairment on cognition in Hispanics/Latinos.

BETTER BRAIN HEALTH THROUGH EQUITY: ADDRESSING HEALTH AND ECONOMIC DISPARITIES IN DEMENTIA

Rajiv Ahuja, and Cara Levy, *Milken Institute, Washington, District of Columbia, United States*

Dementia disproportionately impacts the health and financial security of women and certain minority groups. Long-standing inequities create distrust of the medical system, fewer treatment options, and reduced access to care. Research predicts that from 2020 to 2060, the number of African Americans and Latinx living with dementia will grow by nearly 200 percent and 440 percent, respectively, while prevalence among non-Hispanic Whites will increase by 69 percent. As the prevalence of dementia rises, so will the costs associated with dementia care. African Americans bear 1/3 of the costs associated with dementia. And the costs for Latinx living with Alzheimer's disease are expected to exceed \$100 billion by 2060. To mitigate these growing health and economic concerns, efforts to improve dementia care must put equity front and center. This presentation highlights five actionable recommendations to build health equity by reducing disparities in dementia prevention, detection, diagnosis, and care. These recommendations center around two overarching themes: (1) Strengthening the infrastructure among health-care, long-term care, and community-based organizations to achieve greater health equity for people living with dementia and their caregivers and (2) Expanding dementia-friendly networks and workplaces in racially and ethnically diverse communities. The recommendations discussed in this presentation will offer guidance for policymakers, health services researchers, businesses, health systems, and communities to reduce the inequitable impact of dementia on African Americans and Latinx, which is even more vital amid demographic trends showing a population growing older and more racially and ethnically diverse.

BIAS AGAINST OLDER ADULTS IN YOUNG CHILDREN AND THEIR PARENTS

Jenny Jaquet (née Bauer), and Jennifer Bellingtier, *Friedrich Schiller University Jena, Jena, Thuringen, Germany*

Parents are an important source of social learning for their children. However, little is known about whether they

play a role in shaping ageist attitudes in children. We investigated how parents' biases against older adults would relate to those of their children and how preferences would differ depending on the child's age. Participants were 56 parent-child dyads with the children's age ranging from four to eight years (parents mean age = 36.95, SD = 5.49). Children were divided into three age groups, preschool (n = 18), early school-aged (n = 18), and middle school-aged (n = 20). Children and parents completed a picture rating task, which included the evaluation of 28 images of younger and older adults faces. Children used a smiley-face rating scale on a touch-screen computer, and parents used a sliding preference scale for their ratings. It was found that both, children ($t(55) = 5.47, p < .001, d = 0.73$) and their parents ($t(55) = 2.05, p = 0.045, d = 0.27$), gave significantly more positive ratings to younger than to older adults, which is consistent with an underlying bias for younger adults. Contrary to our expectations, this preference in children held across age groups and was not associated with parental preferences. Nevertheless, it has been shown that ageist preferences can already be detected in childhood. Further longitudinal research is needed to track the development of ageism from childhood on, and efforts to combat ageism should be addressed not only to adults, but to children as well.

BUTTERFLY GARDEN CONNECTS COMMUNITY LIVING CENTER RESIDENTS, FAMILY, AND STAFF DURING THE COVID-19 PANDEMIC

Maribel Rodriguez-Gonzalez,¹ Maura Miller,² Gelda Pratt,³ Micheal A Silverman,⁴ and Sandra DiScala,⁵ 1. *Florida Atlantic University- West Palm Beach VA Medical Center, West Palm Beach VA Medical Center/West Palm Beach, Florida, United States*, 2. *West Palm Beach VA Medical, West Palm Beach VA Medical Center/ West Palm Beach, Florida, United States*, 3. *West Palm Beach VA Medical Center, West Palm Beach VA Medical Center, Florida, United States*, 4. *West Palm Beach VA Medical Center, West Palm Beach VA Medical Center/ Geriatric Extended Care, Florida, United States*, 5. *West Palm Beach VA Medical Center, West Palm Beach VA Medical Center/West Palm Beach, Florida, United States*

The COVID-19 Pandemic has led to significant morbidity and mortality in older residents of long-term care facilities. In addition, the stringent restrictions on visitation of family and loved ones has further socially isolated residents leading to an increase in depression, loneliness, and spiritual distress. The Community Living Center (CLC) staff at West Palm Beach VA Medical Center wanted to address this dilemma and created a unique "Butterfly Garden" (BG) visitation space. This space is a therapeutic garden adjacent to the CLC that can be accessed by families without having to enter the facility. Participants in the BG reported feelings of peace, undisturbed reflection, and tranquility as they observed and experienced nature's life cycle. This show of nature's beauty promotes visual, tactile, and olfactory sensory stimulation while attracting hummingbirds, bees, butterflies, and peace to this calm garden space. The BG visitations offers residents, family, and staff opportunities to experience the health benefits of nature during their visits under strict CDC social contact guidelines. From September through December 2020 and from January through March 2021 there were 67 and

184 visits respectively as families became more involved. The feedback from residents, families, and staff indicated that the spirits of all participants were raised by the BG visits despite the difficult challenges of social distancing and limited CLC visitations. This BG concept could serve as a model for other long-term care facilities to allow socially distant family visits to loved ones in a safe nature-based environment of care with or without a pandemic.

CAN REMOTE MONITORING MEASURE LIFE ACTIVITY AND CAREGIVER EXPERIENCE? EARLY RESULTS OF MULTI-MODAL ASSESSMENTS

Walter Dawson,¹ Allison Lindauer,² Sarah Gothard,³ Leslie Tran,³ Zachary Beattie,³ and Jeffrey Kaye,³ 1. *Oregon Health & Science University and Global Brain Health Institute, Portland, Oregon, United States*, 2. *Oregon Health Sciences University, Portland, Oregon, United States*, 3. *Oregon Health & Science University, Portland, Oregon, United States*

Subjective assessments of dementia caregiver burden are vulnerable to recall and recency biases. Objective continuous home assessment using passive technologies (e.g., bed mats, actigraphy watches) can provide ecologically valid detail on caregiver stress and family function. We tested the utility of objective assessment of activity before, during and after the behavioral intervention of STELLA (Support via Technology: Living and Learning with Advancing AD) which facilitates effective online management of behavioral symptoms of dementia. We present preliminary data on objective measures of sleep and step counts, and subjective measures of burden. We captured data from three caregivers caring for a family member with dementia. Each family lives in home with unobtrusive monitoring devices that recorded data on sleep (Emfit sleep mat) and daily steps (Withings watch). Self-report assessments of burden, depression and grief were collected prior to and after the 2-month intervention. Objective data was collected continuously. Pre/post subjective assessments suggest that the STELLA intervention has the potential to reduce behavioral symptom frequency and caregiver reactivity to symptoms (pre-STELLA behavior frequency=44.9, post=39.2; pre-STELLA reactivity=50.5; post=38.5). Step count ranged from 775 steps/day to 5065, with each participant trending fewer steps during the intervention. Mean sleep time ranged from 6.3 to 8.6 hours and didn't change during the intervention. The small sample size limits interpretation but provides evidence that it is feasible to collect continuous objective life-activity data during caregiver interventions. This digital data has the potential to inform the validity of subjective findings by limiting recall and recency biases.

CARDIOVASCULAR MONITORING SYSTEMS FOR AGING IN PLACE: CURRENT PERSPECTIVES AND A NOVEL TOILET SEAT-BASED SYSTEM

Carla VandeWeerd,¹ Mitchell Roberts,² Lindsey Collins,³ Erica Sappington,⁴ Lydia Poon,⁴ and Jeff Lowenkron,⁵ 1. *UF Health Precision Health Research Center-The Villages, The Villages, Florida, United States*, 2. *University of Florida, Tampa, Florida, United States*, 3. *University of Florida, University of Florida, Florida, United States*, 4. *The University of Florida, The Villages, Florida, United States*, 5. *The Villages Health, The Villages, Florida, United States*

Cardiovascular disease (CVD) is a leading cause of death. Questions remain as to how older adults, providers and researchers can harness remote patient monitoring (RPM) to maintain/improve cardiovascular health--especially in light of COVID-19 and increased reliance on telehealth. The objective of this study was to understand the perceptions of older adults with cardiovascular challenges and providers surrounding a novel RPM device. The Heart Seat (THS) developed by Casana, is a toilet-seat-based cardiac monitoring device. Focus groups, stratified by gender, were conducted in 2021 by the UF Health Precision Health Research Center (UFIRB202100290) with older (55+) adults (n=36) in The Villages, Florida. Adoption, benefits/concerns, usability, utility and gender differences were explored. One-on-one provider interviews (n=6) explored future utility of THS. The primary benefit of THS noted by providers and older adults was ease-of-use and passive data collection, promoting adherence. Providers considered THS 'easy-to-use' and a positive alternative to current RPM devices. While genders' sentiments towards cardiac monitoring devices were similar, males reported having more experience with RPM. Despite this, females reported using cardiac monitoring devices more consistently than males. Therefore, passive RPM may be beneficial for increasing adherence in males. Participants' largest concern surrounding RPM was information sharing, including data monitoring, and security. Providers were also concerned about information sharing, specifically who would receive/monitor and interpret data from RPM. RPM devices should focus on enhancing ease-of-use, catering to user and provider information sharing and data monitoring/interpretation preferences and privacy.

CAREGIVING PATTERNS AND THEIR ASSOCIATION WITH CAREGIVING BURDEN AND GAINS

Talha Ali,¹ Gail McAvay,¹ Joan Monin,² and Thomas Gill,¹
 1. *Yale School of Medicine, New Haven, Connecticut, United States*, 2. *Yale School of Public Health, New Haven, Connecticut, United States*

Family and friend caregivers play a critical role in helping older adults live long and healthy lives. Using the construct of "care types" we examine whether caregivers providing more intense care experience higher burden and lower gain compared to caregivers providing less intense care. Data are from the 2015 and 2017 rounds of the National Study of Caregiving (N=2,146), a study of the caregivers of older adults enrolled in the National Health and Aging Trends Study. In a previous analysis, we derived five care types at baseline (2015), that varied in the number and type of care activities, care duration, and regularity of care provided. Caregivers reported whether caregiving was financially, emotionally, and physically difficult for them. Participants were also asked whether caregiving made them more confident, taught them to deal with difficult situations, brought them closer to the recipient, and gave them satisfaction that the recipient was well cared for. We estimated the association between care types derived at baseline and caregiver burden and gains at follow-up using logistic regression. Compared to caregivers in the least intense care type, those in the more intense care types were significantly more likely to report financial and physical burden, as well as increased ability to deal with difficult situations and increased satisfaction

that their loved one was well cared for. These associations remained significant after adjusting for confounders. Care types can be used to predict burdens and gains experienced by caregivers and to effectively target caregiver support services and interventions.

CHANGES IN DAILY LIFE CONDITIONS AMONG KOREAN OLDER ADULTS AFTER COVID-19 OUTBREAK

Jiyoung Lyu, Young Bum Kim, and Yeon Ok Lim, *Hallym University, Chuncheon, Kangwon-do, Republic of Korea*

The pandemic of COVID-19 has had a significant impact on peoples' daily life conditions. Therefore, it is worth understanding changes in daily life conditions among older adults after COVID-19 outbreak. This study was aimed to explore the impact of the pandemic on daily life conditions among Korean older adults. To achieve this aim, an online survey was conducted during April, 2021 to include 184 Korean adults aged 60 years or older nationwide. The results are as follows. First, about 54.9% older Koreans reported that their daily life has stopped since COVID-19. Second, the top 3 increased daily life conditions were spending time at home (77.2%), using internet (60.3%), and shopping online (51.6%). Third, the top 3 decreased daily life conditions were traveling (90.2%), meeting with friends (90.2%), and meeting with family members (80.4%). Fourth, the top 3 daily life conditions with no change were sleeping time (72.3%), eating instant food (58.2%), and household income (53.8%). These findings suggest that several daily life conditions changed after COVID-19 outbreak. Further study is needed to examine the impact of these changes on physical and mental health among older adults.

CHILD MALTREATMENT AND THE PSYCHOLOGICAL CONSEQUENCES OF COVID-19 FOR OLDER ADULTS

Tyler Bruefach, Dawn Carr, and Natalie Sachs-Ericsson, *Florida State University, Tallahassee, Florida, United States*

Traumatic experiences in early life impact adults' well-being and their abilities to respond to adversities over the life course. Child maltreatment is a particularly salient stressor in childhood and scholars have noted the psychological implications of such experiences that extend into late life. People who experienced maltreatment in childhood have more difficulty maintaining and developing high quality relationships, regulating their emotions, and they engage in poorer coping behaviors amidst major stressors. Our study focuses on how child maltreatment (i.e., emotional abuse; physical abuse; sexual abuse; emotional neglect) shaped older adults' changes in depression during the early stages of the COVID-19 Pandemic. Using a dataset released in 2021, based on a community sample of older adults collected in September 2018 and June 2020, we found that exposures to emotional neglect (1.630; $p < 0.001$) and emotional abuse (0.670; $p < 0.05$) in childhood were both associated with increases in depression scores in association with the pandemic, relative to those without such exposures. In addition, the more forms of maltreatment that individuals were exposed to in childhood, the more they experienced negative psychological health consequences in association with the pandemic. Our results suggest that early life traumas play a role in how older adults respond to stressful situations.

Clinical treatments for depression may be more effective if they take into consideration how these early life experiences influence exposures to new stressors in later life.

CO-DESIGNING A VIRTUAL REALITY APPLICATION TO ENHANCE REMINISCENCE THERAPY FOR PERSONS WITH DEMENTIA

Winnie Sun, and Alvaro Quevedo, *Ontario Tech University, Oshawa, Ontario, Canada*

Reminiscence therapy for persons with dementia is often being conducted by employing analog media including pictures and videos organized and presented by a caregiver. However, such media lacks the immersive experience to support patient engagement and successful recollection of reminiscence events. Recently, Virtual Reality (VR) is gaining momentum as a potential technological tool to support dementia care due to its increased immersion, presence, and embodiment. Haptic artifacts can be used to enrich reminiscence therapy as part of the multi-sensory stimuli to increase immersion and patient engagement, as well as improving social connectedness and cognitive health. The purpose of this project is to explore the use of VR application to advance reminiscence therapy for persons with dementia. We have prototyped an immersive and non-immersive VR framework that allows caregivers to deliver reminiscence therapy for persons with dementia with varying stages in their disease progression. These reminiscence therapy sessions are built by employing a narrative storyboard and content management through a series of co-designing sessions with content experts at the Geriatric Dementia Unit in Ontario, Canada. A caregiver-led VR framework will be adopted to enable the caregiver to guide the persons with dementia to safely navigate through the interactive VR environment, while allowing the patients to engage with the interactive VR elements using a point-and-pinch gesture approach. We anticipate that the VR experiences hold the potential for improving the interactions between persons with dementia and caregivers, as well as enhancing the reminiscence experiences to promote the maximal therapeutic benefit of patient's recovery.

COLLECTION OF FREE-LIVING ACCELEROMETRY DATA IN LARGE CLINICAL STUDIES BEFORE AND DURING THE COVID-19 PANDEMIC

Jacek Urbanek,¹ Kunihiro Matsushita,² Robert Kaplan,³ Josef Coresh,² and Jennifer Schrack,² *1. Johns Hopkins School of Medicine, Baltimore, Maryland, United States, 2. Johns Hopkins University, Baltimore, Maryland, United States, 3. Albert Einstein College of Medicine, New York, New York, United States*

The recent COVID-19 pandemic had a substantial impact on clinical research, including recruitment and follow-up visits in new and ongoing studies, especially affecting ones focused on older, at-risk adults. As the objective assessment of physical activity with wearables is usually initiated during in-person visits, the collection of these data experienced substantial, unplanned gaps. We report the frequency of data collection (visits-per-month) in studies collaborating with the Accelerometry Resource Core (ARC) at Johns Hopkins Center on Aging and Health. We focus on two, NIH-funded, studies that implemented the ARC accelerometry protocol. The Atherosclerosis Risk in Communities that stopped visit

8 enrollment in early 2020 and reinstated in 2021 for visit 9, and the Peripheral Artery Disease Study of SOL that started the data collection in early 2021, first via the mail-in protocol, then shifting towards in-clinic visits. Through March 2020, ARC processed an average of 125 new accelerometry per month (SD = 54). There was no new data collected for the remainder of 2020. The collection restarted in January 2021 with an average of 55 (SD = 43) files a month in the first and 112 (SD = 53) in the second quarter of 2021. A total of 573 new accelerometry observations were collected across both studies since the first wave of COVID-19 in March 2020 including 282 observations collected exclusively using a mail-in protocol. This recovery of data collection demonstrates that wearable devices allow for safer, remote assessment of physical activity, function, and sleep eliminating the need for in-person visits.

COMMUNICATION DIFFICULTIES AND THEIR ASSOCIATION WITH CAREGIVING BURDENS IN APHASIC DEMENTIA

Angela Roberts,¹ Haylie Santos,¹ Nathan Gill,² Hui Zhang,² Elizabeth Salley,² and Emily Rogalski,² *1. Northwestern University, Evanston, Illinois, United States, 2. Northwestern University, Chicago, Illinois, United States*

Primary progressive aphasia (PPA) is a clinical dementia syndrome for which there is no effective disease-modifying treatment. Impairments in language are the primary and persistent symptoms, and severely limit participation in everyday activities and family conversations. Despite this, there are no published studies examining the objective relationship between conversation difficulties and caregiving burden in PPA. We tested the hypothesis that the severity of care partner perceived conversation difficulties predicts caregiving burden using the Perception of Conversation Difficulty-Dementia Alzheimer's Type and the Montgomery Borgatta Caregiving Burden Scale. The analysis included baseline data from 78 care partners (62% female) enrolled in the Communication BridgeTM-2 randomized control clinical trial of a speech-language intervention for PPA. Care partners had a mean age of 64.5 years (SD=10.76) and a mean relationship duration with the PPA participant of 38.6 years (SD=15.29). Eighty-six percent were spouses, 5% were adult children, and the remaining 9% were friends or siblings. Higher ratings of conversation difficulties were associated with increased caregiving burden for both objective burden ($p < 0.001$) and subjective stress burden ($p < 0.001$). The relationship between conversation difficulties and objective burden was mediated by dependence in activities of daily living and care partner depression, whereas the relationship with subjective stress burden was mediated by depression only. This is the first large scale study of care partner reported conversation difficulties and caregiving burden in PPA. The finding that conversation difficulties have a direct relationship with caregiving burden is an important consideration for interventions and outcome measurement in PPA.

CONCURRENT AND PREDICTIVE ASSOCIATIONS BETWEEN THE LIFE'S SIMPLE 7 & BRAIN STRUCTURE IN MIDDLE-AGE AND EARLY-OLD AGE

Teresa Warren,¹ McKenna Williams,² Christine Fennema-Notestine,² Jeremy Elman,²

Jennifer De Anda,¹ William Kremen,² and Carol Franz,²
 1. *San Diego State University, San Diego, California, United States*, 2. *University of California San Diego, La Jolla, California, United States*

American Heart Association's (AHA) Life's Simple 7 (LS7), an index of cardiovascular health risks, has been associated with worse brain outcomes but few examined this relationship in midlife. We examined whether LS7 scores at midlife were associated with brain morphometry in early old age. Participants were 471 men who participated in the Vietnam Era Twin Study of Aging. The LS7 index was assessed at mean age 62 (range 55-66) and 68 (range 61-71) and included smoking, physical activity, diet, body mass index, cholesterol, glucose, and blood pressure. Each factor was coded, per AHA criteria, on a 3-point scale (0/poor-2/ideal) and summed to create a composite score (0-14). At mean age 68, participants underwent structural magnetic resonance imaging, which was used to create the previously validated brain measures. Scores included: the ratio of abnormal white matter to white matter, and two Alzheimer's disease brain signatures (cortical thickness/volume signature and a mean diffusivity (MD) signature). Analyses controlled for age, education, income, ethnicity, and APOE genotype. Concurrently at mean age 68, the LS7 was associated with cortical thickness/volume ($F=4.85$, $p = .028$), MD ($F=10.89$, $p = .001$) signatures and abnormal white matter ratio ($F=14.04$, $p < .001$). Prospectively, the LS7 at mean 62 was significantly associated with age 68 cortical thickness/volume ($F=5.08$, $p = .025$) and MD ($F=5.54$, $p = .019$) signatures but not with abnormal white matter ratio. These results suggest that prevention strategies that promote heart healthy behaviors could have implications for healthy brain aging.

CONSEQUENCES OF GENOMIC DNA MONO-RIBONUCLEOTIDES FOR CHROMOSOMAL STABILITY

Tavia Roache, *Howard University, Washington, District of Columbia, United States*

Mono-ribonucleotides are building blocks for polynucleotide RNA chains (e.g., messenger RNA), but if misincorporated into duplex DNA can cause mutagenesis and chromosomal instability. During DNA synthesis by Pol γ , remnants of unremoved RNA primers contribute to elevated mono-ribonucleotide triphosphates resulting in nucleotide pool imbalance, ultimately favoring mis-incorporated ribonucleotides during replication. Moreover, although polymerases generally replicate DNA with high fidelity, the steric gate occasionally allows a mis-incorporated ribonucleotide. Thus, a mono-ribonucleotide is one of the most abundant lesions in genomic DNA of eukaryotes. If unremoved from double-stranded DNA, the ribonucleotide exerts negative effects on replication, transcription, and genomic maintenance, with lasting effects on cellular homeostasis. Even a single ribonucleotide in telomeric DNA comprises shelterin binding and telomere capping causing vulnerability to spontaneous hydrolysis which potentiates telomere shortening. Consistent with this, a ribonucleotide positioned in double-helical DNA alters its structure by torsionally distorting the sugar-phosphate backbone. Fortunately, cellular response and repair pathways exist to help cells cope with mis-incorporated mono-ribonucleotides. The Ribonucleotide Excision Repair

(RER) or a Topoisomerase 1 (Top1)-mediated pathway remove embedded ribonucleotides. For RER, RNase H2 incises 5' of a mono-ribonucleotide, creating an access point for its removal. If cells are deficient in RNase H2, Top1 initiates removal of the ribonucleotide. However, Top1 is less accurate than RNase H2, which can lead to mutagenesis. Studying the mechanisms in which ribonucleotides are incorporated into DNA or further metabolized should provide insight to their negative consequences for chromosomal integrity, cancer, and auto-immune disease attributed to a genetic deficiency of RNase H2.

CONSEQUENTIAL IMPACTS OF TOBACCO USE ON COGNITIVE PERFORMANCE

Shandell Pahlen,¹ Michael Stallings,² Robin Corley,³ Sally Wadsworth,³ and Chandra Reynolds,⁴ 1. *University of California, University of California, California, United States*, 2. *University of Colorado, Boulder, Boulder, Colorado, United States*, 3. *University of Colorado Boulder, Boulder, Colorado, United States*, 4. *University of California Riverside, Riverside, California, United States*

Tobacco use represents a pernicious lifestyle factor that may influence processes of aging, including cognitive functioning. As individuals tend to start smoking before adulthood, it may serve as an important factor in cognitive development and maintenance. We explored smoking history-cognition associations in a sample approaching midlife. Study data was derived from the Colorado Adoption/Twin Study of Lifespan behavioral development and cognitive aging (CATSLife 1; $N = 1195$ [53% F]; \bar{x} age = 33.2 years, $SD = 5.0$). All cognitive measures were t-scored covering working memory, spatial reasoning, processing speed (WAIS-III Digit Span, Block Design, and Digit Symbol, and Colorado Perceptual Speed) and episodic memory domains (Picture Memory, immediate and delayed). Tobacco use measures included ever-smokers, current-smokers, and log-transformed packyears. Mixed-effects regression models were applied, accounting for sex, age, race, ethnicity, and clustering among siblings. Tobacco use was associated with worse episodic memory, spatial and speed performance, but not working memory. When educational attainment was included, patterns remained consistent though attenuated. Results suggested current-smokers scored 0.27 to 0.36 SD lower than non-smokers on speed and spatial reasoning tasks. Episodic memory performance was reduced by approximately 0.07 to 0.1 SD per log packyear. In a sample approaching midlife, the harmful impacts of tobacco use on cognitive performance may be already apparent with cumulative impacts of packyears on episodic memory and current smoking associated with spatial and speed performance. This work helps to elucidate the temporal associations of an important lifestyle factor that may influence cognitive functioning prior to midlife.

COVID-19 RELATED MEDIA CONSUMPTION AND MENTAL HEALTH IN OLDER ADULTS

Erta Cenko,¹ Christopher Kaufmann,² and Todd Manini,¹
 1. *University of Florida, Gainesville, Florida, United States*, 2. *University of Florida*

At the beginning of the COVID-19 pandemic, consuming media was critical to identify precautionary behaviors to reduce the spread of the virus, particularly for older adults.

Media consumption leads to heightened awareness, but may also negatively affect mental health. We examined whether non-social and social media consumption impacted anxiety and depression relative to pre-COVID-19 symptoms. We conducted an anonymous, cross-sectional survey in May and June 2020. Participants ($n=1,168$, 73.2 years, 56.8% women, 94.9% White), were asked to estimate their amount of time spent consuming pandemic-related media each day, and to report on anxiety and depressive symptoms both before and after the pandemic onset. We characterized change in anxiety and depression by subtracting scores on current anxiety and depressive symptoms from their recalled symptoms prior to the pandemic. Respondents with high pandemic-related media consumption (>3hrs) were more likely to have increased anxiety, compared to those with low (<1hr) media consumption (OR:1.57, 95%CI:1.09-2.23). Similarly, respondents with increased social media consumption during the pandemic were 64% more likely to have depression, compared to those who did not use social media. This association was bi-directional—those who reduced their social media use were 45% less likely to have depression and 26% less likely to have anxiety, compared to those who never used social media. Older adults consuming more pandemic-related media had increased anxiety. Increased social media consumption was associated with elevated depression symptoms. The potential benefits of media consumption about the COVID-19 pandemic may have unintended negative consequences on mental health.

COVID-19 TELECONFERENCING EXPERIENCES OF CAREGIVERS & SPOUSES WITH DEMENTIA FROM QA/QI SUPPORT GROUP STUDY

Roscoe Nicholson,¹ Mary Mittelman,² Maureen O'Connor,³ Andrew Nguyen,⁴ Rebecca Salant,⁵ Tiffany Donley,⁶ Cynthia Epstein-Smith,⁷ and Steven Shirk,⁸ 1. *University of Chicago, Evanston, Illinois, United States*, 2. *NYU Langone Health NYU Grossman School of Medicine, NYU Grossman School of Medicine, New York, United States*, 3. *VA Bedford Healthcare System, Bedford, Massachusetts, United States*, 4. *Boston University School of Medicine, Boston, Massachusetts, United States*, 5. *NYU School of Medicine, NYU School of Medicine New York City, New York, United States*, 6. *NYU School of Medicine, New York, New York, United States*, 7. *NYU Langone Health, New York, New York, United States*, 8. *Bedford Veterans Administration Medical Center, Bedford, Massachusetts, United States*

In summer 2020, researchers conducted a Quality Assurance and Quality Improvement (QA/QI) assessment of the NYU Langone Alzheimer's Disease and Related Dementias Family Support Program's adaptations in response to COVID by interviewing 10 participating spouse caregivers of persons with dementia (PWD). The primary adaptations were shifting from in-person to online services, changing support groups from biweekly to weekly, and offering an arts-based group for PWD daily rather than weekly. In the course of these interviews, all respondents described their adaptation to remote teleconferencing programming, and five also contrasted their experiences with those of the PWD. Methods: After transcription and de-identification, a codebook was created from the transcript content that

included a priori topics of interest as well as emergent themes using framework analysis. These transcripts were then coded by two independent coders through an iterative process and consultation with the codebook creator, who also resolved any discrepancies between coders. Results: Respondents reported largely successful transitions to teleconferencing for themselves, though missing the physical contact afforded by meeting in-person. However, they also described some interactional challenges related to participants talking over one another, and suggested more active moderating to facilitate greater turn-taking. The respondents' descriptions of the PWD's response suggested a much less successful transition to teleconferencing. Challenges and barriers included lack of interest, difficulty following or participating in conversation, and teleconferencing creating confusion, such making it "hard for her to separate out when everybody's in the same place or not."

CREATION OF A LATIN-AMERICAN DEMENTIA ADVANCE CARE PLANNING GUIDE

Moroni Fernandez Cajavilca,¹ Lauren Solkowski,² Rebecca Utz,³ Ana Sanchez-Birkhead,² Nancy Aruscavage,³ Katherine Supiano,² Eli Iacob,³ and Kara Dassel,³ 1. *University of Utah Hospital, West Valley City, Utah, United States*, 2. *University of Utah, University of Utah, Utah, United States*, 3. *University of Utah, Salt Lake City, Utah, United States*

The LEAD Guide (Life-Planning in Early Alzheimer's and Dementia) is an advance care planning conversation guide for use within the context of dementia (Dassel et al., 2019). Considering that Latino adults have the highest risk of ADRD, a culturally sensitive and translated Spanish version of the LEAD Guide was needed. Therefore, the objective of this study was to: 1) translate the LEAD Guide into a Latin-American Spanish version (i.e., LA LEAD) and 2) assess the applicability and acceptability of the LA LEAD through focus groups with Latino older adults. First, the LEAD Guide was translated into a "neutral" Spanish version. Second, forward and backward translation was conducted to create the LA LEAD. Third, two 1.5-hour focus groups with Spanish-speaking Latino adults age 50+ who were: a) healthy adults ($N=7$) or b) current or previous dementia caregivers ($N=7$) were held. The focus groups were recorded, translated, and transcribed for descriptive analysis, which revealed three domains regarding the LA LEAD: 1) Family Dynamics: the guide could help prevent family conflict, designate a health care proxy, and reduce burden; 2) Cultural Expectations: acknowledgement of cultural nuances between LA countries, the familial responsibility of caring for family in the home, and the influence of religion on end-of-life care decisions, and 3) Health Literacy: lack of knowledge about advance care planning conversations, documentation, and dissemination. This process resulted in the creation of a validated LA LEAD Guide, which is a culturally and linguistically appropriate and acceptable advance care planning tool for Latino older adults.

DEMENTIA-RELATED CARE IN ACUTE CARE SETTINGS: A QUALITATIVE META-SYNTHESIS OF PATIENT AND FAMILY PERSPECTIVES

Richard Chunga, *University of Massachusetts Boston, Kew Gardens, New York, United States*

Researchers have long emphasized the importance of a person-centered approach to health care, especially regarding the treatment of individuals living with dementia. However, the fast pace of acute care settings can be a difficult place to provide such care to patients, where there are tensions between the emphasis on efficient treatment of acute medical co-morbidities and person-centered dementia care. This paper is a meta-synthesis of qualitative studies examining perspectives of patients and their family members regarding their acute care experiences. It takes an interpretive approach, using primarily inductive reasoning to generate themes across available studies' findings. Emergent themes are organized under two major dimensions of the hospital environment: the physical environment, including sensory and tangible elements, and the social environment, including the hospital atmosphere and communication practices. Persons with dementia feel overly stimulated by the busy physical environment of the hospital, yet they are often left to languish alone, sometimes even physically restrained. Patients reported feeling lonely, fearful, and confused, identifying diverse physical and social environmental attributes like physical clutter, noise, and lack of empathy from care providers as contributors. Based on acute care experiences and reports from patients and family members, although the acute condition is treated, persons with dementia often leave the acute care environment in worse functional condition than when they entered. Given the increasing prevalence of persons with dementia in acute care settings, it is clear that we must prioritize innovations and programs aimed at improving hospital practices, educating staff, and creating more dementia-friendly environmental designs.

DEVELOPING BEHAVIORAL MARKERS OF SOCIAL FUNCTION IN AGING: A METHODOLOGY USING PITCH MIMICRY

Christine Williams,¹ Emmanuelle Tognoli,¹ Alice Wead,² Christopher Beetle,¹ and Joseph McKinley,¹ 1. *Florida Atlantic University, Boca Raton, Florida, United States*, 2. *Florida Atlantic University, BOCA RATON, Florida, United States*

The Covid pandemic brought to the forefront the crucial role of social interactions for society at large and in gerontological practice. Social interactions play a paramount role in preserving cognitive reserve in older adults. They rely on neurobehavioral processes that are complex (engage large parts of the brain and demand integrity of multiple perceptuomotor, attentional, cognitive and memory functions). Pitch mimicry is a well-known and spontaneously arising social phenomenon that requires the integrity of numerous processes of the brain, and we hypothesize that it constitutes a potentially sensitive behavioral marker of neurodegeneration in Alzheimer's Disease and Related Dementias (ADRD). We developed and validated a series of algorithms to parse verbal exchanges between people and quantify the level of mimicry that each exhibit with their partners. Those algorithms are based on silence thresholding, carefully parametrized CEPSTRAL algorithms for automatic pitch estimation and Synchrosqueezing Transform for validation. We introduce a theoretical model to compare our estimates of pitch mimicry with model's expectations based on the null hypothesis that its neurobehavioral pathways

retain their integrity. Our method will allow researchers to study the evolution of pitch mimicry in aging individuals and its sensitivity to diverse social contexts, including those preserving lasting social engagement. Our method will also allow us to test the hypothesis that Pitch Mimicry is a sensitive behavioral marker of dementia, a condition characterized by a breakdown in social relatedness.

DEVELOPMENTAL ANALYSIS OF PROSPECTIVE EFFECTS OF PROBLEM DRINKING AND HEALTH PROBLEMS IN THREE-AGE GROUPS

Thomas Kwan,¹ Douglas Bowlby,² and Matthew Lee,³ 1. *Rutgers University, Manalapan, New Jersey, United States*, 2. *Rutgers University, Rutgers University, New Jersey, United States*, 3. *Rutgers University, Piscataway, New Jersey, United States*

Past research has clearly demonstrated interrelations between drinking and health. However, little research has investigated this from a lifespan-development perspective, which is the objective of the current study. Our hypotheses predicted results consistent with the familiar "J-shaped curve" of drinking effects on health, including that health problems would be (1) lower in moderate drinkers than abstainers and (2) higher in excessive drinkers than moderate drinkers. We also hypothesized that these protective effects of moderate drinking would increase with age across the lifespan. The current study used two waves of data from a large U.S.-representative sample. Analyses used 3*3 between-persons ANCOVAs that tested a three-level Wave-1 drinking-group factor and a three-level Wave-1 age-group factor. Of particular importance were the drinking-group-by-age interactions. Various Wave-2 health outcomes were predicted in different ANCOVAs, and each ANCOVA controlled for Wave-1 levels of the Wave-2 health outcome. Across nearly all health outcomes, young adults did not show significant differences between abstainers and moderate drinkers, whereas midlife and older adults consistently showed better health for moderate drinking versus abstainers. This suggests that protective effects of moderate drinking apply more-so to midlife and older adults than young adults. Surprisingly, excessive drinkers generally did not show poorer health than moderate drinkers, except for mixed evidence for such effects only among older adults. Thus, only older adults showed patterns entirely consistent with our hypothesized "J-shaped curve." A next analytic step we will conduct in advance of this poster presentation will assess if alternative excessive-drinking operationalizations more consistently signal health problems.

DIETARY PATTERNS OF US CHINESE OLDER ADULTS

Alexander Dong,¹ Lisa Lanza,² Qun Le,¹ Stephanie Bergren,¹ and Dana Dychtwald,¹ 1. *Rutgers University, New Brunswick, New Jersey, United States*, 2. *Rutgers University, Rutgers Institute for Health, New Jersey, United States*

A westernized diet, characterized by intake of foods high in fat and sugar, has been associated with several chronic conditions. However, the dietary pattern of US Chinese older adults is not well understood. The primary objective of this study was to determine the relationship between years of US residence and other demographic factors and the intake of foods high in fats and sugar. As part of the Population Study

of Chinese Elderly, participants were given a 48-item food frequency questionnaire, which were further placed into primary food groups. Each group was then categorized into whether they consumed the food group at least once a week. The total sample was 59% female with an average age of 75, with 49% consuming fatty foods and 85% consuming sweets in the past week. Using logistic regression (N=3053), each additional year of US residence (range of 0-93 years) was associated with a higher dietary intake of fats (OR: 1.01 (95%CI:1.01-1.02)) and sweets (OR: 1.01 (95%CI:1.00-1.02)). Additionally, higher education was associated with lower consumption of fats (OR: 0.98 (95%CI:0.96, 0.99)) and higher income was associated with higher consumption of fats (OR: 1.11 (95%CI: 1.04, 1.18)). For sweets, women compared to men were 54% less likely to consume sweets in the last week (OR: 0.46 (95%CI:0.36, 0.59)), and higher education was associated a greater likelihood of consuming sweets (OR: 1.07 (95%CI: 1.05, 1.10)). Study findings suggest that immigration related factors and demographic factors may influence consumption of a westernized diet high in fats and sugars.

DISCRIMINATION AND SLEEP IN CHINESE AMERICAN OLDER ADULTS

Alexander Dong,¹ Stephanie Bergren,¹ Qun Le,¹ Lisa Lanza,² and Dana K. Dychtward,¹ 1. *Rutgers University, New Brunswick, New Jersey, United States*, 2. *Rutgers University, Rutgers Institute for Health, New Jersey, United States*

Since the start of COVID-19, reports of discrimination in the US against Asian Americans have increased approximately 150%. Prior research has demonstrated that victims of discrimination are more likely to experience physiological health concerns, possibly linked to sleep. The objective of this study was to determine if there was a relationship between disordered sleep and discrimination among Chinese older adults using data collected from the Population Study of CHINESE Elderly (N=3124, 59% female). To assess, the experience of discrimination in nine settings (school, hiring, work, housing, medical, service, finance, public, and authority) and four indicators of sleep quality (duration, trouble falling asleep, insomnia, and self-reported sleep quality) were evaluated using logistic- and multinomial logistic regression. With an average age of 75 years, discrimination was experienced by 7.2% of participants. Experiencing any discrimination was associated with lower odds of longer sleep durations (>8 hours) compared to those sleeping 6-8 hours. Experiences of discrimination in housing (OR: 5.51 (95%CI:1.08-27.98)) and with authority figures (OR: 6.02 (95%CI:1.16-31.31)) were significantly associated with shorter sleep durations (<6 hours), compared to those sleeping 6-8 hours. Those who experienced discrimination in a school setting were less likely to have trouble falling asleep (OR: 0.28 (95%CI:0.09-0.88)), while discrimination in medical settings were more likely to experience insomnia (OR: 2.29 (95%CI:1.13-4.63)). All other relationships between discrimination and sleep measures were non-significant. Given mixed evidence and the increased relevancy of discrimination against Asian Americans, further research on how discrimination may impact health outcomes and sleep quality is warranted.

DRAG EXPRESSION AMONG OLDER GAY MEN: EXPLORATORY FINDINGS OF A PILOT STUDY

Brian Chapman,¹ Laura Donorfio,¹ and Debra Tomasino,² 1. *University of Connecticut, Waterbury, Connecticut, United States*, 2. *UConn, Mansfield, Connecticut, United States*

This poster presentation highlights pilot findings of how older gay male drag queens define drag expression and its associated positive and negative attributes. While drag has become more mainstream, little is known about this sexual and gender minority (SGM) and what it means to be an older drag queen and how it interfaces with societal gender expectations. (Knutson, Koch, Sneed, Lee, & Chung, 2020; O'Brien, 2018). Research to date reports that while sexual minority youth experience bullying, anxiety, lower self-esteem, and suicidal ideation at higher rates than their heterosexual and gender conforming peers, research has not examined the role drag expression plays as a healthy coping mechanism and, in particular, what role it may play for older drag queens. (Levasseur, Kelvin, Roskopf, 2013; Mueller, James, Abrutyn, & Levin, 2015). Several studies have found that familial support and connectedness offers valuable protective factors for sexual minority youth in their sexual identity development, but again, little is known about the benefits this may provide older drag queens (Brandon-Friedman & Kim, 2016; Eisenberg & Resnick, 2006). Utilizing Grounded Theory, in-depth interviews were conducted with gay males over the age of fifty (n=5) who identified as drag queens to understand how drag expression is integrated into one's persona, how it may serve as a healthy coping mechanism, and how it interfaces with dragism, generativity, and family relationships over their lifespan (Donorfio, 2020). In addition to sharing the qualitative findings, demographic and data measures of personality, coping, resilience, and mood are also reported.

EARLY CLINICAL UTILITY DATA OF A BLOOD BIOMARKER TEST IN THE EVALUATION OF MILD COGNITIVE IMPAIRMENT

Mark Monane,¹ Joy Snider,² Jonathan Drake,³ Tim West,⁴ Ilana Fogelman,⁵ Joel Braunstein,⁵ David Holtzman,² and Randall Bateman,² 1. *Monane Group Clinical Consulting, Woodcliff Lake, New Jersey, United States*, 2. *Washington University, Washington University, Missouri, United States*, 3. *The Warren Alpert Medical School of Brown University, The Warren Alpert Medical School of Brown University, Rhode Island, United States*, 4. *C2N, St. Louis, Missouri, United States*, 5. *C2N Diagnostics, St. Louis, Missouri, United States*

There is an important unmet need for timely, noninvasive, low-burden evaluation of patients presenting with mild cognitive impairment (MCI). The PrecivityAD™ blood test quantifies plasma concentrations of amyloid- β 42 and 40 and apolipoprotein E-specific peptides that are combined with age in an algorithm to identify the likelihood of amyloid plaques in the brain as measured by amyloid PET scans. This test has previously demonstrated 92% sensitivity and 77% specificity. The study objective was to evaluate the clinical utility of the test and the Amyloid Probability Score (APS), the test output value. Eighteen patients (median age 72, 55% male,

88% white) with MCI received the PrecivityAD blood-based biomarker test. The mean APS was 31 (range 0-91): 13 patients had low scores (APS 0-35), 2 had high scores (58-100) and 3 had intermediate (inconclusive) scores (APS 36-57). The mean probability of Alzheimer's disease (AD) diagnosis was rated by clinicians as 63% (range 25-80) pre-test and 31% post-test (range 5-95) ($p < 0.0005$). AD probability rated by clinicians was decreased in 12/13 low APS patients and increased in 2/2 high APS patients. Donepezil was discontinued in 5/8 low APS patients on therapy and initiated in 1/1 high APS patients not on therapy, representing a change in treatment management in 33% (6/18) of study patients. In summary, this blood-based biomarker test showed clinical utility in its association with physician decision-making around diagnostic certainty and drug therapy management in MCI patients.

EFFECTIVENESS OF HOME- AND COMMUNITY-BASED SERVICES IN DECREASING HEALTH CARE SERVICE AND EXPENDITURE IN TAIWAN

Ya-Mei Chen,¹ Shih-Cyuan Wu,¹ Shiau-Fang Chao,² Kuan-Ming Chen,³ Chen-Wei Hsiang,⁴ Ming-Jen Lin,¹ Ji-Lung Hsieh,⁵ and Kuan-Ju Tseng,⁴ 1. *National Taiwan University, Taipei, Taipei, Taiwan (Republic of China)*, 2. *National Taiwan University, Taipei City, Taiwan (Republic of China)*, 3. *National Bureau of Economic Research, CAMBRIDGE, Massachusetts, United States*, 4. *National Taiwan University, National Taiwan University, Taipei, Taiwan (Republic of China)*, 5. *Graduate Institute of Journalism, Taipei City, Taipei, Taiwan (Republic of China)*

Background Whether long-term care service use decreases older adults' health care service use and cost has been a strong interest among aging countries, including Taiwan. The current study examined the impact of continuous use of HCBS offered by Taiwan's LTC plan 2.0 on older adults' health service utilization and cost overtime. **Methods** This study used the LTC Plan 2.0 database and the National Health Insurance Plan claim dataset, and included 151,548 clients who had applied for and were evaluated for LTC services for the first time from 2017 through 2019 and continuously used any LTC Plan 2.0 services for six months. Outcome variables were users' health service utilization and health care cost 12 months before and after starting to continuously use HCBS. Latent class analysis and generalized estimating equations were used to investigate the influences of different service use patterns on the changes in physical functions. **Results** Three subgroups of LTC recipients with different use patterns, including home-based personal care (home-based PC) services ($n = 107324$, 70.8%), professional care services ($n = 30466$, 20.1%), and community care services ($n = 13794$, 9.1%) were identified. When compared to care recipients in the community care group, those in the home-based PC group had more emergency room expenditures (1 point/month, $p < 0.05$) but less hospitalization expenditures (38 points/month, $p < 0.001$), while the professional care group had less emergency room and hospitalization expenditures (3 and 138 points/month, $p < 0.001$). **Conclusion** Those receiving professional care and home care services spent less on health care service utilization.

EFFECTS OF GLYCINE SUPPLEMENTATION ON MITOCHONDRIAL FUNCTION AND PROTEIN DEGRADATION IN SKELETAL MUSCLE OF OLD MICE

Giulia Lizzo,¹ Kamila Muller,¹ Jonathan Thevenet,¹ Stefan Christen,¹ Kim Zarse,² Michael Ristow,² Nabil Bosco,¹ and Philipp Gut,³ 1. *Nestlé Research, Lausanne, Vaud, Switzerland*, 2. *ETHZ, Zurich, Zurich, Switzerland*, 3. *Cell Biology, Nestlé Institute of Health Sciences, Nestlé Research, Lausanne, Vaud, Switzerland*

Glycine is the simplest amino acid and it has a pivotal role in different metabolic processes, such as being a building block of glutathione, collagen and purine bases, or taking part in methylation reactions, detoxication and ammonia metabolism. Although considered for many years a non-essential amino acid, glycine levels are decreased in certain conditions, as the endogenous synthesis cannot fulfill the needs required to sustain all the cellular processes in which glycine is involved. Here we describe that glycine levels are significantly lower in skeletal muscle of aged zebrafish and mice and in plasma of humans compared to young subjects. We therefore fed healthy old mice for 6 weeks with a glycine-supplemented diet and observed a significant restoration of glycine levels in skeletal muscle and liver towards young mouse levels. Moreover, old mice showed decreased mitochondrial function in glycolytic and oxidative fibers, and a significant increase in oxygen consumption was observed in glycolytic fibers after glycine supplementation. The improvement of mitochondrial function is not associated to an increased mitochondrial biogenesis or an increased antioxidant capacity, but glycine supplementation increases both total GSH and GSSG levels, suggestive of a pro-oxidant environment. Overall, glycine supplementation induced an increase in the cross-sectional area of fibers. Finally, we carried out RNA-Seq study to decipher the impact of higher glycine intake. Our results suggest that age-associated glycine deficiency plays an important role in atrophy of muscle, especially in glycolytic fibers, and is reversible with a dietary supplementation.

EFFECTS OF RELATIONSHIP TYPE ON QUALITY OF LIFE IN OLDER ADULTS WITH COGNITIVE IMPAIRMENT AND THE INFORMAL CAREGIVERS

Aiping Lai,¹ Julie Richardson,² Lauren Griffith,¹ Ayse Kuspinar,¹ and Jenna Smith-Turchyn,¹ 1. *McMaster University, Hamilton, Ontario, Canada*, 2. *McMaster University, McMaster University, Ontario, Canada*

Purpose: The purpose of this study was to assess whether there was an association between care-recipient relationship type and the QoL of older adults and their informal caregivers, and whether this association pertained to older adults' cognitive function. **Methods:** This was a secondary data analysis. Older adults ($n=1230$) and their informal caregivers ($n=1871$) were identified from participants in the National Health and Aging Trends Study (NHATS) Round 5 and the National Study of Caregiving (NSOC) II. A series of bivariate and multivariable regression models examined the associations among the care-recipient relationship type and QoL in older adults and their informal caregivers, adjusted for socio-demographic variables as well as cognitive functioning. **Results:** Both older adults and caregivers'

QoL outcomes varied by the type of relationship. Recipients cared for by adult-child caregivers or multiple caregivers experienced higher functional limitation than those cared for by spousal caregivers ($\beta=.79$, CI [.39, 1.19]; $\beta=.50$, CI [.17, .82], respectively). "Other" caregivers, such as siblings, friends, etc., had lower odds of experiencing negative emotional burden than spousal caregivers (OR=.26, CI [.13, .52]; OR=.53, CI [.35, .81], respectively). "Other" caregivers were also 51% less likely to experience social strain than spousal caregivers. Lower odds of experiencing negative emotional burdens were also found with multiple caregivers. The association between adult-child caregivers and social strain was explained by the recipients' cognitive function. Conclusions: Care-recipient relationship type impacts the QoL in both recipients and their informal caregivers. This association appears to be affected by care recipients' cognitive function level.

EGG CONSUMPTION AND 4-YEAR CHANGE IN COGNITIVE FUNCTION: THE RANCHO BERNARDO STUDY

Donna Kritz-Silverstein, and Ricki Bettencourt, *University of California San Diego, La Jolla, California, United States*

The role of dietary cholesterol in cognitive decline is unclear. Eggs are a rich source of nutrients and dietary cholesterol. This study examines the association of egg consumption with 4-year change in cognitive function in 890 older, community-dwelling adults. Participants were 357 men and 533 women aged ≥ 55 y (means=70.1 \pm 8.4 and 71.5 \pm 8.8, respectively, $p=0.016$), from the Rancho Bernardo Cohort who attended a 1988-91 clinic visit. Egg intake was obtained with a food frequency questionnaire. Cognitive function was assessed with the Mini-Mental Status Exam (MMSE), Trails B and category fluency, and reassessed in 1992-96. In this sample, rates of egg consumption ranged from never (14.0% of men, 16.5% of women) to ≥ 5 /week (7.0% of men, 3.8% of women; $p=0.0013$). Mean 1988-91 cognitive function scores for men vs. women were 27.5 vs. 27.7 on the MMSE ($p=0.08$), 105.9 vs. 121.6 on Trails B ($p<0.0001$), and 20.2 vs. 18.2 on category fluency ($p<0.0001$). Sex-specific regression analyses examined associations of egg consumption with change in cognitive function. In women, after adjustment for age and education, egg intake was associated with less decline over time in category fluency (beta=-.10, $p=0.01$), which remained significant after adjustment for smoking, alcohol, exercise, cholesterol, calorie intake, and protein intake ($p=0.02$). No other associations were found in women, and no associations were observed in men before and after adjustment for covariates. Results suggest that while high in dietary cholesterol, egg consumption is not associated with decline in cognitive function. For women, there may be a small beneficial effect for verbal memory.

ERECTILE FUNCTION, SEXUAL SATISFACTION, AND COGNITIVE DECLINE IN MEN FROM MIDLIFE TO OLD AGE

Riki Slayday,¹ Tyler Bell,² Michael Lyons,³ William Kremen,² and Carol Franz,² 1. *The Pennsylvania State University, State College, Pennsylvania, United States*, 2. *University of California San Diego, La Jolla, California, United States*, 3. *Boston University, Boston, Massachusetts, United States*

We investigated how changes in erectile function and sexual satisfaction relate to cognitive decline in men from midlife into early old age. This is a major transitional period for increased incidence of erectile function and for cognitive decline. We examined 833 men from the Vietnam Era Twin Study of Aging whose mean ages were 56, 61, and 68 at the time of assessment. Erectile function and sexual satisfaction were measured using scores from the International Index of Erectile Function. Individuals with erectile dysfunction at baseline were excluded. Cognitive performance was measured using factor scores for separate domains of episodic memory, executive function, and processing speed. We tested linear mixed models hierarchically adjusted for demographics, sexual activity, as well as physical and mental health confounders to examine how changes in erectile function and sexual satisfaction related to changes in cognitive function. Declines in erectile function were associated with declines in episodic memory ($p=.004$, $d=.25$), while declines in sexual satisfaction were associated with declines in processing speed ($p=.006$, $d=.19$). Decreasing erectile function and sexual satisfaction may be indicative of individuals also likely to be facing cognitive decline. Possible mechanisms accounting for these changes may include white matter microvascular disease and/or various lifestyle influences. Discussing and tracking sexual health with middle aged men may be a crucial step in identifying those likely to face cognitive decline.

EXAMINING THE IMPACT OF COVID-19 ON LONELINESS AND SOCIAL ISOLATION AMONG AFFORDABLE HOUSING RESIDENTS

Marilyn Mock,¹ Roisin Goebelbecker,¹ Sherry Pomerantz,² Jennifer DeGennaro,² and Elyse Perweiler,² 1. *Fair Share Support Services, Inc./Fair Share Housing Development, Camden, New Jersey, United States*, 2. *Rowan School of Osteopathic Medicine, Stratford, New Jersey, United States*

Loneliness and social isolation are serious public health concerns associated with higher risks of clinical depression, suicidal ideation, coronary artery disease, stroke, functional decline, an increased risk of developing dementia and cancer mortality. Recent reports indicate the prevalence and dangers of loneliness and social isolation have increased as a result of the COVID-19 pandemic, especially among older populations. In order to address these concerns among residents living at Northgate II (NGII), a 302-unit affordable housing development in Camden, NJ, Fair Share Support Services, Inc. (FSSS), the non-profit arm of Fair Share Housing Development, collaborated with the New Jersey Institute for Successful Aging (NJISA) and the DHHS-funded Geriatric Workforce Enhancement Program (GWEP) to develop a loneliness/social isolation survey using two evidenced-based tools, the UCLA Loneliness Scale and the Steptoe Social Isolation Index. FSSS piloted the loneliness and social isolation survey with 192 low-income minority older adults residing at NGII. Results indicate that 49% of the NGII residents surveyed fall into 5 "at-risk" categories: 1) lonely and isolated (9%), 2) lonely/somewhat isolated (8%), 3) lonely/not isolated (9%), 4) isolated/somewhat lonely (9%), and 5) isolated/not lonely (14%). FSSS will utilize survey results and follow-up interviews to tailor social service/other interventions to meet the needs and preferences of residents with

the goal of preventing serious health problems associated with loneliness and social isolation, allowing residents to age in place.

EXAMINING THE IMPACT OF INDIVIDUAL AND SHARED BIOLOGICAL RISKS ON HEALTH AMONG OLDER MARRIED COUPLES

Tai-Te Su,¹ Shannon Meija,² and Richard Gonzalez,³

1. *University of Illinois at Urbana-Champaign, United States*, 2. *University of Illinois, Champaign, Illinois, United States*, 3. *University of Michigan, Ann Arbor, Michigan, United States*

Relationship research has suggested that health among spouses is interdependent and should be considered jointly. Using data from the 2008/2010 and 2016/2018 waves of the Health and Retirement Study (3858 qualified couples; age=67.0±9.6), we investigated the joint influence of married partners' individual and shared cumulative biological risk on future health outcomes. Two risk indicators were constructed to indicate biological health in different domains. Individual grip strength, walk speed, lung function, and cystatin-C were biomarkers selected to construct frailty risk whereas blood pressure, pulse, waist circumference, C-reactive protein, glycohemoglobin, high-density lipoprotein cholesterol, and total cholesterol were biomarkers used to construct cardiometabolic risk. Shared risk was calculated as the number of risks the partners shared. We employed multilevel Poisson regression models to nest partners within couples and examine the effects of individual and shared cumulative risks on future functional limitations. Heckman correction was performed to correct potential selection bias. Our unadjusted models showed individual (frailty: $b=0.22$, $p<.001$; cardiometabolic: $b=0.10$, $p<.001$) and shared (frailty: $b=0.17$, $p<.001$; cardiometabolic: $b=0.08$, $p<.01$) risks are associated with greater future functional limitations. Further, shared cardiometabolic risk moderated the effect of individual risk ($b=-0.01$, $p<.05$). In the adjusted models, the direct associations between shared risks and future functional limitations were explained by indicators of partner selection and shared experiences. In the fully adjusted model, the cross-level interaction for frailty risk became statistically significant. The unique set of dynamics shown in our study offered new insights into understanding how couples influence one another in the context of multisystem biological health.

EXAMINING THE RELATIONSHIP BETWEEN HOSPICE AGENCY CHARACTERISTICS AND COMPLAINT DEFICIENCIES

Xiaochuan Wang, Susanny Beltran, Denise Gammonley, Norma Conner, and Milo Leon, *University of Central Florida, Orlando, Florida, United States*

The U.S. hospice industry has expanded over the last decade. Similar to nursing homes, research guided by the Donabedian framework has documented quality differences in hospice based on agency characteristics, including profit status and rural status. Yet, compared to nursing homes, quality oversight and transparency in hospice remain limited. When families report substandard care, a complaint survey is launched to investigate allegations. Using publicly available regulatory oversight data (e.g., CMS QCOR, Medicare PACUF, CAHPS HIS, Hospice Compare), and guided by the

Donabedian framework, this study describes hospice agency structure and process characteristics associated with care complaint deficiencies (outcome). Of the 4,415 hospice facilities examined, 453 (or 10.3%) have had complaint survey deficiency citations between January 2018 and December 2020. Chi-square and ANOVA tests were conducted to compare facility characteristics (e.g., ownership status, percentage of Medicare beneficiaries in rural zips), nursing and social work involvement, and CAHPS scores between hospices with and without complaint survey deficiencies. Results indicated that the average proportion of beneficiaries with a rural zip for Medicare correspondence was significantly lower in hospices with deficiencies ($p<.001$). Finding also suggested that weekly total nursing and social work minutes were significantly higher in hospices with deficiencies. Additionally, family ratings of hospice team communication, symptom management, and overall satisfaction were higher in facilities without complaint survey deficiencies. Future research and practice implications will be discussed.

EXPERIENCES OF RURAL AND URBAN ASSISTED LIVING COMMUNITIES IN OREGON DURING COVID-19 PANDEMIC

Ozcan Tunalilar,¹ Jason Kyler-Yano,¹ Sheryl Elliott,¹ Sarah Dys,² and Paula Carder,³ 1. *Portland State University, Portland, Oregon, United States*, 2. *Vital Research, LLC, Portland, Oregon, United States*, 3. *OHSU-PSU School of Public Health, Portland, Oregon, United States*

This study presents findings on the impact of the COVID-19 pandemic as reported by a representative sample of Oregon assisted living communities (AL) between December 2020 and March 2021. Of the 559 AL eligible to participate, 346 completed eleven questions related to their experiences since March 2020. These questions covered topics such as access to personal protective equipment (PPE) and accurate information, communication with and support from government agencies, ability to find staff and new residents, ability to address pandemic-related concerns of residents' families and staff, use of virtual visits and telehealth for residents, and visitor restrictions. Response categories ranged from 0 (strongly disagree) to 4 (strongly agree) and we coded "agree" and "strongly agree" responses as having experienced that issue. Among responding AL, 42% were located in rural or frontier areas. We present three findings. First, most AL experienced adverse impact due to COVID-19, especially regarding issues likely to be outside of their control compared to those within their control. Second, while almost all urban-based AL reported that their residents used virtual communication technologies and tools for telemedicine/telehealth (96%) or virtual social visits (96%), rural AL were less likely to report so (90% and 92%, respectively). Finally, rural AL experienced significantly greater staffing difficulties (75%) compared to their urban counterparts (82%). In sum, while all AL would benefit from better regulatory guidance on policies and access to PPE, rural AL might especially benefit from additional, context-specific resources.

FACTORS ASSOCIATED WITH ATTACHMENT AND CARE DECISIONS

Kimberly Cassie, *University of Oklahoma, Tulsa, Oklahoma, United States*

It is widely accepted that remaining in the community for as long as possible is preferable to placement in a care facility. For many, this can only be realized with the support of a family caregiver. Previous research on the relationship between attachment and caregiving decisions is sparse, but tends to suggest there is a relationship between attachment and the decision to assume caregiving responsibilities, but more information is needed to better understand this unique relationship. This exploratory research seeks to address gaps in our understanding by asking is attachment related to the decision to care for a parent and what factors are associated with attachment. A convenience sample of 128 individuals caring for older parents was surveyed to answer these questions. Results indicate lower attachment related avoidance was associated with greater odds of caring for a recipient in the community rather than placing the recipient in a care facility. No relationship between attachment related anxiety and placement decisions was observed. Additionally, greater levels of attachment related avoidance were observed among caregivers reporting lower levels of filial responsibility, more adverse childhood experiences, less perceived support, and greater financial stability. Findings from this study can be used to support the development of interventions to strengthen attachment between adult children and their parents before care decisions are necessary.

FACTORS DRIVING HIGH-NEED HIGH-RISK VULNERABLE VETERANS USE OF OUTPATIENT HEALTHCARE

Ali Vaeli Zadeh,¹ Fei Tang,² Carlos Gomez,¹ Luci Leykum,³ Orna Intrator,⁴ Bruce Kinoshian,⁵ Willy Marcos Valencia,⁶ and Stuti Dang,⁷ 1. *Miami VA Healthcare System, Miami, Florida, United States*, 2. *Miami Veteran Affairs Healthcare System, Miami, Florida, United States*, 3. *South Texas Veterans Health Care System, San Antonio, Texas, United States*, 4. *Canandaigua VA Medical Center, Canandaigua, New York, United States*, 5. *Philadelphia VAMC, Philadelphia, Pennsylvania, United States*, 6. *Medical University of South Carolina, Miami, Florida, United States*, 7. *University of Miami, Miami, Florida, United States*

Using predictive analytic modeling, the Veterans Affairs (VA) Geriatrics and Extended Care Data Analysis Center (GECDAC) identified vulnerable "High-Need High-Risk" (HNHR) Veterans, as requiring more support and services. We sought to identify variables linked with utilization of our outpatient HNHR C4 clinic offering Comprehensive Geriatric Assessment, Care Planning, Care Coordination, and Co-management". Of 724 HNHR Veterans contacted, 531 were reached and invited to participate; 193 were not reached, 326 were reached but declined the C4 clinic, 205 attended the clinic. We compared these groups. Independent variables were organized using Anderson's behavioral model into predisposing (age, gender, race, ethnicity), enabling (drive time, service eligibility, Area Deprivation Index, marital status), and need factors (mental health cognitive condition, ambulatory care sensitive conditions, NOSOS, JFI, CAN, etc.). C4 enrollment acceptance was the outcome. Results showed that compared to patients who declined, HNHR veterans who attended C4 clinic had more chronic health conditions ($p < 0.01$), more service eligibility ($p = 0.01$), more driving time to the closest VA clinic ($p = 0.01$), and more

were married ($p = 0.01$). Patients who declined C4 clinic might have greater barriers to care access. Accessing needed healthcare among HNHR older adults maybe impacted more by enabling factors that allow the individual to seek care if needed and are the resources that may facilitate access to services, rather than need factors, which include individuals' perceptions of their health and functional state, and healthcare needs assessed by professionals. More social and intermediary determinants of health should be incorporated as enabling factors into models striving to understand drivers of healthcare use.

FAMILY CAREGIVER HEALTH IN A PANDEMIC

Kimberly Cassie, *University of Oklahoma, Tulsa, Oklahoma, United States*

Each year family caregivers provide care and services worth billions of dollars to support the needs of older Americans. Their support is invaluable to keep individuals in the community for as long as possible and to allow individuals to attain and maintain their highest practicable level of well-being. But what impact does caregiving have on one's health? Does caregiver health decline with the assumption of caregiving duties? Did caregiver health change during the pandemic? If so, how and what factors are associated with declines in caregiver health? To answer these questions, an exploratory survey was conducted among a convenience sample of 195 family caregiver. Almost a third of those sampled reported excellent or very good health, while 44% reported good health, and almost a quarter reported poor or fair health. Forty-eight percent reported their health had declined since they assumed caregiving duties and 29% reported their health had declined during the pandemic. Employed caregivers and those experiencing less depression/anxiety reported better health. Those experiencing a decline in health with caregiving were more likely to be female, not employed, experienced more stress and more depression/anxiety. Those experiencing a decline in health during the pandemic reported less spirituality, greater attachment related avoidance, and greater depression/anxiety. Findings from this research can be used to inform future research on the effect of the pandemic on family caregiving and to plan interventions to protect caregiver health as they provide vital services to maintain individuals in the community for as long as possible.

FEASIBILITY AND ACCEPTABILITY OF THE TECHNOLOGY-BASED FALL RISK ASSESSMENTS FOR OLDER ADULTS

Ladda Thiamwong,¹ Oscar Garcia,² Renoa Choudhury,² Joon-Hyuk Park,² Jeffrey Stout,² and Rui Xie,² 1. *College of Nursing, University of Central Florida, Orlando, Florida, United States*, 2. *University of Central Florida, Orlando, Florida, United States*

Promising technologies, which are simple, portable, quick, non-invasive, and inexpensive, may open new horizons on fall risk assessments and provide important information for older adults. We used a mixed-methods approach to examine the feasibility and acceptability of technology-based fall risk assessments, including the BTrackS Balance System, Bioelectrical Impedance Analysis, and activity monitoring devices among older adults. Data were collected via a Qualtrics survey and

interviews. The acceptability was measured by the Senior Technology Acceptance (STA) and semi-structured interviews with 15 participants. The STA consists of four domains with 14 items, and the semi-structured interview includes three main questions related to experiences about balance performance tests, body composition, and activity monitoring. One hundred twenty-four community-dwelling older adults completed the online survey, and 15 older adults participated in the interviews. The majority of participants were female, and 72% had no history of falls. Race and ethnicity were 17% Hispanic, 7% African Americans, and 3% Asian Americans. About 7% had COVID-19 positive, 31% reported fear of COVID, and 14.5% were afraid of losing their life to COVID. The word-of-mouth strategy and key person approach were used and had an incredible impact on the recruitment process. None of the participants had ever had their fall risk and fear of falling assessed before agreeing to participate in this study. The technology-based fall risk assessments were feasible and acceptable. About 78% of participants liked the idea of using technology to assess falls risk, and 79% agreed that using technology would enhance their effectiveness in daily activities.

FEASIBILITY AND ACCEPTABILITY OF VIDEOCHAT DURING MEALS IN ADULTS AGING IN PLACE OF AVERAGE AGE 88

Alexa Lyman, and Laura Barre, *Cornell University, Ithaca, New York, United States*

Older adults in the United States prefer to age-in-place. However, living and eating alone are risk factors for malnutrition. Using videochat during mealtimes, i.e., VideoDining, can provide commensality and social facilitation to improve nutritional intake. The objective of this study was to determine if older adults aging-in-place can independently VideoDine with family or friends. We recruited eleven older adults from Full Circle America Steuben, a virtual assisted living program for adults aging-in-place in rural New York. All participants had Amazon EchoShow devices for videochat. Participants were instructed on VideoDining and asked to independently schedule four VideoDine sessions with a family/friend in four weeks. Surveys were collected at baseline, after VideoDine sessions, and end-of-study. Participants were 91% female and 100% white. The average age was 88 years. All participants were widowed and living alone except for one married couple. Overall, 45% of participants VideoDined four times, 36% of participants VideoDined two to three times, and 27% not at all, for an average of 2.7 sessions in a month. Participants VideoDined during all meals, although dinner was most common (66% of meals), and breakfast least common (12% of meals). Average comfort was rated 7.6/10 (1=not comfortable, 10=comfortable), median enjoyment was 9.3/10 (1=not enjoyable, 10=enjoyable), and median ease of VideoDining was 4.1/5 (1=very difficult, 5=very easy). On average, participants rated their VideoDining meal experience a 7.6/10 (1=poor, 10=excellent). With access to videochat technology, older adults can connect with a dining partner and have a favorable experience sharing a meal over videochat.

FEASIBILITY OF IN-HOME SALIVA COLLECTION OF CORTISOL AND DHEA-S AS A BIOMARKER OF STRESS IN DEMENTIA CARE DYADS

Azita Emami,¹ Gabriella Engström,² and Hyejin Kim,³
1. *University of Washington School of Nursing, University*

of Washington, Washington, United States, 2. Dalarna University, Falun, Dalarnas Lan, Sweden, 3. University of Washington School of Nursing, Seattle, Washington, United States

Dementia afflicts affected individuals and their family caregivers worldwide. Although a non-pharmacological intervention has been recommended as a first-line approach to minimize adverse outcomes (e.g., stress) in dementia care dyads (persons with dementia [PWD] and their family caregivers), most evaluations of such interventions have relied on subjective (e.g., self- or proxy-report) rather than objective (e.g., biomarkers) measures. We aimed to explore the feasibility of saliva collection of cortisol and dehydroepiandrosterone sulfate (DHEA-S) as a non-intrusive method in dementia care dyads. Dementia care dyads living at home were recruited from the memory center in Sweden. Prior to the saliva collection, participants received a one-hour education session with a hands-on demonstration led by a trained study coordinator. Participants were instructed to collect saliva three times (two for morning, one for evening)/day, five days/week for eight consecutive weeks. Out of 32 care dyads (32 PWD and 32 family caregivers), 24 (75.0%) completed the saliva collection. On average, 105.5 (87.92%) and 105.9 (88.25%) samples were collected from PWD and family caregivers during eight weeks. There were no statistically significant differences ($p>0.05$) in the average number of saliva samples (i.e., total samples, morning or evening samples) between PWD and family caregivers. The findings of this pilot study showed that saliva collection of cortisol and DHEA-S as a stress measurement was feasible in dementia care dyads living at home. Robust and person-centered procedures, tailored educational materials, and effective communication with dementia care dyads should be considered in future biomarker research on stress in dementia care dyads.

FINANCIAL IMPACTS OF THE COVID-19 PANDEMIC ON U.S. OLDER ADULTS: ASSESSING PANDEMIC-INDUCED JOB AND INCOME LOSS

Walter Dawson,¹ Nora Mattek,² Sarah Gothard,³ and Jeffrey Kaye,³ 1. *Oregon Health & Science University and Global Brain Health Institute, Portland, Oregon, United States, 2. Oregon Health and Science University, Portland, Oregon, United States, 3. Oregon Health & Science University, Portland, Oregon, United States*

The COVID-19 pandemic has greatly impacted the economic security of millions of older adults. Job loss and reductions in personal income were significant in 2020 stemming from pandemic-induced shutdowns that temporarily closed large swaths of the U.S. economy. Yet, the specific financial impacts of the pandemic on older adults, including family care partners, are not well understood. To understand the COVID-19 pandemic's effects on the health and financial well-being of older adults, we gathered data from the Research via Internet of Technology and Experience (RITE) Study, a longitudinal survey panel providing data from thousands of participants of various ages and backgrounds in the U.S. on their use of healthcare and technology (N=1,365). We measured by population strata including age, sex, and education and other characteristics including caregiver status. Adults between 20-40 years of age experienced the highest rate of job loss and reduction in wages (33%) as a result of the pandemic, while adults aged >70 years experienced

the lowest rate (12.5%). However, adults aged 50-60 and 60-70 also experienced relatively high levels of job loss at (28.4% and 25.7%, respectively). Behavior changes and disruptions to typical routines to avoid COVID-19 infections may have contributed to job and personal income loss amongst Individuals aged 50-60 and 60-70. However, these findings suggest potentially high levels of economic insecurity amongst individuals who continue to work into late-life. These results may help policymakers understand how to better tailor interventions and policies to mitigate economic insecurity, particularly for populations disproportionately impacted by the pandemic.

FOCUS GROUP FINDINGS OF TRIAL PARTICIPANTS IN A CAREGIVER PSYCHOSOCIAL INTERVENTION: SAVVY CAREGIVER PROGRAM

Maria Aranda, Iris Aguilar, and Rene Maldonado,
University of Southern California, Los Angeles, California, United States

Previous work highlights the importance of sociobehavioral interventions to address dementia caregiving health and wellbeing outcomes. By empowering caregivers to become objective managers of their loved one's illness, and own self-care, they are less likely to exhibit negative outcomes. We are conducting a mixed-method, randomized trial to test manualized, multi-family psychoeducational group interventions: Savvy Caregiver Express, and Savvy Caregiver Program. This poster describes the qualitative findings of four focus group interviews recently conducted to elucidate the study participation experiences of family caregivers enrolled in the parent study. Twenty-five racially and ethnically diverse participants (21 women, 4 men) caring for a family member with cognitive decline participated in focus group interviews conducted via videoconferencing methods. We captured more nuanced experiences from the perspective of study participants with regards to the caregiver interventions and their research participation. Interviews were conducted by trained research personnel, lasted 60-75 minutes, and followed an open-ended questioning route. Based on thematic analyses, we identified the following themes: 1) Changing one's mindset: Seeing life through their shoes; 2) Getting information in one place; 3) Expanding the personal experience; 4) Fears and vulnerability; 5) Time constraints vs. wanting more; 6) Not everyone is at the same place; 7) Technology: It's going to be part of our lives; and 8) Research: Not always in sync. Our findings indicate high satisfaction with most components of the program while specific recommendations were offered to improve the intervention and study experience such as tailoring materials to stage-specific needs.

GENOMIC SEQUENCING OF SOD1Δ YEAST THAT ESCAPE SPORE DEATH

Temiloluwa Adanlawo,¹ and Helen Vander Wende,² *1. Howard University, Washington, District of Columbia, United States, 2. University of California Berkeley, Berkeley, California, United States*

Amyotrophic lateral sclerosis (ALS) is a devastating neurodegenerative disease that impacts nerve cells and the spinal cord, which in some cases are linked to mutations in

the Superoxide Dismutase 1 (SOD1) gene. Sod1 is an anti-oxidant within cells that converts reactive oxygen from superoxide into water using a copper and zinc ion to deactivate the oxygen. When the SOD1 gene is deleted, yeast cells are still able to undergo meiotic divisions and generate four spores, but the spores that are produced are inviable. However, we see that randomly, *sod1Δ* spores can grow on rich media. This leads us to hypothesize that somewhere in the genome, there is a suppressor mutation that allows these cells to grow. We tested this hypothesis by preparing samples for whole genome sequencing. By comparing the genomic sequences from our suppressor mutants to wild-type controls, we're able to identify a single point mutation within a gene called NCA2, which codes for a protein that regulates expression of Fo-F1 ATP synthase subunits 6 and 8. Given this result, we are now working to try and understand the relationship between the *sod1Δ* spore death phenotype and the modulation of ATP synthase activity. In summary, the results from our work have the potential to further help us understand what role Sod1 plays in yeast meiosis and may be able to give us a deeper understanding for ALS cases that are linked to Sod1.

GOALS OF CARE CONVERSATIONS IN NURSING HOME AND ASSISTED LIVING CARE PLAN MEETINGS

Gail Towsley,¹ Djin Tay,² and Linda Edelman,¹ *1. University of Utah College of Nursing, Salt Lake City, Utah, United States, 2. University of Utah, Salt Lake City, Utah, United States*

Me & My Wishes is a novel systematic approach for long-term care residents living with dementia to record videos about their care preferences that can be shared with staff and families in care plan meetings. To understand how the videos were utilized in Goals of Care (GOC) conversations, we coded and analyzed transcripts of recorded care plan meetings at the time of sharing the video using a priori codes derived from GOC conversation elements. Coding discrepancies were resolved in team meetings; finalized codes were summarized to derive themes. Thirty-four care plan meeting conversations between residents (n=34), family members (n=29) and staff (n=35) were analyzed. Residents appreciated sharing personal histories and preferences via video, while staff members appreciated deeper understanding of residents' care preferences. Two themes described care plan meeting conversations: Everyday Care - a checklist-style assessment of the resident's daily care (e.g., help with activities of daily living), activities engaged in and satisfaction with care; and Clarifying Care Goals - checking the resident's treatment preference (e.g., pain management, CPR), explaining hospice, or confirming the resident's contact person. Several elements of GOC were not discussed (e.g., disease progression) and conversations lacked depth and comfort evidenced by apologetic language and abrupt transitions of topics rather than exploring alignment of goals with care preferences. Me & My Wishes videos are a mechanism for residents to voice preferences. Standardized guidance, which is lacking in long-term care, is needed to help care teams engage in meaningful conversations to ensure alignment of goals and treatment preferences.

HEALTH EQUITY IMPLICATIONS OF COVID-19 ON DEMENTIA CARE IN COMMUNITY FOR PEOPLE OF AFRICAN DESCENT

Mary Lukindo,¹ Barbara Hamilton-Hinch,¹ OmiSoore Dryden,¹ and Katie Aubrecht,² 1. *Dalhousie University, Dalhousie University, Nova Scotia, Canada*, 2. *St. Francis Xavier University, St. Francis Xavier University, Nova Scotia, Canada*

This presentation shares results from an analysis of interviews conducted to understand the health equity implications of COVID-19 responses on dementia care in the community for people of African descent in Nova Scotia, Canada. Interviews were embedded within a larger multi-method rapid research project that aimed to assess the impact of COVID-19 on dementia care for geographically and socially marginalized groups in the province. Data from the interviews was analyzed using a constructivist thematic analysis method, guided by an intersectional theoretical scaffold. Three themes were identified related to systemic barriers, mental health, system navigation and self-care, and collected under the overarching theme of ‘facing the unknown with dementia’. Results emphasized the value and notable absence of community driven, culturally specific dementia programs, resources and navigators for people living with dementia, family caregivers and care workers of African descent. Participants identified lack of health system and care provider knowledge and understanding of the cultures and histories of people of African descent as a barrier to quality care and to addressing dementia-related stigma. Conversations focused on the need for practical and accessible tools, strategies and perspectives responsive to the actually lived realities and needs of people in community, and for research that actually contributes to individual and collective life in tangible, timely and culturally meaningful ways. Recommendations focus on the importance of centering community in dementia care programs, policy, practice and research to improve services and supports for people of African descent.

HOPE AS A MOTIVATOR FOR HEALTHY BEHAVIORS IN OLDER ADULTS: FINDINGS FROM A CROSS-SECTIONAL SURVEY

Mushira Khan,¹ Patrick Hill,² Catherine O'Brien,³ and Dugan O'Connor,³ 1. *Mather Institute, Plainfield, Illinois, United States*, 2. *Washington University in St. Louis, St. Louis, Missouri, United States*, 3. *Mather, Evanston, Illinois, United States*

Hope can be understood as a motivational state that enables people to move toward their goals. Yet, how hope may act as a motivator for healthy behaviors in older adults is not well-understood. Further, the extant literature utilizes varied conceptualizations of hope, and a better understanding of the constructs that underlie the relationship between hope and health behaviors is needed. This study examined the relationship between hope and health behaviors, explored how this relationship may differ across different socio-demographic groups, and considered how hope relates to perceived future selves among older adults. Community-dwelling adults 55 years and older (n = 711; mean age 67.38 years; 280 men, 431 women) completed an online, cross-sectional survey. Survey measures included, along with the Adult Hope Scale (AHS) and the Herth Hope Index (HHI), a health behaviors

checklist, self-reported health, and a future self scale. We found a moderately strong positive correlation between hope and healthy behaviors in older adults (AHS $r = 0.46$, $p < .01$; HHI $r = 0.50$, $p < .01$). Participants with higher levels of hope also reported more positive future selves and better health. The associations were similar across different racial/ethnic groups and the magnitude of this effect held even after controlling for gender, education, marital status, and income. Of the two hope scales, we recommend the AHS measure given its relative parsimony, greater use in the field, and the fact that the associations were fairly similar to the HHI with respect to health and health behavior.

HOSPITAL, EMERGENCY DEPARTMENT, AND HOME HEALTH USE IN OLDER ADULTS WITH SENSORY IMPAIRMENT

Laura Wallace,¹ Karen Hirschman,¹ Mary Naylor,¹ Liming Huang,² and Pamela Cacchione,³ 1. *University of Pennsylvania, Philadelphia, Pennsylvania, United States*, 2. *University of Pennsylvania, University of Pennsylvania, Pennsylvania, United States*, 3. *University of Pennsylvania, University of Pennsylvania School of Nursing, Pennsylvania, United States*

Hearing, vision, and dual (combined hearing and vision) sensory impairments (HI, VI, and DSI) are common in older adults and associated with adverse health outcomes. However, it is not clear how sensory impairments impact healthcare utilization in older adults. This study aims to examine hospital, emergency department (ED), and home health care use amongst adults 65 and older diagnosed with HI, VI, and DSI in an urban academic health system. This secondary analysis (N=45,000) used a limited data subset of older adult primary care patients' EHR data from a parent study examining medical complexity, healthcare use, and social vulnerability. Using logistic regression and controlling for participant demographics and comorbidities, results show HI, VI, and DSI increase the likelihood of having an ED visit (OR 1.29, $p < .0001$; OR 1.28, $p = 0.0011$; OR 1.50, $p = .0328$, respectively) and a home health episode (hearing OR 1.41, $p < .0001$; vision OR 1.42, $p = .0002$) compared to those without sensory impairment (SI). No significant difference was found in hospital use and home health use for DSI. This is the first known study to examine ED use for older adults with VI and DSI, and home health use for older adults with SI in the US. Findings suggest older adults with SI have greater utilization and dependence on healthcare services. Older adults with SI may benefit from outpatient assessments and interventions to mitigate risks of ED use. Findings also support research into the drivers of healthcare use amongst this population, financial implications, and intervention development to prevent avoidable healthcare use.

HOSPITAL-INDUCED DELIRIUM AMONG MEDICAL OLDER ADULTS: EVALUATING THE VERACITY OF PROGNOSTIC MODELS

Urszula Snigurska,¹ Ragnhildur Bjarnadottir,¹ and Robert Lucero,² 1. *University of Florida College of Nursing, Gainesville, Florida, United States*, 2. *University of California Los Angeles, Los Angeles, California, United States*

Several prognostic models have been developed and validated for delirium prediction among older adults. However,

model development and validation studies need to be evaluated for risk of bias to establish the veracity of the prognostic models. This is a critical step before they can be implemented in clinical practice. Multiple systematic reviews have evaluated prognostic models of hospital-induced delirium. However, none of the existing systematic reviews evaluated the validity of models for non-surgical, medical hospitalized older adults. We conducted a scoping review to evaluate the validity of existing prognostic models of hospital-induced delirium in medical older adults. CINAHL, PsycINFO, PubMed, and Web of Science were searched for original studies. The database search yielded 4,312 records. Five studies were included in the qualitative synthesis. All the studies claimed to have developed valid prognostic models. However, the risk of bias assessment revealed that existing prognostic models of hospital-induced delirium in medical older adults are at a high risk of bias. Collectively, the statistical analysis was the greatest source of bias. Notably, while we have seen a proliferation of prognostic models for use in the surgical older adult population, efforts at developing prognostic models in the medical older adult population seem to have declined since the early 1990s. Newer methods of data collection, such as data mining of electronic health records, and statistical analysis, such as machine learning, have shown promise in accurate prediction of hospital-induced delirium while overcoming many challenges associated with manual data collection and traditional statistical analyses.

HOW CAN WE ENCOURAGE OLDER ADULTS TO ADOPT DIGITAL SERVICES?

Yutong Xie,¹ Jiayi Wu,² and W. Quin Yow,³ 1. *River Valley High School, Singapore, Singapore*, 2. *River Valley High School, Singapore, Singapore*, 3. *Singapore University of Technology & Design, Singapore, Singapore*

Majority of older adults (OA) do not use technology frequently. For example, 84% of Singapore OA own a smartphone, however, only 22% have tried apps like online shopping. Similarly, 42% of US OA own a smartphone, yet one-third of them have never used the internet. Past research indicated poorly designed user interfaces as a barrier to technology use. Based on the Technology Acceptance Model (TAM), we hypothesize that OA-friendly user interfaces can increase perceived usefulness (PU) and perceived ease of use (PEOU) of technology, which would translate into increased digital services adoption rate. Forty healthy participants aged 65 to 86 (6 males, 34 females, mean age = 72.3) were recruited through OA activity centers in Singapore and assigned to either control or experimental groups. Both groups used an online website to perform specific shopping tasks and answered a TAM questionnaire. The control group used a website modeled after current websites while the experimental group used an OA-friendly website designed based on literature review and pre-survey, with features like OA-friendly mode, tutorial and online helpdesk. Data analysis was conducted using an independent sample t-test and bootstrapping. The experimental group showed a significantly higher proficiency in performing tasks ($p=0.037$), PEOU ($p=0.049$), and PU ($p=0.044$) than the control group. This suggests that user interfaces friendlier to OA increases their acceptance of technology, which could translate into a higher digital service adoption rate. Therefore, this research

sets the basis for further research on digital services guidelines for older adults, including for telehealth and others.

IMPACT OF RESTRICTED CONTACT BETWEEN GRANDPARENTS AND GRANDCHILDREN DURING THE COVID-19 PANDEMIC

Verena Klusmann,¹ Sara Cengiz,² Carina Materna,² and Christian Spreckels,² 1. *University of Konstanz, Berlin, Berlin, Germany*, 2. *University of Hamburg, University of Hamburg, Hamburg, Germany*

To combat the COVID-19 pandemic strict contact restrictions have been imposed on institutions for both older and younger people, social structures have been locked down, families have been urged to reduce contact with older relatives, and people over 65 have been temporarily banned from their workplaces and from attending events, both in public and private spaces. These measures are assumed to have a number of psychosocial consequences. For this questionnaire study, 268 pupils (7-to-10 years-old) of nine different schools in Hamburg, Germany, with different social index were asked about how they experienced, perceived, and behaved during the COVID-19 pandemic. 75% of the children reported on restricted contact to their grandparents: While 41% did not meet their grandparents at least for a certain time at the beginning of the pandemic, 34% did not meet their grandparents during the whole first year of the pandemic. Of those who met their grandparents, 25% kept physical distance to them. These contact restrictions were significantly higher in schools with a lower social index, $\chi^2(8)=15.49$, $p=.05$. Those children who never met their grandparents also reported on higher perceived stress, $t(220)=-2.37$, $p=.019$, $d=-.33$, tended to have lower subjective well-being, $t(223)=-1.73$, $p=.09$, $d=-.24$, and had higher risk perceptions concerning COVID-19 infections, $t(223)=-2.18$, $p=.03$, $d=-.31$. Hence social isolation and loneliness is not only an issue for older people themselves, but contact restrictions also potentially increase the stress load and impair the well-being of children who have to do without support and care of their grandparents in sensitive developmental phases.

INFLAMMATORY BIOMARKERS AND SEX HORMONES INTERACT TO PREDICT ECOLOGICALLY-ASSESSED COGNITIVE PERFORMANCE

Erik Knight,¹ Erin Harrington,² Martin Sliwinski,³ Jennifer Graham-Engeland,⁴ Jelena Pavlovic,⁵ and Christopher Engeland,⁴ 1. *University of Colorado Boulder, Boulder, Colorado, United States*, 2. *Pennsylvania State University, University Park, Pennsylvania, United States*, 3. *The Pennsylvania State University, University Park, Pennsylvania, United States*, 4. *Penn State University, University Park, Pennsylvania, United States*, 5. *Albert Einstein College of Medicine, Bronx, New York, United States*

Inflammatory biomarkers and sex hormones have been investigated as independent risk and resilience factors for cognitive decline in older adults. Many sex hormones are anti-inflammatory and there is emerging evidence that sex hormones may buffer the risk for cognitive decline associated with higher inflammation. However, few studies have included concurrent examination of inflammation and sex hormones in studies of cognitive performance and cognitive

aging. A diverse sample of older adults (N = 245; 65% female, 42% Black, 13% Hispanic; mean age = 76.8 years) had blood drawn before and after a two-week measurement burst that included three cognitive tests (6x per day) assessing working spatial memory, perceptual speed, and feature binding. Testosterone, estradiol, estrone, and six basal cytokine concentrations were quantified. Composite scores of basal inflammation were calculated. Multilevel modeling indicated that heightened inflammation related to poorer spatial working memory performance (B = 0.213, 95%CI[0.11, 0.414], p = .040). In addition, sex hormones moderated the association of cytokine concentration with perceptual speed (e.g., basal cytokines x testosterone: B = 0.13, [-0.24, -0.03], p = 0.013; similar effects evident for estrogens). Decomposition these interactions revealed that heightened inflammation predicted poorer performance, but only among individuals with lower sex-hormone concentrations. This study provides evidence of immune and hormonal-by-immune associations with performance in two cognitive domains in older adults. Examining the functional crosstalk between immune and sex hormone functioning will improve understanding of risk and resilience factors related to cognitive performance and help predict cognitive decline in older adults.

IN-HOME ONLINE MUSIC THERAPY FOR PSYCHOLOGICAL HEALTH AMONG CAREGIVERS OF PERSONS WITH DEMENTIA: A PILOT STUDY

Hyejin Kim,¹ Gabriella Engström,² Töres Theorell,³ and Azita Emami,⁴ 1. *University of Washington School of Nursing, Seattle, Washington, United States*, 2. *Dalarna University, Falun, Dalarnas Lan, Sweden*, 3. *Karolinska Institutet, Stockholm, Stockholms Lan, Sweden*, 4. *University of Washington School of Nursing, University of Washington, Washington, United States*

Family caregivers who provide care to persons with dementia (PWD) in a home setting may feel greater stress, depressive symptoms, or struggle to deal with issues in their lives. Indeed, PWD often require 24-hour care that includes ensuring safety, providing emotional support, and assistance with activities of daily living and multiple instrumental activities of daily living. This study examined the short-term effects of an online music intervention on stress, coping, and depression among caregivers of PWD. We included 35 caregivers (n=24 [intervention group], n=11 [comparison group]) living at home with their family member with dementia. Mann-Whitney U test and Wilcoxon signed-ranked test were performed to examine between- and within-group differences from baseline to eight weeks after the intervention. The coping subscale yielded a significant difference between the groups at post-test (U=76.50, Z= -1.978, p=0.048), indicating the intervention group had better coping than the comparison group at post-test. Significant within-group differences in overall stress (Z= -2.200, p= 0.028) and coping subscale (Z= -1.997, p=0.046) in the comparison group at post-test suggest that overall stress and coping were maintained from baseline to post-test in the intervention group, whereas the comparison group had significantly higher overall stress and lower coping at post-test. This home-based online music program showed potential benefits for caregivers of PWD by taking into account participants' musical

preferences and ease of access to the program. A randomized controlled trial with a larger sample size and objective measurements of stress and depressive symptoms (e.g., biomarkers) should be conducted in the future.

INTAKE OF FLAVONOIDS AND ODDS OF FRAILTY ONSET IN ADULTS IN THE FRAMINGHAM OFFSPRING COHORT

Thuy Nga Nguyen,¹ Courtney Millar,² Douglas Kiel,³ Marian Hannan,² and Shivani Sahni,² 1. *University of Arizona, Tucson, Arizona, United States*, 2. *Hebrew SeniorLife, Roslindale, Massachusetts, United States*, 3. *Hebrew SeniorLife, Hebrew SeniorLife, Massachusetts, United States*

Polyphenols (antioxidants derived from plant-foods) could play a role in inhibition of oxidative stress and frailty reduction, yet data on the polyphenol subclass of dietary flavonoids is limited. This study sought to determine the association between dietary flavonoids and frailty onset in middle-aged and older adults. This prospective cohort study included non-frail individuals from the Framingham Offspring Cohort (FOC) with total flavonoid intake (mg/day; defined as sum flavonols, flavan-3-ols, flavonones, flavones, and anthocyanins via Harvard Food Frequency Questionnaire), frailty (via Fried phenotype), and covariate information measured at baseline (1998-2001). Follow-up frailty was evaluated in 2011-2014. Logistic regression estimated odds ratio (OR) and 95% confidence intervals (95% CI) adjusting for relevant confounders. Participants (n=1,701; 55.5% female) had a mean age of 58.4 years (SD ± 8.3). Mean flavonoid intake was 309 mg/d (SD ± 266). After 12.4 years (SD ± 0.8), 224 (13.2%) individuals exhibited frailty. In age and sex adjusted models, every 50 mg/day of higher total flavonoid intake was associated with 3% reduced odds of frailty [OR (95%CI): 0.97 (0.94-1.00), p-value: 0.05]. Further adjustment for smoking, energy and protein intake, and disease indicators did not appreciably change the association, and associations became non-significant (p-value=0.12). Thus, there was no association between flavonoid intake and odds of frailty onset in adults in the FOC. This could be due to participants' higher intake of flavonoids compared to average intake of ~200 mg/d in Americans.

INTERGENERATIONAL CONNECTIONS TO IMPROVE SOCIAL WELL-BEING OF OLDER ADULTS WITH ADRD: A RESEARCH PROTOCOL

Ling Xu,¹ Noelle Fields,¹ Kathryn Daniel,¹ Brooke Troutman,² and Daisha Cipher,³ 1. *University of Texas at Arlington, Arlington, Texas, United States*, 2. *USAF Academy, USAF Academy, Colorado, United States*, 3. *UTA, Arlington, Texas, United States*

There is growing concern about social isolation, loneliness, and diminished emotional well-being among persons with ADRD who live in the community. Research suggests that reminiscence strategies, especially with the production of a digital story book, combined with an intergenerational approach may yield significant benefits for older adults. Reminiscence approaches are typically implemented by trained professionals. However, the use of trained volunteers is of growing interest due to the costs associated with

reminiscence programs. This research protocol describes the development and testing of an intergenerational, telephone-based reminiscence program offered by trained, young adult volunteers that includes the use of digital storytelling (DST). Specifically, the study addresses three aims: 1) Quantitatively test the effectiveness in improving social and emotional well-being of older adults with ADRD; 2) Quantitatively test attitudes towards aging and knowledge and awareness of ADRD disease among the young adults; and (3) Qualitatively evaluate the usefulness of this intervention from perspectives of the dyads. A randomized control trial is used to assess the effects of the intervention using an explanatory sequential mixed methods design. The older and younger participants (n = 92 dyads) are randomly assigned to intervention (reminiscence) or sham (social visit) group, and then randomly matched. Data are collected at baseline, mid-intervention, post-intervention, 3 months-post intervention and through qualitative interviews (selected dyads). The proposed evaluation activities will allow us to determine the applicability of intergenerational reminiscence with DST as an effective intervention for supporting the social and emotional needs of persons with ADRD.

IS “CULTURE” NEEDED IN ABORIGINAL ELDER CARE STATION? AN STUDY FROM THE PERSPECTIVE OF SERVICE PROVIDERS

Li-Chuan Liu, *National Taitung University, Taitung, Taitung, Taiwan (Republic of China)*

Many studies show that cultural perspective is an important factor in caring for elderly tribal adults. To understand the level of attention that the Cultural Health Station of Indigenous People attaches to culture during its operation, this study selected Taitung County as the region of study. A qualitative focus group research method and quantitative questionnaire, we try to understand “What are the demands of elderly tribal adults?” “Do services provided by the Tribal Cultural Health Station satisfy the demands of elderly tribal adults?” and “What are the gaps between the service demands and provided to elderly tribal adults?” The results showed that service providers believe that culture is markedly important to elderly tribal adults, that culture-based care designs offered by the Tribal Cultural Health Station is currently insufficient, and that to enhance the capacity of the multiethnic Tribal Cultural Health Station, the cognition and understanding of policy makers and enforcers must be elevated.

LARGE SCALE SURVEY RESEARCH WITH OLDER ADULTS/PERSONS WITH DISABILITIES IN A PUBLIC HEALTH CRISIS

Sarah Dys,¹ Hannah Huebner,² Norma Carrillo-Van Tongeren,¹ Courtney Sirk,¹ Harold Urman,¹ and Cathy Coddington,¹ *1. Vital Research, LLC, Los Angeles, California, United States, 2. Vital Research, LLC, Vital Research, California, United States*

Best practice for measuring quality improvement and consumer satisfaction of health and human services for older adults and people with disabilities relies on in-person survey administration. This poster highlights adaptation strategies undertaken across three large-scale evaluation studies of program/service delivery conducted during the COVID-19

pandemic, necessitating a departure from in-person techniques: 1) Integrated Satisfaction Measurement for the Program of All-Inclusive Care for the Elderly (I-SAT-PACE), 2) National Core Indicators- Aging and Disabilities/Intellectual and Developmental Disabilities (NCI-AD/IDD), and 3) Assisted Living Resident Quality of Life (AL-QOL). Data collection for these projects occurred from September 2020 to August 2021, providing an opportunity to showcase project adaptation over the course of the pandemic. Using project implementation examples across 15 states and approximately 10,100 participants, we discuss implications for successful survey coordination, interviewer training, data collection, and participant/stakeholder engagement during a public health emergency. Strategies included pivoting to phone, Zoom, and paper-based data collection and increasing technical assistance for field staff and participants. Project teams were able to increase access to participation by implementing multimodal survey delivery, mitigate coronavirus exposure, continue collecting older adults and people with disabilities’ experiences, and compare results based on method of delivery. Technology barriers, field staff dropout, need for larger sample sizes, and inclusion of participants with dementia, hearing, and speech impairments present important tradeoffs to consider. These examples indicate it is possible to administer hybrid data collection methods across populations with varying cognitive and physical abilities without compromising data quality.

LIKE A DEW DROP ON A LOTUS LEAF: PERCEPTIONS OF AGING WELL IN SOUTH ASIAN AMERICAN OLDER ADULTS

Mushira Khan,¹ Sheetal Shah,² and Ajla Basic,³ *1. Mather Institute, Plainfield, Illinois, United States, 2. University of California (Davis), Sacramento, California, United States, 3. Mather, Evanston, Illinois, United States*

Past research has underscored four key themes prevalent in popular and scientific discourse on successful aging in North America – the emphasis on individual agency and control; continuing productive activity into old age; the value of independence in late life; and an ideal construction of permanent personhood, wherein the realities of mortality and decline are inadequately addressed (Lamb, 2014). Yet, the meanings attached to successful aging differ across cultures and are not very well-understood. The Perceptions of Aging Well in Diverse Populations study aims to acquire a holistic understanding of the attitudes and beliefs around aging well across cultures and to identify the similarities and differences in these perceptions within diverse racial and ethnic groups. This presentation highlights preliminary findings from in-depth, semi-structured qualitative interviews with South Asian Americans 50 years and older (n=19; 9 men, 10 women). Participants shared that a sense of inevitability and aging with “grace”, “dignity”, and “wisdom” were key components of successful aging. Maintaining good health, keeping a positive attitude, and remaining independent in later life appeared motivated primarily by a desire to remain connected to, but not necessarily “burden” adult children with caregiving responsibilities. Religious faith and spiritual well-being, availability of support systems, and a sense of community were key facilitators. Limited English proficiency and loneliness posed challenges to aging well, particularly in

late-life immigrants. These findings provide unique insights into subjective perceptions of successful aging and may help inform programs and policies that support the health and well-being of older South Asian Americans.

LONG-TERM CARE AND WIDE EFFECTS ON CHILDREN CAREGIVERS -- NEW EVIDENCE FROM TAIWANESE ADMINISTRATIVE DATA

Kuan-Ming Chen,¹ Chen-Wei Hsiang,² Yu-Hsuan Chou,³ Shiau-Fang Chao,⁴ Kuan-Ju Tseng,² Ming-Jen Lin,³ Ya-Mei Chen,³ and Shih-Cyuan Wu,³ 1. *National Bureau of Economic Research, CAMBRIDGE, Massachusetts, United States*, 2. *National Taiwan University, National Taiwan University, Taipei, Taiwan (Republic of China)*, 3. *National Taiwan University, Taipei, Taipei, Taiwan (Republic of China)*, 4. *National Taiwan University, Taipei City, Taiwan (Republic of China)*

Long-term care (LTC) needs have profound impacts on the care-receivers and their children. Past research has focused on primary caregivers' short-term responses to LTC needs on limited aspects. This study brings new Taiwanese administrative data on health insurance, LTC program usages, and tax records. Rich information allows this study to explore long-term impacts on care-receivers' extended families. Event study combined with various regression analyses is the main framework of this study. Using the longitudinal record of more than 23 million individuals older than 65 over 18 years, the present study examines extended family members' various outcomes along the LTC needs trajectory. Among others, these outcomes include labor market participation and health expenditures. There are several findings in this study. Parents' LTC needs decrease all children's average full-time labor force participation by 2.5 percentage points even 10 years after the needs incurred. These needs do not directly increase children's health expenditure. A precise zero effect is found on children's health expenditure before, during, and after parents' LTC needs. Nevertheless, parents' health status or LTC risks, in general, may still pass on to children through other channels. The inter-generational health association is found to be approximately 0.25, indicating some degree of transmission. The results suggest that the impacts of LTC needs on family members are profound and widespread. Policy needs to address multiple aspects to cater to potential difficulties for care-receivers' family members.

MEASUREMENT INVARIANCE OF A LATENT DEMENTIA INDEX BY GENDER IN THE AGING, DEMOGRAPHICS, AND MEMORY STUDY

Joseph Saenz,¹ Alice Kim,² and Christopher Beam,² 1. *UNIVERSITY OF SOUTHERN CALIFORNIA, Los Angeles, California, United States*, 2. *University of Southern California, University of Southern California, California, United States*

Population-based aging studies allow researchers to study dementia and its correlates. Few include dementia diagnoses. Latent variable models have been used to create latent dementia indexes (LDI) using cognitive and functional ability to approximate dementia. The LDI is applied across diverse populations, but it is unclear whether gender affects its measurement properties. We assess whether the LDI can be

used to measure dementia equivalently for men and women. We use the 2001-2003 Aging, Demographics, and Memory Study (n=856, 355 men, 501 women). Cognitive ability was assessed using memory, executive function, attention, spatial ability, orientation, and language tasks. Functional ability was informant-reported. We used confirmatory factor analysis to test factorial invariance across gender and compare latent means to determine which group had lower means, consistent with greater dementia likelihood. Model fitting results suggest metric invariance of the LDI but only partial scalar invariance across gender. Latent mean differences in the LDI were observed ($M_{diff} = .39$, $SE = 0.19$, $p = .042$), with women lower, on average, than men. Correlations between LDI and dementia diagnosis were stronger for both men ($r = -.82$) and women ($r = -.85$) than correlations between dementia and Mini-Mental Status Exam scores ($-.69$ and $-.73$, respectively). The LDI may be reliably and validly used to measure and compare dementia likelihood in men and women. Results suggest lower LDI scores in women, indicating greater dementia likelihood. Gender differences may be partially attributed to differences in measurement properties of items, possibly due to gender differences in educational returns and employment factors.

MEASURING COVID-RELATED AGEISM

Amanda Sokan,¹ Mindy Fain,² Jake Harwood,³ Kathleen Insel,⁴ Zhao Chen,⁵ and Linda Phillips,⁶ 1. *The University of Arizona, University of Arizona, Arizona, United States*, 2. *University of Arizona Center on Aging, Tucson, Arizona, United States*, 3. *University of Arizona, University of Arizona, Arizona, United States*, 4. *University of Arizona, Tucson, Arizona, United States*, 5. *The University of Arizona, Tucson, Arizona, United States*, 6. *College of Nursing, University of Arizona, Arizona, United States*

Prejudice, discrimination, and negative stereotypes based on age (ageism) are long-standing and strongly implicated in poor health outcomes and limited access to health care for older adults. Recent writings suggest the COVID-19 pandemic raised the specter of ageism to an entirely new level. Do these observations reflect an exaggeration of "usual" ageism or a unique manifestation of intergenerational tension rooted in resentments of younger people concerning COVID-related disruptions in their lives believed to be primarily a function of older people's vulnerability to the disease phenomenon? To address this question, the purpose of this study was to develop and test an instrument to measure ageist tendencies associated with the COVID-19 pandemic. Scale items, written to reflect attitudes about paternalism, inconvenience, and sacrifice, were assessed for content validity. Then the 12-item scale was administered to 227 undergraduate and graduate students in the health and social sciences. Analysis showed items have strong internal consistency and concurrent and discriminant validity. Importantly the scale explained unique variance over and above other standard measures of ageism. Ageism is deeply embedded in global and U.S. culture and strongly related to negative outcomes. This scale will assist researchers investigating the ageist consequences of the current pandemic and help us to monitor what could be long-term residual ageist effects of the COVID pandemic.

MONTANI SEMPER LIBERI: AGE AND DEPRESSION AMONG VETERANS IN APPALACHIA

Alex Dang,¹ Maxwell Nimako,² and Amy Fiske,³

1. *West Virginia University, West Virginia University, West Virginia, United States*, 2. *WVU, West Virginia University, West Virginia, United States*, 3. *West Virginia University, Morgantown, West Virginia, United States*

Depression is higher in rural areas and military veterans (Kimron et al., 2019; Bedard-Gilligan et al., 2018). West Virginia, the only state contained entirely within Appalachia, has a higher percentage of military service among its citizenry than other states. Thus, the purpose of the current study was to examine the association between veteran status and depression among adults in WV. Using 2018 WV data from the CDC's Behavioral Risk Factor Surveillance System, we examined depression as a function of veteran status and age, among 612 younger adults, 1813 middle-aged adults, and 2445 older adults (N = 4,870; 12.4% veterans). Our ANOVA revealed a significant overall effect, $F(5, 4864) = 14.64, p < .001$, a main effect for veteran status (18.8% of veterans and 26% of non-veterans reported depression), and an age effect emerged, with more younger (28.6%) and middle-aged adults (30.5%) reporting depression than did older adults (20.3%). No significant interaction between age and veteran status emerged, $F(2, 4864) = 1.75, p = .175$. Of note, 25% of the sample reported having depression. Given that place-based mental health disparities exist, this finding is not unexpected. But fewer older adults and fewer veterans reported depression. At least three possibilities warrant further investigation. Future studies should examine whether these age and veteran status differences in depression reflect differences in resilience, differences in reporting, and/or differences in selective survival.

OLDER ADULTS PERFORMED WORSE ON COGNITIVE ASSESSMENT AT LONELIER MOMENTS: USING AMBULATORY ASSESSMENT APPROACH

Jee eun Kang, Karra Harrington, and Martin Sliwinski,
The Pennsylvania State University, University Park, Pennsylvania, United States

This study focused on investigating the short-term effect of loneliness on older adults' cognitive performances in daily life. Loneliness is suggested as a risk factor for cognitive health, but results in previous studies are inconsistent due to the lack of valid measures and limited research design. The attention-depletion hypothesis highlights that acute stress could immediately compromise cognitive ability by consuming attentional resources. Accordingly, this study examined whether loneliness, as one of the stressors related to one's social relationship, was immediately associated with worse daily cognitive performances in older adults. Using an ecological momentary assessment approach, 311 community-dwelling older adults (Mage=77.5 (range=70-90), 67% female, 45% white) reported their level of loneliness as well as performed cognitive assessment five times a day for 16 days. Multilevel modeling showed that on occasion when participants reported a higher level of loneliness than normal, they performed worse in the processing speed test ($p < .01$) and the short-term memory binding test ($p < .01$) during those moments, controlling for age, gender, education, ethnicity, IADL, and retest-practice effect. Moreover, those

momentary associations between loneliness and cognitive performances remained significant after controlling for the momentary level of feeling depressed. Unlike the concurrent effect, there was no lagged effect of loneliness on daily cognitive performances. These results suggest that transient but intense feelings of loneliness can function as acute stress and thus, compromise daily cognitive functioning short-term. Results will be discussed in terms of the potential benefit of momentary real-time interventions to lessen feelings of loneliness to maintain older adults' cognitive functioning.

OLDER ADULTS' ACCEPTANCE OF TECHNOLOGY DURING THE PANDEMIC: THE COVID TECHNOLOGY ACCEPTANCE MODEL (TAM)

Megan O'Connell,¹ Kristen Haase,² Allison Cammer,¹ Shelley Peacock,¹ Theodore Cosco,³ and

Lorraine Holtslander,¹ 1. *University of Saskatchewan, Saskatoon, Saskatchewan, Canada*, 2. *University of British Columbia, Vancouver, British Columbia, Canada*, 3. *Simon Fraser University, Vancouver, British Columbia, Canada*

During the pandemic, technology-mediated communication was one of the few ways to maintain social and community connections. We explored how the pandemic impacted older adults' use and appraisal of technology. In a random sample of 407 older adults (M age = 81.1 years; range 65-105 years) almost half (n = 161) reported they changed how they used technology to virtually connect with others during the pandemic, and 78 of these reported that this was new technology for them. We adapted the technology acceptance model (TAM) for the pandemic, the COVID-TAM, and describe how physical distancing led to new acceptance of technology due to an increased perception of usefulness of technology for maintaining community and social connections. The 71 older adults who denied using technology were asked about the reasons underlying their reluctance to use technology to access social networks and community events during the pandemic. Thematic analysis revealed factors consistent with a double-digital divide; lack of physical exposure to technology creates an additional psychological barrier to adoption of new technology. Of the technology-reluctant subgroup of older adults, few reported lack of perceived usefulness of technology during the pandemic. Instead, most reported lack of self-efficacy or fear of technology underlying their lack of technology use for social and community connections during the pandemic, which we incorporate into the COVID-TAM. Findings indicate that technology training can help mitigate this fear and increase social and community connections that are technology-mediated in circumstances where physical distancing is necessary.

OUTCOMES AND TREATMENT COSTS OF SKILLED NURSING FACILITY PATIENTS WITH PRESSURE INJURIES AND MALNUTRITION

Kirk Kerr,¹ Cory Brunton,¹ and Mary Beth Arensberg,²

1. *Abbott Nutrition, Columbus, Ohio, United States*, 2. *Abbott, Columbus, Ohio, United States*

Skilled nursing facilities (SNF) provide care for individuals requiring skilled care while transitioning to a more permanent residence post hospitalization. This analysis shows that diagnosed malnutrition and pressure injuries (PI) adversely impact SNF patients' health and recovery.

Length of SNF stay, total charges, and discharge disposition were analyzed using SNF claims from 2016–2020 Centers for Medicare & Medicaid Services (CMS) Standard Analytical File databases. An average of 4.5% SNF patients had diagnosed PIs, and 4.9% had diagnosed malnutrition. Patients with diagnosed malnutrition were more likely to have PIs than patients without diagnosed malnutrition (11.9% vs 4.1%). Patients with PIs had higher charges (\$12,304 vs. \$10,937), were less likely to be discharged home (11.1% vs 18.9%), and more likely to be discharged to a hospital (15.8% vs 11.0%) or deceased (2.8% vs 1.6%). Patients with diagnosed malnutrition displayed a similar pattern for charges (\$11,587 vs \$10,969), and discharge to home (14.5% vs 18.8%), hospital (13.5 vs 11.1%) or deceased (2.8% vs 1.6%). Length of SNF stay did not differ between patients with and without PIs (18.5 vs 18.6) and was slightly shorter for patients with diagnosed malnutrition (17.3 vs 18.9). While higher probability of rehospitalization or death could impact these results, drivers behind these differences need further investigation. Because malnourished patients were more likely to have PIs and both PI and malnutrition are associated with poorer patient discharge outcomes and higher costs, efforts to identify malnutrition and implement proper nutrition interventions should be prioritized as part of SNF quality improvement initiatives.

PAVING THE WAY FOR AGEIST ATTITUDES THROUGH CHILDREN'S BOOKS

Lena-Emilia Schenker, and Jennifer Bellington, *Friedrich Schiller University Jena, Jena, Thuringen, Germany*

Older adults are underrepresented and rarely appear in major roles in children's literature. According to developmental intergroup theory, numerically smaller groups are likely to become targets of stereotypes and prejudice. Because parental ageist attitudes are related to those of their children, and parents typically choose their children's literature, we investigated parental preferences for books featuring older and younger adults and what factors might predict this preference. In an online survey, 176 parents of children aged 12 or younger rated children's book covers featuring a child and a prominent younger or older adult. There were two identical versions of each book cover on which only the age of the adult varied. Each respondent viewed covers featuring older and younger adults, but only saw one version of each cover (i.e., counterbalanced design). Parents indicated their preference for the books by stating how much they and their children would like the book and how likely they would be to buy it. Stereotypical expectations regarding the books' storylines were rated on a semantic differential scale (e.g., modern vs. old-fashioned). Results revealed that there were no significant differences in preferences for books featuring younger, compared to older adults. However, a stronger difference in preference for books featuring younger, over older adults was predicted by the extent of stereotypical expectations regarding the storylines. In particular, this preference was stronger in parents who expected stories with older adults to conform to prevailing ageist stereotypes, suggesting that ageist expectations may deter some parents from books featuring older adults.

PHYSICAL INDICATORS OF AGING ARE RELATED TO CELLULAR SENEESCENCE SIGNAL P16INK4A IN MIDLIFE ADULTS

Kelly Rentscher, Teresa Seeman, Steve Cole, and Judith Carroll, *University of California, Los Angeles, Los Angeles, California, United States*

Cellular senescence signal p16INK4a has been identified as a biomarker of aging that accumulates with chronological age across several tissues in mice and humans and may be potentially modifiable by interventions. This study examined whether physical indicators of aging were associated with p16INK4a and other markers of the aging process in midlife adults. Participants were 543 adults aged 26–78 years (Mean=54.0; 50.5% female) in the Midlife in the United States Refresher cohort. Interviews, questionnaires, and performance tests measured physical indicators of aging, including the Fried frailty index, limitations in daily activities, and age-related comorbidities. RNA sequencing of whole blood assessed biomarkers of aging: p16INK4a (CDKN2A), the DNA damage response (DDR), and the senescence-associated secretory phenotype (SASP). Older age was associated with enhanced p16INK4a ($r=.11$, $p=.01$), DDR ($r=.34$, $p<.001$), and SASP ($r=.38$, $p<.001$) expression. Multiple regression models that adjusted for age, sex, race/ethnicity, BMI, comorbidities, and time between assessments revealed that frailty (pre-frail/frail vs. non-frail) was associated with greater p16INK4a ($B=0.13$, $p=.048$) and marginally greater DDR ($B=0.06$, $p=.06$) expression. Limitations in daily activities were also associated with p16INK4a ($B=0.12$, $p=.045$). History of heart disease, stroke, arthritis, and cancer were associated with DDR and SASP expression in unadjusted models only ($ps<.05$). In summary, senescence indicator p16INK4a was elevated in whole blood samples from middle-aged adults who showed signs of frailty and limitations in daily activities. Findings suggest that whole blood p16INK4a expression might potentially be used to detect early signs of aging and target interventions to reduce biological aging and frailty.

POOR PERFORMANCE IN SNF-VBP PROGRAM IS ASSOCIATED WITH WORSE COVID-19 OUTCOMES IN NURSING HOMES

Jennifer Gaudet Hefele,¹ Matt Aldag,² Riad Elmor,² Charanya Kaushik,² and Jessica Simpson Ballard,² *1. Booz Allen Hamilton, Hollis, New Hampshire, United States, 2. Booz Allen Hamilton, Bethesda, Maryland, United States*

Skilled Nursing Facility Value-Based Purchasing (SNF-VBP) was a new Medicare payment program when COVID-19 began. SNF-VBP aims to improve care through payment bonuses and penalties. However, studies have shown that minority-serving nursing homes (NHs) tend to fare worse under SNF-VBP (more likely to receive penalties, less likely to receive bonuses). This study sought to examine whether SNF-VBP performance prior to the pandemic was associated with COVID-19 outcomes and whether associations varied in NHs where the majority of residents are Black/African American (majority-Black/AA). Using publicly available data on COVID-19 outcomes and vaccinations, SNF-VBP performance, and NH characteristics, we found that majority-Black/AA NHs were less likely to have zero infections; had higher case fatality rates; and had lower resident and staff

vaccinations rates compared to NHs where the majority of residents are White. Across all NHs, worse SNF-VBP performance was associated with worse COVID-19 outcomes (the bottom quintile of SNF-VBP performers were more likely to experience COVID-19 infections and had lower vaccination rates; the highest performers had higher vaccination rates). However, in stratified analyses, SNF-VBP performance was not significantly associated with COVID-19 outcomes in majority-Black/AA NHs compared with majority-White NHs. The association between poor SNF-VBP performance and poor COVID-19 outcomes is concerning. Overall findings suggest that SNF-VBP performance prior to the pandemic is an important indicator of subsequent COVID-19 outcomes. However, it is unclear whether poor SNF-VBP performance is signaling overall poor quality or whether it is signaling a financial disadvantage caused by the program itself that in turn impacted COVID-19 outcomes.

PRECARIOUS AGING: A WORKING DEFINITION

Amanda Grenier,¹ Christopher Phillipson,² Grace Martin,³ Abiraa Karalasingam,³ Karen Kobayashi,⁴ Patrik Marier,⁵ and Debbie Laliberte-Rudman,⁶ 1. *University of Toronto and Baycrest Hospital, Toronto, Ontario, Canada*, 2. *The University of Manchester, Manchester, England, United Kingdom*, 3. *University of Toronto, Toronto, Ontario, Canada*, 4. *University of Victoria, Victoria, British Columbia, Canada*, 5. *Concordia University, Montreal, Quebec, Canada*, 6. *Western University, London, Ontario, Canada*

Until recently, studies of precarity have overlooked aging and late life. This poster presents a snapshot of conceptual work in progress on a Canadian Social Sciences and Humanities Research Council (SSHRC) Insight Grant on precarity and aging. The poster outlines existing definitions and theoretical perspectives, key results, a current evolving conceptual model, and a working definition of Precarious Aging. It situates existing knowledge and definitions of precarity, highlights crucial intersectional locations of gender, im/migration and (dis)ability, and clarifies the concept of precarity in later life. Results at this point in the study are based on conceptual reviews, reviews of literature on precarity and aging, and the consideration of allied concepts. In conclusion, the concept of precarity offers a promising lens to guide research in the field of social and critical gerontology, providing a foundation for an enhanced understanding of the lives and realities of older people with regards to aging, disadvantage, and inequality.

PREDICTING CAREGIVER REACTIONS TO CHALLENGING BEHAVIORS IN THE CONTEXT OF DEMENTIA

Darby Simon, and Benjamin Mast, *University of Louisville, Louisville, Kentucky, United States*

Challenging behaviors exhibited by people living with dementia have been associated with a variety of negative outcomes including greater caregiver burden, nursing home placement, and lower quality of life. Although there has been considerable research on psychological and behavioral changes in dementia, little research has explored family caregiver reactions to these changes and what caregiver characteristics are associated with stronger emotional reactions. This research examined the relationship between

established indicators of caregiver mental health (depression, burden, grief, well-being) and caregiver reaction scores on the Revised Memory and Behavior Problems Checklist (RMBPC). The sample consisted of 76 family caregivers for people living with dementia, aged 25 to 93, who participated in a study on caregiver burden and grief. Multiple regression was used to predict RMBPC caregiver reaction scores from the Zarit Burden Inventory, Geriatric Depression Scale, Ryff Psychological Well-Being Scale, and Anticipatory Grief Scale while controlling for RMBPC total behavior frequency scores. RMBPC total behavior frequency scores and Zarit Burden Inventory were significant predictors of caregiver reaction scores ($F(2,74) = 87.559$, $p < .001$, $R^2 = .703$). More frequent, challenging behaviors were associated with more distressing reactions and higher caregiver burden also predicted more distress on the RMBPC reaction scores. Psychological well-being was associated with lower reactions at the bivariate level but was not significant in the full regression model. Future research is needed to better understand these relationships and implement this knowledge to benefit family caregivers.

PREDICTORS OF NURSING HOME COVID-19 CASES: A COMMUNITY VULNERABILITY APPROACH

Matthew Peterson,¹ and Larry Lawhorne,² 1. *UNC Wilmington, Wilmington, North Carolina, United States*, 2. *Wright State University, Fairborn, Ohio, United States*

It is well known that the Covid-19 pandemic has placed considerable burden on nursing homes, including from resident, facility, and community perspectives, among others. This study examined facility and community factors that were related to incident Covid-19 cases in nursing home facilities. $N=12,473$ US nursing homes were included in this study. Data from June 2020 - January 2021 from several publicly available sources were combined to create a dataset that included facility name, size, ownership, mortality rate, Covid case rate, personal protective equipment (PPE) and staff shortages, % white residents, and % Medicaid residents. Community factors included core-based statistical area (CBSA) Covid case rates, urban/rural, CBSA death rates, and the CDC's Social Vulnerability Index (SVI). Zero-inflated Poisson regression models were used to determine predictors of 8-month Covid case counts, normalized by facility size. Results indicated that higher staff shortages, poorer facility rating, for-profit ownership, proportionally more Medicaid and non-white residents were all significantly associated with higher Covid case rates over 8 months (all $P < 0.0001$). Significant community level predictors of higher cases included urban setting and higher SVI. PPE shortages was not associated with higher case counts. Of all the factors included, SVI was the strongest predictor of Covid case counts. This large US study assists in determining critical facility and community factors that predict increasing Covid burden in nursing homes. Particularly, SVI is an important factor in determining facility and public health policy, and targeting resources in large scale health crises such as the Covid-19 pandemic.

PROJECT ECHO-AGE FRIENDLY COMMUNITY CARE: APPLYING THE ECHO® MODEL WITH AREA AGENCY ON AGING STAFF

Katherine Bennett,¹ Mary Pat O'Leary,² and Elizabeth Phelan,¹ 1. *University of Washington, Seattle, Washington, United States*, 2. *Aging and Disability Services*

- Seattle/King County, Aging and Disability Services -
Seattle/King County, Washington, United States

The Extension for Community Healthcare Outcomes (ECHO®) model originated at the University of New Mexico to improve access to specialty care in underserved communities via telehealth and has spread worldwide. It has been utilized to improve geriatrics care with interprofessional participants but not specifically to train community case managers in Age-Friendly care and community initiatives. This is a program evaluation of an ECHO developed exclusively for Area Agency on Aging (AAA) case managers via a community-campus partnership. Twenty-eight AAA staff (including 15 case managers) participated in a 6-session series (March through April 2021) focused on the 4Ms of Age-Friendly care (What Matters, Medication, Mentation, and Mobility). Each one-hour session included a mini-didactic and at least one case presented by participants utilizing a novel age-friendly case form. Participants completed pre and post surveys to assess self-efficacy in applying Age-Friendly principles on 5-point scales. Surveys were anonymous and analyzed comparing pre-post using Mann-Whitney U tests. Of the 28 participants, 86% completed pre and 65% post-surveys. Self-efficacy for providing Age-Friendly care improved from 2.58 pre to 4.5 post ($p < 0.001$) and for providing recommendations to colleagues on Age-Friendly care from 3.4 pre- to 4.5 post ($p < 0.001$). Participants showed significantly increased self-efficacy ($p < 0.05$) pre vs. post on 14/15 Age-Friendly care items. One hundred percent would recommend this ECHO program to a colleague. This pilot utilizing Project ECHO with AAA staff increased their self-efficacy for providing Age-Friendly care and suggests this may be an effective tool to bridge the Age-Friendly Health Systems and Age-Friendly Community initiatives.

SOCIAL SUPPORT AND SOCIAL STRAIN AS PREDICTORS OF DEPRESSIVE SYMPTOM TRAJECTORIES FOLLOWING A MARITAL TRANSITION

Emily Denning,¹ AnneMarie O'Neill,¹ Sheila Markwardt,² Anda Botosaneanu,³ Heather Allore,⁴ Corey Nagel,⁵ David Dorr,² and Ana Quiñones,² 1. *Portland State University, Portland, Oregon, United States*, 2. *Oregon Health & Science University, Portland, Oregon, United States*, 3. *University of Michigan - Dearborn, Dearborn, Michigan, United States*, 4. *Yale School of Medicine, New Haven, Connecticut, United States*, 5. *University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*

We investigated trajectories of depressive symptoms over 10 years following a marital transition (widowed or divorced) using data from the Health and Retirement Study ($N = 377$, mean age = 67.55 years; years 2006-2016). Piecewise growth curve models were estimated to investigate whether social support and strain from one's spouse, measured prior to transition, predicted depressive symptom trajectories following the transition. Covariates included sex, age, education, race/ethnicity, wealth, and chronic conditions. Overall, trajectories of depressive symptoms after a marital transition were significantly negative, indicating a decrease in depressive symptoms over time. Findings did not differ significantly between participants who were widowed and those

who were divorced. Spousal social support was associated with an increase in depressive symptoms and spousal social strain was associated with a decrease in depressive symptoms following a marital transition in separate models: support: $b = .250$, $SE = .062$, $p < .001$; strain: $b = -.209$, $SE = .095$, $p < .05$. However, social strain was not significant when examined jointly with social support. Depressive symptoms declined significantly for low ($b = -.370$, $SE = .100$, $p < .001$) and average levels of social support ($b = -.113$, $SE = .037$, $p < .01$), but not for high levels of spouse social support ($b = .143$, $SE = .109$, $p = .188$). These results suggest those with the highest levels of spousal support prior to the transition, whether divorced or widowed, experienced a more difficult recovery and may be targets for additional mental health support following a marital transition.

SPOUSES' EMOTION REGULATION SKILLS AND DEPRESSIVE SYMPTOMS IN THE CONTEXT OF EARLY STAGE DEMENTIA

Amanda Piechota,¹ and Joan Monin,² 1. *Yale School of Public Health, New Haven, Connecticut, United States*, 2. *Yale School of Public Health, New Haven, Connecticut, United States*

In older adults, the suffering of a relative with chronic disease or illness can severely impact their caregiver. However, older adults also tend to have better emotional regulation than younger age groups. Very little is known about these dynamics in the context of early-stage dementia in which both spouses are struggling with caregiving or experiencing dementia and need one another for support. In the present study, we hypothesized that when both partners have better emotion regulation skills, each partner's depressive symptoms would be the lowest. We made the same hypothesis for both the person with dementia and their spouse without dementia. We used self-report baseline data from an intervention study of 70 older adult married couples ($N=140$) where one spouse has early-stage dementia. Spouses completed questionnaires that measured their emotional regulation habits (Difficulties in Emotion Regulation Scale) and their recent depressive symptoms (CESD). Results from the actor partner interdependence model showed that when both partners had high emotional regulation skills scores there were the lowest levels of depressive symptoms for each dyad member ($B=4.31$, $SE=.94$, $t(49.9)=4.61$, $p < .001$). Findings suggest couple-focused interventions to enhance emotion regulation skills are important for coping in the early stages of dementia.

STATE VARIATION IN POTENTIALLY BURDENSOME TRANSITIONS AMONG ASSISTED LIVING RESIDENTS AT END OF LIFE

Xiao (Joyce) Wang,¹ Joan Teno,² Pedro Gozalo,¹ David Dosa,¹ Kali Thomas,³ and Emmanuelle Belanger,⁴ 1. *Brown University, Providence, Rhode Island, United States*, 2. *Oregon Health & Science University, Portland, Oregon, United States*, 3. *Brown University, Brown University/Providence, Rhode Island, United States*, 4. *Brown University School of Public Health, Providence, Rhode Island, United States*

Little is known about the quality of end-of-life care in assisted living (AL), particularly transitions at end of life. This

study aims to provide a first national look at potentially burdensome transitions at end of life among AL residents and to examine how those vary by state. This is a retrospective cohort study of Medicare beneficiaries who died in 2018 and resided at a validated 9-digit ZIP code for an AL with 25 or more beds⁴ on the 120th day before death (N=37,668). Three types of potentially burdensome transitions were considered: 1) healthcare transitions during last 3 days of life, 2) three or more all-cause hospitalizations during the last 90 days of life, and 3) two or more hospitalizations for urinary tract infections, sepsis, pneumonia, and dehydration during last 120 days of life. Hospitalizations and decedents' locations were obtained from multiple administrative claims records. Out of the 37,668 AL decedents, 7,015 (18.6%, 95% CI: 18.2%-19.0%) experienced at least one potentially burdensome transition. States varied widely in the rate of burdensome transitions, ranging from 30.9% in North Dakota to 8.9% in Wyoming. Our results support quality concerns for end-of-life care among AL residents. Future studies are needed to explain state variation and how it relates to factors such as residents' co-morbidities, end-of-life care practices in AL, and state regulations. This study had two limitations. First, multiple hospitalizations for Medicare Advantage beneficiaries might be under-reported. Second, the results are not generalizable to persons in ALs with fewer than 25 beds.

STEREOTYPES OF OLDER ADULTS, OLDER MEN, AND MALE LEADERS PREDICT EXPECTATIONS, STANCE, AND VOTING INTENTIONS

Caitlin Monahan,¹ Ashley Lytle,² Elizabeth Inman,³ Marybeth Apriceno,⁴ Jamie Macdonald,⁵ and Sheri Levy,⁴
 1. *Stony Brook University, Brooklyn, New York, United States*, 2. *Stevens Institute of Technology, Hoboken, New Jersey, United States*, 3. *Stony Brook University, Stony Brook University, New York, United States*, 4. *Stony Brook University, Stony Brook, New York, United States*, 5. *St. Francis College, Brooklyn, New York, United States*

The 2020 U.S. Presidential Election offered a unique opportunity to examine how stereotypes of older adults, older men, and male leaders impact expectations of candidate job performance and intentions to vote for Biden or Trump. This online study involved 500 college students from two universities from September 30th until November 3 (Election Day). A Biden and Trump model were tested for the relationships among (a) stereotypes from public discourse with (b) expectations of candidates/ presidential performance with (c) voting stance (pro- and anti-Biden vs pro- and anti-Trump) and (d) intentions to vote for Biden/Trump. As expected, for the Biden model, endorsement of older adult (lesser endorsement of senile, unhealthy), male leadership (greater endorsement of assertive and collaborative, lesser endorsement of uncaring), and older male stereotypes (greater endorsement of elder statesman and family-focused) predicted greater expectations of Biden's performance, which predicted pro-Biden and anti-Trump stances and ultimately voting intentions for Biden. As expected, for the Trump model, endorsement of older adult (lesser endorsement of senile), male leadership (greater endorsement of assertive, collaborative, lesser endorsement of immoral and uncaring), and older male stereotypes (greater endorsement of elder statesman) predicted greater expectations of Trump's performance, which

predicted pro-Trump and anti-Biden stances and ultimately voting intentions for Trump. Taken together, these results suggest examining relevant categories of stereotypes associated with candidates and voting stances provides a fuller picture of voting behavior toward multiple candidates vying for office in addition to political ideology and voting intentions.

SYSTEMATIC REVIEW OF PSYCHOLOGICAL AGING RESEARCH IN NEPAL

Kezang Tshering,¹ Srijana Shrestha,² and Barbara Kamholz,³
 1. *Wheaton College, Wheaton College, Massachusetts, United States*, 2. *Wheaton College, Norton, Massachusetts, United States*, 3. *UCSF, UCSF, California, United States*

Nepal faces unprecedented levels of aging similar to trends in many less well-resourced countries. It has limited capacity to address the medical, social and psychological needs of older persons. Difficult choices regarding allocation of resources will be needed. In this review, we hope to clarify what is already known in aging research in Nepal. The databases APA PsychINFO and PubMed were searched. The inclusion criteria were peer-reviewed articles on i) psychological constructs and mental illnesses, ii) use of original data, iii) inclusion of senior participants and iv) studies conducted in Nepal. Studies that included mixed age group and cross-country comparisons were excluded from this review. The initial search resulted in 76 articles from APA PsychINFO and 590 articles from PubMed. Articles were reviewed independently for inclusion and exclusion criteria. A total of 49 articles were included in the final list. Preliminary results showed that the largest share of articles focused on depression (32.1%), followed by quality of life/life satisfaction or loneliness (18.9%). A large number of studies also examined prevalence rates of psychiatric and neurocognitive disorders (22.6%). Common conditions, like dementia and delirium were studied only in 1.9% and 3.8% of published studies respectively. All of the studies were cohort-based and none focused on evaluations of psychosocial/medical interventions. Robust intervention studies are needed to help improve the lives of seniors in Nepal. To our knowledge this is the first comprehensive review of published articles on psychological construct in aging populations in Nepal.

TELE-HEALTHCARE IN RESEARCH AND EDUCATION: AGE DIFFERENCES IN ACCESS AND UTILIZATION OF HEALTHCARE RESOURCES

William Hills,¹ Matthew Murphy,¹ and Karen Hills,² 1. *Coastal Carolina University, Conway, South Carolina, United States*, 2. *Beaufort Jasper Hampton Comprehensive Health Services, Conway, South Carolina, United States*

Societal needs highlighted during the pandemic have led to significant changes in healthcare, including the rapid development and implementation of tele-care consumer options. This study examined video-based, virtual healthcare access and utilization before and during the pandemic. Participants included traditional college-aged students, middle-aged adults, and retirement-aged persons (n = 685); measures included access to physical and mental health services, consumer satisfaction with type of services accessed, and anticipated use of virtual healthcare following the pandemic. Results showed that approximately half of participants (49.2%) had experience with virtual

healthcare, with most of these cases during the pandemic. Virtual healthcare was more often used for physical compared to mental healthcare services, with college-aged participants more likely to use mental healthcare services than adult and retirement-aged participants. Laptop computers were most widely used to access services, with smartphone use proportionally lower in retirement-aged participants (31.4%). Overall satisfaction with virtual services was high (Mdn = 5 on a 6-point Likert scale), but college-aged participants trended toward a lower satisfaction (Mdn = 4.25) than other age categories. These results support that virtual healthcare service development and access experienced significant growth during the pandemic. Age differences in the types of services, types of devices, and satisfaction with virtual services all suggest a similar theme for age-related considerations of life stage, life responsibilities, and comfort and familiarity with technology that must be addressed for virtual healthcare to reach its full potential and reach equitably across the lifespan.

THE EFFECT OF A VIRTUAL REALITY DELIVERED PHYSICAL ACTIVITY INTERVENTION ON THE PHYSICAL FUNCTION OF OLDER ADULTS

Kyle Kershner,¹ Jason Fanning,² Joy Furlipa,² Peter Brubaker,² Amber Brooks,³ Lindsey Page,¹ and Diane Ehlers,¹ 1. *University of Nebraska Medical Center, Omaha, Nebraska, United States*, 2. *Wake Forest University, Winston-Salem, North Carolina, United States*, 3. *Department of Anesthesiology, Wake Forest School of Medicine, North Carolina, United States*

COVID-19 public health recommendations have prohibited many older adults from attending in-person physical activity (PA) programs that improve physical function and promote functional independence. Most PA programs have shifted towards a video conference (VC) format, but this modality has been noted to “flatten” the social experience which is fundamental for lasting behavior change. Virtual reality (VR) is now designed for immersion and place-presence and may be better suited for instilling a feeling of social connection, which will likely improve physical function. The purpose of this study was to evaluate differences in physical function after a 4-week in-home VR or VC based PA intervention. Low-active adults (66.8±4.8 years) were randomized to VR (n=5) or VC (n=4) based PA counselling and instructed to find activities that were intrinsically motivating. VR participants were asked to select pre-approved available active games in addition to enjoyable real-world activities. ANCOVA models were used to explore group differences in six-minute walk distances across time. Results are reported using η^2 effect sizes based on the small sample size. After controlling for baseline values, the ANCOVA models revealed a moderate-to-large magnitude effect for distance traveled during the six-minute walk test ($\eta^2=.10$). Additionally, the VR group participants walked 42.63 meters further, which approaches a clinically meaningful difference. These promising early findings suggest there is value to exploring the impact of VR-delivered, group-mediated activity promotion on physical functioning in older adults. Future research should investigate aspects of VR that promote increased social connection and physical function in the older adult population.

THE HERITABILITY OF COGNITIVE AGING: A SYSTEMATIC REVIEW OF LONGITUDINAL TWIN STUDIES

Alice Kim,¹ Alyssa Kam,¹ Maxwell Kofman,² and Christopher Beam,¹ 1. *University of Southern California, University of Southern California, California, United States*, 2. *University of Southern California, Los Angeles, California, United States*

Heritability of cognitive ability changes across late adulthood, although whether genetic variance increases or decreases in importance is not understood well. We performed a systematic review of the heritability of cognitive ability derived from longitudinal twin studies of middle-aged and older adult twins. Using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, articles were identified in APA PsycINFO and Clarivate Web of Science electronic databases. Identified articles were screened by title and abstract; remaining full-text articles were then fully evaluated. Reference sections served as an additional method for identification of relevant articles. In total, 3,106 articles were identified and screened, 28 of which were included and were based on data from 10 longitudinal twin studies published from 1994-2021. There are large genetic influences on an initial level of cognitive performance across domains whereas there are small to moderate genetic influences on change in performance with age. Evidence was less definitive about whether the same or different genetic factors contribute to both level and change. Non-shared environmental influences appeared to drive individual changes in cognitive performance. Heritability tended to either be stable or decline after 65 years, possibly because of the increasing importance of non-shared environmental influences on cognitive ability. Recent studies report increases in heritability across specific subtests and domains. Shared environmental variance accounted for little variance in cognitive ability. Emerging research questions and future directions for understanding genetic and environment influences in the context of gene-environment interplay are highlighted in this review.

THE IMPACT OF AGE ON MOBILE TECHNOLOGY USE DURING THE COVID-19 PANDEMIC

Yi Lin, and Graham Rowles, *University of Kentucky, Lexington, Kentucky, United States*

The COVID-19 pandemic led to quarantines and mandatory spatial distancing; people of all ages were encouraged to use technologies instead of actual human contact as part of COVID-19 prevention. The promotion of mobile applications (apps) during the pandemic influenced mobile technology use behavior. This study explored age differences in mobile technology use during the COVID-19 pandemic. A pilot-tested survey was distributed using online survey software. Persons surveyed were 35 years of age or older, currently living in the United States of America with experience using mobile technology. Survey questions pertained to mobile technology use frequency and factors influencing the decision to use mobile technology. The nationwide response included 1212 individuals. The average age of participants is 56.12±12.26 years old (female: male = 1.24:1). Responses were categorized participants into three age groups, 35 to 49, 50 to 64, and 65 or older. Daily mobile technology use frequency increased significantly ($p<0.01$) for all groups

during the COVID-19 pandemic, with participants 35 to 49 having a significantly higher ($p < 0.01$) use frequency than other groups. Regarding factors influencing the decision to use mobile technology, 64.1% of respondents aged 50 to 64 identified the necessity of using this technology during the pandemic as a significant factor, and 64.0% of participants in age 65 or older reported that the availability of functions on mobile devices is critical. Overall, the COVID-19 pandemic led to a significant increase in mobile technology use with people in different age groups differentially valuing the factors that affected their user behavior.

THE IMPACT OF HCBS USE PATTERNS ON OLDER ADULTS' PHYSICAL FUNCTION AMONG CONTINUOUS SERVICE USERS

Ya-Mei Chen,¹ Shih-Cyuan Wu,¹ Kuan-Ming Chen,² Chen-Wei Hsiang,³ Shiau-Fang Chao,⁴ Ming-Jen Lin,¹ Ji-Lung Hsieh,⁵ and Yu-Hsuan Chou,¹ 1. *National Taiwan University, Taipei, Taipei, Taiwan (Republic of China)*, 2. *National Bureau of Economic Research, CAMBRIDGE, Massachusetts, United States*, 3. *National Taiwan University, National Taiwan University, Taipei, Taiwan (Republic of China)*, 4. *National Taiwan University, Taipei City, Taiwan (Republic of China)*, 5. *Graduate Institute of Journalism, Taipei City, Taipei, Taiwan (Republic of China)*

Background Taiwan, one of the fastest aging countries in the world, provides home-and community-based services (HCBS) care recipients through the second 10-Year Long-Term Care Plans (LTC Plans 2.0). The current study aimed to examine the impact of continuous use of HCBS offered by LTC plan 2.0 on older adults' physical function change overtime. Methods This study used the LTC Plan 2.0 database and the National Health Insurance Plan claim dataset, and included 157,682 clients who had applied for and were evaluated for LTC services for the first time from 2018 through 2020 and continuously used any LTC Plan 2.0 services for six months. Outcome variables were measured by activities of daily living (ADLs) and instrumental activities of daily living (IADLs) between baseline assessment and the assessment after the six months of service utilization. Latent class analysis and generalized estimating equations were used to investigate the influences of different service use patterns on the changes in physical functions. Results Three subgroups of LTC recipients with different use patterns, including home-based personal care (home-based PC) services ($n = 111,976$; 71.01%), professional care services ($n = 31,584$; 20.03%), and community care services ($n = 14,122$; 8.96%) were identified. When compared to care recipients in the community care group, those in the home-based PC group improved more in IADL scores, and the professional care group improved more ADL scores. Conclusion Those receiving more professional services made more progress in ADL ability, but those in home-based PC made more progress in IADL ability.

THE IMPACT OF SUPERVISOR SUPPORT ON THE JOB SATISFACTION OF IMMIGRANT AND MINORITY LONG-TERM CARE WORKERS

Frances Hawes,¹ and Shuangshuang Wang,² 1. *University of Wisconsin-Eau Claire, Eau Claire, Wisconsin, United States*, 2. *Shandong University, School of Public Health, Cheeloo*

College of Medicine, Jinan, Shandong, Shandong, China (People's Republic)

The need for long-term care workers (LTCW) will grow significantly as the American population ages. Understanding the factors that impact job satisfaction of this workforce has important implications for policy and practice. Previous research has demonstrated the effect of supervisor support on the job satisfaction of these workers; however, much less is known about how this effect differs among different race/ethnicity or immigration groups. This study examined how supervisor support mediates the associations between race/ethnicity, immigration status, and job satisfaction among nursing assistants (NAs). Data of 2,763 NAs were extracted from the National Nursing Assistant Survey (2004). Race/ethnicity groups included White (54%), African American (30%), Asian (2%), Hispanic (10%), and others (4%). Immigration status included U.S.-born citizens (87%), naturalized (7%) and resident/alien (6%). Bivariate analyses showed that Asian NAs perceived higher levels of supervisory support than other races, whereas U.S.-born NAs reported lower levels of supervisory support than naturalized and residents/aliens. Findings from multivariate analyses indicated that non-Hispanic Asians and Resident/Alien workers reported significantly higher levels of job satisfaction than their counterparts, and the associations were fully mediated by NAs' perceived supervisor support. These findings support prior research that supervisor support is important to improving job satisfaction and contribute to the literature that Asians/Residents/Aliens long-term care workers may be more sensitive to supervisory support and may be more grateful if they received support from supervisors. Managers should be aware of these racial differences and by being supportive they may improve NAs job satisfaction and reduce turnover rates.

THE ROLE OF RELATIONSHIP QUALITY FOR SOLITUDE EXPERIENCES DURING THE PANDEMIC

Yoonseok Choi,¹ Theresa Pauly,² Elizabeth Zambrano Garza,¹ Tiana Broen,¹ Denis Gerstorff,³ and Christiane Hoppmann,⁴ 1. *University of British Columbia, Vancouver, British Columbia, Canada*, 2. *University of Zurich, University of Zurich, Zurich, Switzerland*, 3. *Humboldt University of Berlin, Humboldt University of Berlin, Brandenburg, Germany*, 4. *University of British Columbia, University of British Columbia, British Columbia, Canada*

As time spent at home has significantly increased during the pandemic, reports of household conflict has also risen among people living with others (Usher et al., 2020). One solution to alleviate the potential stress of increased time with others could be carving out time to oneself. The present study investigated how living conditions (e.g., with others vs. alone) are associated with everyday desire for solitude and whether daily solitude experience comes with improved daily emotional well-being in people living with others. Furthermore, it also explored whether relationship quality is associated with solitude experience in a similar manner as living conditions. To do so, we used repeated daily life assessments from a lifespan sample ($N = 215$; M age = 38.3 years, SD age = 17.5; 78 % female) collected during the early pandemic (April to August 2020). Findings indicate that neither living conditions nor relationship quality were

directly associated with daily desire for solitude, but higher relationship well-being was related to low preference for solitude when measured as an individual trait. In addition, relationship quality significantly moderated everyday solitude-affect links: higher relationship quality was related to reduced negative affect during solitude, and conflict was related to increased positive and decreased negative affect on solitude as compared to non-solitude days. The results imply that it is the subjective experience of relationships rather than objective living conditions that shape daily affective quality during solitude.

UNDERSTANDING BARRIERS TO HEALTHCARE ACCESS FOR HEART FAILURE PATIENTS DURING THE COVID-19 PANDEMIC

Hanzhang Xu,¹ Julie Miller,² Roy Thompson,¹ Bradi Granger,³ and Matthew Dupre,² *1. Duke University, Durham, North Carolina, United States, 2. Duke University School of Medicine, Duke University School of Medicine, North Carolina, United States, 3. Duke University, Duke University School of Nursing, North Carolina, United States*

Early outpatient follow-up within two weeks after hospital discharge is an effective strategy for improving transitions of care in older patients with heart failure (HF). However, implementing timely follow-up care for HF patients has been challenging, especially during the COVID-19 pandemic. This convergent mixed-methods study identified patients' barriers to accessing care and ascertained their recommendations for addressing these barriers. We enrolled 264 HF patients admitted to the Duke Heart Center between May 2020 and August 2021. A standardized survey and electronic health records (EHR) were used to collect patients' sociodemographic, psychosocial, behavioral, and clinical data. For patients who reported some difficulty accessing their healthcare (n=30), semi-structured interviews were conducted to understand these barriers. Data were analyzed using rapid analysis techniques. Barriers to accessing care varied across participants, with scheduling an appointment being the most common barrier (12 of the 30 responses). Participants indicated that job-related conflicts, providers' availability, or COVID-19 contributed most to the difficulty in scheduling an appointment. Some participants experienced more difficulties during the pandemic due to fewer appointments available for non-acute and non-COVID-19 related needs. Transportation was another critical barrier, which was often associated with the participants' physical functional status. Participants identified the benefits of using telemedicine to address access to care barriers; however, they shared their concerns that telemedicine visits may not be sufficient to assess their HF conditions. Study findings highlight the need for more continual, tailored, and patient-centered interventions to improve access to care in older HF patients.

USING TAIWANESE UNIVERSAL HEALTH INSURANCE DATA TO ESTIMATE LTC NEEDS WITH MACHINE LEARNING

Kuan-Ming Chen,¹ Chen-Wei Hsiang,² Shiao-Fang Chao,³ Ming-Jen Lin,⁴ Kuan-Ju Tseng,² Yu-Hsuan Chou,⁴ Ji-Lung Hsieh,⁵ and Ya-Mei Chen,⁴ *1. National Bureau of Economic Research, CAMBRIDGE, Massachusetts, United States, 2. National Taiwan University, National Taiwan University, Taipei, Taiwan (Republic of China), 3. National*

Taiwan University, Taipei City, Taiwan (Republic of China), 4. National Taiwan University, Taipei, Taipei, Taiwan (Republic of China), 5. Graduate Institute of Journalism, Taipei City, Taipei, Taiwan (Republic of China)

One of the core issues in long-term care (LTC) policy is the growing imbalance between demand and supply of LTC services due to aging population. To estimate the imbalance and allocate LTC resources, the government regularly conducts surveys. These surveys are expensive given the sample size requirements and imprecise given their subjective nature. This study links the administrative records of the universal health insurance database with LTC program usage records in Taiwan to explore this issue. Machine learning algorithms are used in projecting LTC needs from administrative records. LTC program usage records provide detailed LTC needs information and the amount of service each individual used. In addition, health insurance claim data provides rich health information. Specific LTC needs are predicted for each individual. By further extrapolating to future demographics, long-term LTC needs could be projected. There are several findings in this study. Prediction of difficulties in activities of daily livings (ADL), measured by Barthel index, works best using the Gradient Boosting algorithm. The mean absolute error is 17.67 out of a 0 to 100 scale. In addition to dementia and stroke, diagnosis of pressure ulcer (ICD 10 code: L89) and pneumonia (ICD 10 code: J18) have high predictive power for LTC needs. Prediction of Instrumental ADL (IADL) also performs well with a mean absolute error 1.31. The prediction model suggests high LTC needs and excess demand as the demographics changing. Our study provides a reliable way of using rich information to estimate future LTC needs without conducting additional costly surveys.

VACCINE ACCESS SHRINKS DISPARITIES BETWEEN LONG-TERM CARE AND COMMUNITY RATES OF COVID-19 MORTALITY.

Nicholas Resciniti,¹ Daniel Kaplan,² Joshua Sellner,³ and Matthew Lohman,⁴ *1. University of Southern California, Los Angeles, California, United States, 2. Adelphi University, Cortlandt Manor, New York, United States, 3. Arnold School of Public Health, University of South Carolina, Columbia, South Carolina, United States, 4. University of South Carolina, Columbia, South Carolina, United States*

This longitudinal secondary data analysis examines differences in COVID-19 incidence and mortality among long-term care facility (LTCF) residents with those living in the community in South Carolina (SC) throughout the pandemic, including the time of vaccine availability. Data came from the SC Department of Health and Environmental Control (SCDHEC). Descriptive statistics and trends for cases of infections and deaths were calculated. Cox proportional hazards were used to compare COVID-19 mortality in LTC residents to community dwelling older adults, controlling for age, gender, race, and pre-existing chronic health conditions. Until early January of 2021, significantly greater incidence rates of infection (116.2 per 10,000 per month) and hazard of death after infection (HR=1.83, 95% CI: 1.70-1.98) were experienced among LTC residents as compared to older adults in the community even after statewide mask mandates and visitation guidance. Since vaccine availability, COVID incidence rates among LTC residents fell by half (59.5

per 10,000 per month after vaccines), and the relative hazard of death compared to older adults in the community was diminished (HR=1.44, 95% CI:1.29-1.61). Reducing the gap between LTCF and community-wide infection and mortality rates suggests that vaccination against COVID-19 is correlated with reduced disease spread in the greater community and in LTCF. Results indicate that policies and regulations addressing LTC resident and staff vaccination may effectively protect the most vulnerable older adults and the workforce providing their care while mask mandates and visitation guidance do not.

VIRTUAL CARE FOR CAREGIVERS OF PWD: ADAPTING TO THE NEW NORMAL

Steven Shirk,¹ Maureen O'Connor,² Jaye McLaren,³ Kendra Pugh,² Andrew Nguyen,⁴ Sarah Boucher,² and Lauren Moo,⁵ 1. VA Bedford Healthcare System, Pepperell, Massachusetts, United States, 2. VA Bedford Healthcare System, Bedford, Massachusetts, United States, 3. VA Bedford Healthcare System, VA Bedford Healthcare System, Massachusetts, United States, 4. Boston University, Boston, Massachusetts, United States, 5. VA Bedford Health Care System, Bedford, Massachusetts, United States

Caregivers of persons with dementia (PWD) often experience increases in depression, anxiety, and burden as the disease progresses. In fact, as the PWD's neuropsychiatric symptoms increase and independence in ADLs decrease, caregivers psychological and physical health outcomes worsen. The literature suggests that caregiver interventions that teach specific skills are more beneficial than psychoeducational interventions, particularly regarding the amelioration of the psychological impacts of informal caregiving. However, because of caregiving demands, caregiver's own physical limitations, and competing obligations, it can be difficult to attend caregiver support or education programs outside the home. With the emergence of the COVID-19 pandemic, arranging such interventions became more complex. Therefore, we report on preliminary qualitative outcomes of a study investigating the feasibility and acceptability of converting an in-person, group dementia caregiver education intervention, CARE, to a telehealth platform. We report the findings of two objectives: 1) lessons learned when attempting to convert an in-person group intervention to telehealth and 2) experience and perceived benefit of attending a virtual group from the perspective of the participants of our first two groups. Briefly, our findings demonstrate the strong need for technological support. Participants report positive experience regarding the convenience of attending the group from their home, the benefits of the assigned exercises, and the support they found from other group members. The COVID-19 pandemic has forced many to embrace the virtual option as they adapt to a new normal. There are undoubtedly hurdles to overcome, but there are also advantages to be leveraged.

Session 9515 (Late Breaking Poster)

Late Breaking Poster Session IV

A CLOUD INFRASTRUCTURE FOR LARGE SCALE HEALTH MONITORING IN OLDER ADULT CARE FACILITIES

Yeonsik Noh, and Uchechukwu David,, *University of Massachusetts, Amherst, Massachusetts, United States*

Technology development in the sub-field of older adult care has always been on the back-burner compared to other healthcare areas. But with increasing life expectancy, this is poised to change. With the increasing older adult population, the current older adult care facilities and personnel are struggling to keep up with demand. To address this matter, we proposed a distributed system infrastructure that will enable large-scale monitoring of vital signals and early detection of emergency situations in nursing homes and assisted living communities in this study. The system is mainly comprised of node devices and cloud infrastructure. The node device collects data from multiple users and forwards this data to the cloud service. Communication between the vital-sensing devices on the users and the node device is accomplished using Bluetooth Low-Energy (BLE). The Node device is implemented on a Raspberry Pi Model 3b+ which has built-in BLE capability. A cloud server consists of back-end and front-end components. The back-end handles all the data processing and logical decisions that drive the front-end. The front-end is the interface provided to the end-users, which can monitor all patients in nursing homes at the same time. We examined our system in terms of scalability, real-time operation, cost, and usability and then found that our system provides not only a smart remote monitoring solution that can provide a better aging experience for older adults and their families, but also increase automation in nursing homes leading to a reduction in running cost and an increase in capacity.

A LONGITUDINAL TRAJECTORY OF LONELINESS AND THE COVID-19 PANDEMIC AMONG THE OLDEST-OLD POPULATION

Jimyoung Cho,¹ Shinae Choi,² Gelareh Rahimighazikalayeh,³ Peter Martin,⁴ Melinda Heinz,⁵ and Yeon Ji Ryou,⁴ 1. Baylor Scott & White Health Research Institute, Temple, Texas, United States, 2. The University of Alabama, Tuscaloosa, Alabama, United States, 3. Baylor Scott & White Health Research Institute, Dallas, Texas, United States, 4. Iowa State University, Ames, Iowa, United States, 5. Upper Iowa University, Fayette, Iowa, United States

Loneliness is significantly associated with health and well-being among oldest-old adults. Due to the outbreak of the COVID-19, physical and social distancing policies might elevate loneliness among the oldest-old population. This study examined the trends and changes in the prevalence of feeling lonely using the 2020 HRS COVID-19 module merged to the 15 waves of the HRS RAND longitudinal datasets from 1992 to 2018. A total of 14,371 respondents, including 614 respondents aged 80 years and older were included. Generalized linear models compared age group differences within the 2020 module. Generalized estimating equations assessed the longitudinal change at the individual level and the trend of feeling loneliness among oldest-old adults from 1992 to 2020. Loneliness was assessed with one item of the CES-D scale (i.e., during the past week, felt lonely). After adjusting for demographic characteristics and health, the results showed that oldest-old adults were more likely to feel lonely compared to younger age groups (18% for 80's vs. 14% for 50's) during the early months of the pandemic. A longitudinal trajectory also showed that they feel lonelier than in prior years (19% in 2020 vs. 14% in 2018). However, compared to same-age groups from earlier years, a

significantly lower prevalence of feeling lonely was observed (18% in 2020 vs. 27% in 1994). The results show that the outbreak of the COVID-19 may elevate feeling lonely, but the recent cohorts be less lonely than earlier cohorts. Future research should continue to explore protective factors for loneliness among oldest-old adults.

A QUALITATIVE STUDY OF THE IMPACT OF COVID-19 ON HOSPICE AND HOME-BASED PALLIATIVE CARE IN TAIWAN

YuHsuan (Olivia) Wang,¹ and Susan Enguidanos,² 1. USC, Los Angeles, California, United States, 2. University of Southern California, Los Angeles, California, United States

COVID-19 has had a tremendous impact on individuals and health care, particularly among those with serious illnesses. Although Taiwan initially reported low rates of COVID-19 (20.7 cases per million in 2020), by early 2021 the Alpha variant began spreading in Taiwan, which went into a soft lockdown from May to July. This study aimed to investigate the impact of COVID-19 on Hospice and Home-Based Palliative Care (HBPC) patients, family, and medical team member in Taiwan during different COVID-related time points. From November 2020 to May 2021, we conducted semi-structured interviews with 2 patient, 5 caregivers, and 8 medical team members in the hospice and HBPC setting to elicit their views about the impact of COVID-19 on care. Content analysis was used to guide the analysis of themes. Two researchers independently coded transcripts and met to reconcile codes. Results showed varying impact across the time points. In 2020, patients, caregivers, medical team members felt little impact of COVID-19. However, in 2021, HBPC caregivers reduced the frequency of HBPC visits to lower the household COVID-19 infection risk. Hospice and HBPC team members reported that more caregivers selected HBPC over hospice. They also observed an increase in complicated grief among family survivors following the soft lockdown. The impact of the pandemic on homecare provision increased as prevalence of COVID-19 increased, impacting care and quality of hospice and HBPC. Further research is needed to better understand the impact of the pandemic on the quality of hospice /HBPC and grief experiences.

A TREND OF KOREAN OLDER ADULTS' AWARENESS AS A THREAT TO SOCIETY DURING THE COVID-19 PANDEMIC

SOONHYUNG KWON,¹ Jaesung An,² and Oejin Shin,³ 1. University of Illinois at Urbana-Champaign, Savoy, Illinois, United States, 2. California State University East Bay, Hayward, California, United States, 3. University of Illinois at Urbana Champaign, Savoy, Illinois, United States

Background: Unlike ageism that consists of one's prejudice, stereotype, and discrimination toward older adults, age-based threats are one's negative cognition (Levy, 2001). Previous studies indicated that the younger generation stigmatizes the older generation as unworthy during the COVID-19 pandemic (Meisner, 2021). However, there is no study looking at how older adults perceive themselves as threats to society during this time of the pandemic. Thus, our study aimed to understand the varying trend of older

adults' awareness as a threat to society in association with socio-economic profiles before and during the pandemic. Method: This study included 637 Korean older adults who answered the older generation's threats to society from 2018 to 2020. We used Latent Class Analysis (LCA) to categorize participants into different subgroups that shared distinct patterns of threats to society. Multinomial logistic regression examined how the subgroups in threats to society were associated with socio-demographic characteristics in each year. Results: For three waves, three clusters of threats to society (low, mid, and high) were identified. Although the mid-level of threat remained the same (60% of the sample for three years), the high level of threats has been doubled in 2019 (25%) compared to 2018 (11%) and 2020 (13%). Regarding the associated socio-demographic characteristics with threats to society, those who being female in 2018 and younger age in 2020 were more likely to be associated with mid-level of threats to society. Discussion: Further study needs to identify the relationship between awareness as a threat to society and health outcomes.

ACCELEROMETRY-BASED ASSESSMENT OF PHYSICAL ACTIVITY IN OLDER ADULTS DURING COVID-19 PANDEMIC

Renoa Choudhury,¹ Ladda Thiamwong,² Oscar Garcia,¹ Rui Xie,¹ Jeffrey Stout,¹ and Joon-Hyuk Park,¹ 1. University of Central Florida, Orlando, Florida, United States, 2. College of Nursing, University of Central Florida, Orlando, Florida, United States

COVID-19 pandemic has caused a severely detrimental effect on the physical, psychological, and functional well-being of older adults by forcing them to limit their social activities. This study investigates the amount and intensity of daily physical activity (PA) in older adults, living under the social distancing guidelines during COVID-19 pandemic. In this cross-sectional study, 124 community-dwelling older adults (Age:60–96 years, mean:75±7.14) were recruited via word-of-mouth and key person approach between March 2021-August 2021. Participants completed an online survey on COVID-19 questionnaires and wore an ActiGraph GT9X accelerometer on their non-dominant wrist for consecutive 7 days in free-living conditions. Euclidean Norm Minus One cut-points were used to estimate the total time spent in sedentary behavior (SB), light PA (LPA) and moderate-to-vigorous PA (MVPA). Results showed that, 7% had COVID-positive, 55% perceived moderate severity of COVID in their area, 31% reported fear of COVID, and 14.5% were afraid of losing their life to COVID. On average, participants obtained 12.43±2.1 hours/day of SB, 3.47±1.05 hours/day of LPA and 42.71±29.71 minutes/day of MVPA. MVPA minutes/day was significantly higher (P = 0.006) in participants aged 60-85 years than those aged 85+ years (45.38 minutes/day vs 14.25 minutes/day). When age-adjusted data was compared to pre-COVID-19 studies, we found COVID-19 pandemic had negatively impacted the physical activity level in older adults (29.33% decrease in MVPA and 39.2% increase in SB). These findings can be useful in developing guidelines and/or interventions to promote physical activity and healthy aging among older adults, particularly those in social isolation.

ACCEPTABILITY OF A NEWLY DEVELOPED FINANCIAL PROGRAM FOR CAREGIVERS OF INDIVIDUALS LIVING WITH A CHRONIC ILLNESS

Claire Grant,¹ Sam Fazio,² Monica Moreno,² Beth Kallmyer,² Kerry Lanigan,² and Katherine Judge,³ 1. *Cleveland State University, South Euclid, Ohio, United States*, 2. *Alzheimer's Association, Chicago, Illinois, United States*, 3. *Cleveland State University, Cleveland, Ohio, United States*

Over 40 million informal caregivers provide care to adults aged 50 or older with a chronic illness. In addition to the negative health and well-being impact, caregivers experience financial difficulties including lost income, retirement benefits, future earnings, and unanticipated out-of-pocket costs. Few evidence-informed programs exist to assist caregivers in understanding and managing these financial tasks. This poster presents preliminary acceptability data from 71 caregivers who completed the newly developed Managing Money: A Caregiver's Guide to Finances program. The 60-minute program was delivered online by trained community educators and addressed caregiving costs/impacts; future planning; initiating conversations; avoiding financial abuse/fraud; and identifying needs. Participants ($M = 59.45$, $SD = 11.31$) were 87.32% female with 77.46% self-identified as White, 9.86%, as Black, and 8.45% as Hispanic/Latino. Using a Likert scale (1=strongly disagree to 5=strongly agree), participants indicated the program: 1) identified financial challenges ($M = 4.11$; $SD = 0.73$); 2) provided information for managing money ($M = 3.99$; $SD = 0.64$); 3) content was easy to read/understand ($M = 4.49$; $SD = 0.61$); 4) program length was appropriate ($M = 4.18$; $SD = 0.68$); and 5) activities were helpful ($M = 4.13$; $SD = 0.69$). Participants rated the program as very important ($M = 4.54$; $SD = 0.82$) and would highly recommend ($M = 4.52$; $SD = 0.53$). Results indicated the program was well-received by participants and highly acceptable. Discussion will highlight key program features designed to promote acceptability along with the importance of measuring acceptability for large-scale implementation along with next research steps.

ACCULTURATION MODERATES COGNITIVE PERFORMANCE IN ADULTS AT RISK OF AUTOSOMAL DOMINANT ALZHEIMER'S DISEASE.

Kayla Tureson,¹ Christopher Beam,² and John Ringman,³ 1. *University of Southern California, Los Angeles, California, United States*, 2. *University of Southern California, University of Southern California, California, United States*, 3. *Keck School of Medicine at USC, Keck School of Medicine at USC, California, United States*

Acculturative processes via persistent exposure to a set of cultural practices and behaviors can influence cognitive functioning (Park & Huang, 2010). The impact of acculturation on populations at risk for Alzheimer's disease (AD), however, remains understudied. Persons with or at-risk for early-onset autosomal dominant AD (ADAD) offer a known AD pathogenesis and the opportunity to study whether acculturation moderates their cognitive performance. The present study used a latent variable model to test whether effects of latent cognitive ability on observable cognitive performance depend on acculturation. Participants included 119 adults with or at-risk for ADAD, the majority of whom were of Mexican

origin with various levels of U.S. acculturation. Participants completed the Cognitive Abilities Screening Instrument (CASI) and the Acculturation Rating Scale for Mexican Americans-II (ARMSA-II). Confirmatory factor analysis was used to estimate a latent general cognitive ability factor from nine domains (e.g., attention, abstraction and judgment). The ARMSA-II was used to test whether factor loadings depended on level of acculturation, covarying for mutation status. Results revealed ARMSA-II scores nearly significantly moderated the effects of general cognitive ability on abstraction and judgment ($\lambda = 0.20$, $SE = 0.11$, $p = .070$). Individual differences in general cognitive ability at lower levels of acculturation likely predict lower abstraction and judgment performance. Cognitive assessments may not equally represent true cognitive ability in Mexican-Americans. Although the CASI was developed as a cross-cultural measure of cognitive functioning, caution should be exercised in inferring true cognitive functioning in Mexican-Americans who may not be acculturated to the U.S.

ADVANCE CARE PLANNING AMONG HEALTHCARE PROFESSIONALS DURING COVID-19

Jessica Hahne,¹ and Brian Carpenter,² 1. *Washington University in St. Louis, St. Louis, Missouri, United States*, 2. *Washington University in St. Louis, Saint Louis, Missouri, United States*

The COVID-19 pandemic is bringing healthcare professionals face to face with gravely ill patients in complex clinical situations. Caring for patients experiencing lengthy intubation, heavy sedation, rapid decline, and significant distress at the end of life has the potential to shift the perspectives of healthcare professionals regarding their own end-of-life care. This study explored advance care planning (ACP) among medical professionals and whether COVID-19 experiences altered their healthcare preferences and planning. Ninety-eight professionals (mean age = 45.6, 75% female) completed an online survey about ACP conversations, behavioral intentions to pursue ACP, openness to life-prolonging interventions, and ACP resource needs. ACP conversations were most extensive with spouse/partner (89% had talked about care preferences "some" or "a lot") and to a lesser extent with parents (64%) and other healthcare providers (69%). Two-thirds (67%) of respondents had an ACP conversation since the start of COVID. Among respondents who had not completed ACP documents, 64% had taken some step toward ACP. When asked whether their preferences for life-prolonging medical interventions had changed, 70% reported no change, 16% reported being less open, and 14% reported being more open. A majority (60%) requested resources to help them pursue ACP on their own, although many (42%) were interested in assistance at their workplace. Given that only 37% of our sample had themselves completed an advance directive, our results suggest now may be a critical moment to engage professionals in ACP, considering how their experience during the pandemic has motivated ACP conversations and a reconsideration of preferences.

ADVERSE NEIGHBORHOOD ENVIRONMENTS AND HEALTH BEHAVIORS AMONG OLDER AMERICANS

Yeon Jin Choi, *University of Southern California, Los Angeles, California, United States*

Maintaining healthy lifestyle, including healthy diet and physical activity, in adverse neighborhood environments may be more difficult for older adults because of changes linked to aging, which make them more vulnerable to their environments. This study aims to investigate the association of neighborhood disorder with diet quality and physical activity in a national sample of older Americans. For this study, we used data from the Health and Retirement Study. Neighborhood disorders include vandalism, boarded houses, abandoned cars, demolished houses, trash, litter, or junk, poorly kept communal areas, homeless people, prostitution, winos or junkies, and drug use or drug dealing near residents' housing unit (range: 0-11). Diet quality and physical activity were assessed using the Healthy Eating Index 2015 (HEI-2015; range:0-100) and the metabolic (MET) equivalent activity points (range: 0-31 in this sample). Ordinary least squares regression models were estimated to examine an association between neighborhood disorder, diet quality, and physical activity. Neighborhood disorder was associated with poor diet and physical inactivity. For one additional negative neighborhood feature, HEI-2015 scores and MET-equivalent activity points decreased by 0.55 (95% CI: -1.09, -0.01) and 0.69 (95% CI: -1.05, -0.33). Findings of this study suggest that older adults living in adverse neighborhoods are at a greater risk of poor diet and physical inactivity, which are important risk factors for poor health and chronic diseases. Promoting neighborhood environments and perceived neighborhood safety would increase access to health food, encourage healthy diet and physical activity, and support healthy aging.

AGE DISCRIMINATION AND PERCEIVED WORK ABILITY: THE MEDIATING EFFECT OF SELF-EFFICACY

Hyun Kang,¹ and Hansol Kim,² 1. *George Mason University, Fairfax, Virginia, United States*, 2. *National Rehabilitation Research & Training Center on Family Support, Pittsburgh, Pennsylvania, United States*

As the number of older workers in the U.S. workforce increases, perceived work ability, which indicates a worker's capacity to perform job-related tasks or to remain employed, becomes increasingly important. However, age discrimination may undermine the ability of older adults to remain active in the workplace as it poses a significant barrier to their work ability. The purpose of this study was to examine how age discrimination affects perceived work ability among older workers. We also evaluated the role of self-efficacy as a potential mediator between age discrimination and perceived work ability. Self-efficacy can contribute to older adults' productive aging since it helps them view age-related situations more positively. Using 2,011 respondents (aged 50+) data from the 2018 Health and Retirement Study, structural equation modeling analysis was conducted. Our findings indicated that age discrimination had a direct negative effect on perceived work ability ($B = -.230, p < .001$). Older workers who experienced more age discrimination were more likely to have low levels of perceived work ability. The indirect effect of self-efficacy ($B = -.177; 95\% \text{ CI} = -.240, -.135$) was significant. Older workers who experienced more age discrimination were more likely to have low levels of self-efficacy, and this relationship led to lower levels of perceived work ability. These results suggest that greater efforts are

required to reduce age discrimination and its negative consequence on perceived work ability and self-efficacy among older workers. Furthermore, age discrimination laws should be more explicitly enforced in the policy direction for older workers.

AGE-RELATED ETHNIC DIFFERENCES IN SELF-REPORTED HAND FUNCTION

Ejlal Bin Mulayh,¹ Rachel Logue,² and Susan Brown,² 1.

University of Michigan, University of Michigan, Michigan, United States, 2. *University of Michigan, Ann Arbor, Michigan, United States*

Racial/ethnic differences in the prevalence of disability based on self-reported activities of daily living (ADLs) exist in older Americans, particularly in Hispanic adults. Such studies have relied on large data sets in which disability is measured across a broad range of functional tasks. While useful in generating a global measure of disability, it precludes an ability to differentiate, for example, deficits in upper versus lower extremity function which can provide useful information in targeting therapeutic interventions. Despite known age-related declines in hand function and concomitant ADLs, racial/ethnic differences in hand-related ADL limitations have not been addressed. Using 2011-2018 data from the National Health and Nutrition Examination Survey (NHANES), we identified 3,189 non-Hispanic White and Hispanic adults aged 65 and older, and classified responses based on perceived difficulty to five self-reported tasks requiring hand dexterity. Compared to non-Hispanic Whites, Hispanic males reported 2.2 times higher rates of difficulty for dressing tasks ($p < 0.01$) and 3.3 times higher rates for difficulties preparing meals ($p < 0.01$). Similar rates of difficulty were also observed in females. Additionally, Hispanic females reported 4.6 times higher rates of difficulty in tasks requiring grasping small objects ($p < 0.01$). Deficits in hand function are often under-reported in older adults despite the role of dexterity in maintaining functional independence. The results presented here indicate that difficulties in hand-related ADLs are more prevalent in the Hispanic population and warrant greater attention in health care settings. Future work will include identifying factors contributing to these observed differences in self-reported difficulties in hand-related ADLs.

ALLOSTATIC LOAD FOLLOWING SHORT-TERM INTERVENTION: COGNITION IN OLDER HYPERTENSIVE ADULTS

Anthony Cirilo,¹ Jordan Kohn,² Gavrila Ang,² Meredith Pung,² Emily Troyer,² Christopher Pruitt,² Laura Redwine,³ and Suzi Hong,² 1. *UCSD MADURA R25 Advancing Diversity in Aging Research Program, San Diego, California, United States*, 2. *University of California, San Diego, San Diego, California, United States*, 3. *University of South Florida, Tampa, Florida, United States*

Allostatic load (AL), a measure of cumulative effect of prolonged stressors across physiological systems, is consistently associated with adverse health outcomes. Greater AL is correlated with functional decline in aging, but effects of behavioral interventions, such as Tai Chi (TC), on AL in older adults in a short-term is unknown. To investigate the effects of TC practice on AL and cognitive function

and an AL-cognition relationship, older adults (60-95 years) with hypertension were recruited and randomly assigned to 12-week TC or Healthy Aging Practice-centered Education (HAP-E) classes. The AL index (ALI) included: SBP and DBP; urinary epinephrine and norepinephrine; plasma inflammatory biomarkers (CRP, IL-6); metabolic biomarkers (HDL, total cholesterol, triglycerides, HbA1c); and BMI. The Montreal Cognitive Assessment (MoCA) was administered to assess cognitive function. Generalized linear mixed-effects models, adjusted for age, race, education, and intervention attendance, was used. Pre- and post-intervention ALI did not change significantly in TC (2.61 (1.48) to 2.76 (1.62)) or HAP-E (2.84 (1.61) to 2.66 (1.86)). High ALI was associated with lower MoCA scores, indicating poorer cognitive performance (IRR=0.96; 95% CI: 0.93-0.98; $p=0.002$) across the time points. Of note, the MoCA scores did not significantly change across time (25.4 (3.2) to 26.0 (3.0)). 12-week TC or HAP-E interventions did not lead to a significant change in ALI or cognitive performance in our population. However, our findings show greater AL theoretically attributed to chronic stress is associated with cognitive functioning in older adults consistently over about 4 months.

ANALYZING THE SPECIFIC ROLE OF COGNITIVE FUNCTIONING ON SUCCESSFUL AGING

Neyda Ma. Mendoza-Ruvalcaba,¹

Elva Dolores Arias-Merino,² Maria Elena Flores-Villavicencio,³ and Maria Elena Rodriguez-Diaz,³

1. *Universidad de Guadalajara CUTONALA, Guadalajara, Jalisco, Mexico*, 2. *Universidad de Guadalajara, Zapopan, Jalisco, Jalisco, Mexico*, 3. *Universidad de Guadalajara, Universidad de Guadalajara, Jalisco, Mexico*

Introduction The cognitive functioning, as a general measure, is a criterion commonly used to define and operationalize successful aging. (Project-Conacyt-256589) The aim of this study is to analyze specific domains of cognitive function and its relationship with the successful aging in older adults. **Methods** Population based, random sample included $n=453$ community-dwelling older adults 60-years and older (mean age=72.51, SD=8.11 years, 59.4% women). Cognitive functioning was assessed by a comprehensive battery including working memory (Digit Span Backward WAIS-IV), episodic memory, meta-memory (self-report), processing speed (Symbol Digit WAIS-IV), attention (TMT-A), executive functioning (TMT-B), learning potential (RAVLT), language (FAS), visuospatial skills (Block Design WAIS-IV). Successful aging was operationalized as no important disease, no disability, physical functioning, cognitive functioning, and being actively engaged. Sociodemographic and health data were also asked. Data were analyzed in SPSSv24, MANOVAs and size effects were calculated. Results In total 11.2% were successful agers and 11.4% had Mild Cognitive impairment. Global cognitive functioning was significantly related to the achievement of successful aging criteria. Cognitive functioning had a significant effect on successful aging, specifically executive functions ($F=1.07, p=.000$) explained 32.7% of the variance, attention explained 29.8% ($F=1.19, p=.006$), processing-speed 21% ($F=1.38, p=.000$), and learning potential 21.5% ($F=1.12, p=.005$). Language, visuospatial skills, working memory and meta-memory had a very small effect. **Conclusion** Knowledge generated by this study reveals the

specific role of cognitive domains on successful aging, and sets a scenario to promote successful aging, through alternatives centered in the improvement of cognition in the older adults.

AS WOMEN LIVE LONGER, WHAT DO THEY NEED MOST?

Jennifer Yahner,¹ and Jeanette Hussemann,² 1. *Urban Institute, Washington, District of Columbia, United States*, 2. *NORC at the University of Chicago, Chicago, Illinois, United States*

Women in the United States can live into their 80s, 90s, and even 100s—outliving men nearly five years on average. Over the next four decades, the number of women aged 85 years and older will nearly triple in size. Many will live alone and in poverty, with increasingly fewer supports on which to rely as they age. Although women can spend their lives caring for children, partners, and parents, often while working multiple jobs, as they grow older, many find their physical, emotional, and financial needs cannot be met. Using data recently collected for the Urban Institute's EMPOWER: Building Late-Life Resilience study, with funding from the National Institute of Justice, we examine the needs of low-income women aged 85 years and older ($N=35$) living alone in Arizona communities. We explore issues of home safety perceptions and social isolation and study their relationship to women's physical, emotional, and financial wellbeing.

ASSISTED LIVING ADMINISTRATORS' MENTAL AND EMOTIONAL HEALTH DURING THE COVID-19 PANDEMIC

Ozcan Tunalilar,¹ Jaclyn Winfree,¹ Jason Kyler-Yano,¹ Serena Hasworth,² and Paula Carder,³ 1. *Portland State University, Portland, Oregon, United States*, 2. *Portland State University, Portland State University, Oregon, United States*, 3. *OHSU-PSU School of Public Health, Portland, Oregon, United States*

Little is known about assisted living (AL) administrators' mental and emotional health, particularly during a global pandemic in which most of their residents are highly vulnerable to infection, hospitalization, and death. Considering that administrator turnover and burnout have been associated with negative outcomes such as decreased quality of resident care, low staff morale, and reduced financial solvency, this study examined how AL administrators described their mental and emotional state throughout the first year of the COVID-19 pandemic. Using thematic analysis, our team coded 18 qualitative interviews conducted from May-August 2021. The themes included declining physical health due to stress, feelings of inadequacy and self-doubt, and increased burnout. Many administrators described increased staffing challenges as directly impacting their daily stress levels. Some administrators described feeling guilty and doubting their interpretation or implementation of regulations, particularly in incidents that further distanced residents from peers and loved ones. A few administrators described their disposition or personality changing due to what they experienced during the pandemic. One administrator stated, "I'm not an anxiety person, but I feel anxiety about a lot of things. In fact, my doctor has talked to me about starting some medications to help with that." Multiple administrators

made comments such as, “I don't know that there could be a more stressful position than executive director of assisted living...the COVID pandemic reinforced that. This is rough.” Understanding AL administrators' mental and emotional health during a public health crisis allows for understanding, supporting, and retaining critical leaders in long-term care communities.

ASSOCIATION BETWEEN LENGTH OF RESIDENCE IN THE U.S. AND INSURANCE COVERAGE WITHIN U.S. CHINESE OLDER ADULTS

Natalie Tuseth,¹ XinQi Dong,² Stephanie Bergren,³ and Michael Eng,⁴ 1. *Rutgers Institute for Health, Health Care Policy and Aging Research, New Brunswick, New Jersey, United States*, 2. *Rutgers, New Brunswick, New Jersey, United States*, 3. *Rutgers University, New Brunswick, New Jersey, United States*, 4. *NYU Grossman School of Medicine, New York City, New York, United States*

Barriers to affordable insurance may worsen disparities among underserved populations. Immigrants with <5 years of residence are not eligible for Medicare and Medicaid and are potentially without affordable alternatives. This study aims to look at the relationship between length of residence in the U.S. and insurance coverage within U.S. Chinese older adults ages 65+. This study used data from a representative sample of 2,365 community-dwelling U.S. Chinese older adults age 65+. The association between length in the U.S. (<5, 6-10, 10+) and insurance status was analyzed using chi squared test and logistic regressions. Within this sample, 58 (2.78%) participants had coverage outside Medicare and Medicaid, with 279 participants reporting no coverage. The vast majority of participants living in the U.S. <5 years had no insurance (81.48%). In a fully adjusted model, participants who were older and female were positively associated with having insurance coverage (OR:1.11 [1.07,1.15] and OR:1.29 [0.88,1.90]). Conversely, both living in the U.S. <5 years (OR:0.009 [0.006, 0.014]), and between 5-10 years (OR:1.20 [0.13,0.30]) were negatively associated with insurance coverage. When including coverage outside of Medicaid and Medicare, residence <5 years and 5-10 years were still negatively associated with insurance coverage ((OR:0.13 [0.009,0.02]), and (OR:0.19 [0.13,0.30])). Vulnerable populations such as older immigrants may not have access to insurance outside of public options, making a 5-year waiting period an additional barrier to quality health care.

ASSOCIATION OF DEMENTIA SEVERITY AND ASSISTANCES NEEDS ON MISSED HOME HEALTH VISITS.

Sara Knox,¹ Brian Downer,² Allen Haas,² and Kenneth Ottenbacher,² 1. *Medical University of South Carolina, Charleston, South Carolina, United States*, 2. *University of Texas Medical Branch, Galveston, Texas, United States*

Individuals with Alzheimer's Disease and Related Dementias (ADRD) experience barriers to accessing health care services, including services provided during home health care. Additionally, it is not clear if people with ADRD who are admitted to home health care receive all the services needed to maximize their outcomes. Barriers to receiving the optimal care can include the presence or absence of a care

giver, behavioral and psychological symptoms of ADRD, or therapists lacking the skills needed to effectively engage patients in therapy sessions. These barriers may vary dependent on the patient's ADRD severity. The purpose of this study was to examine the relationship between dementia severity and early discharge from home health care. This was a retrospective study of 142,376 Medicare beneficiaries with ADRD who received home health care between October 2016 and September 2017. Early discharge was defined as discharge from home health with more than two missed visits. Early discharge rates were calculated, and multilevel logistic regression was used to estimate the relative risk (RR) of early discharge, by dementia severity level, adjusted for patient and clinical characteristics. 10.4% of beneficiaries had an early discharge. Dementia severity was not associated with risk of early discharge. However, level of medication assistance needed was found to be associated with risk of early discharge (RR=0.849; 95% CI 0.759 - 0.948). Medication management may impact a patient's ability to adequately attend and engage in home health therapy services. Further studies are needed to better delineate the interaction between medication management and early discharge.

ASSOCIATIONS BETWEEN PACS SYMPTOMS AND RISK FACTORS AMONG LONG HAULERS IN THE RUTGERS POST-COVID RECOVERY PROGRAM

Alice Dawson,¹ and William Hu,² 1. *Rutgers University-New Brunswick, New Brunswick, New Jersey, United States*, 2. *Rutgers University, New Brunswick, New Jersey, United States*

At least 2/3 of people with mild to moderate COVID-19 infection will experience long-haul COVID symptoms that persist for weeks or months, however, risk factors that modify the likelihood that one develops these symptoms are unknown. Patients referred to the Post-COVID Recovery Program at Rutgers in New Brunswick (n= 108) through primary care referral or self-submitted online request and experiencing a wide variety of Post-Acute COVID-19 Syndrome (PACS) symptoms were stratified by those without self-reported cognitive complaints (n=54), those with self-reported cognitive complaints who scored well on cognitive testing (n=29), and those with self-reported cognitive complaints who scored poorly on cognitive testing (n=25). Comparisons between groups were made using ANOVAs and Chi Squared: for COVID-19 disease severity, COVID-19 disease treatment, comorbid COVID-19 symptoms during infection, comorbid PACS symptoms post-infection, pre-existing health conditions, levels of depression and anxiety, level of fatigue, and social determinants of health (access to healthcare, economic stability, housing stability). Preliminary analyses indicated that whereas people without complaints were normally distributed according to age (p>0.200 for Kolmogorov-Smirnov test), people with complaints and deficits were skewed towards the older age group (p<0.001 for K-S test) suggesting age to be a risk factor for cognitive impairment in PACS. Participants that reported cognitive complaints also reported increased symptoms of depression, anxiety, and fatigue, compared to participants without cognitive complaints. These data provide insight into associations between PACS symptoms and risk factors relevant in understanding this novel disease.

ASSOCIATIONS OF ADVERSE CHILDHOOD EXPERIENCES WITH EXECUTIVE FUNCTION AND BRAIN-DERIVED NEUROTROPHIC FACTOR

Cindy Tsotsoros,¹ Madison Stout,² and Misty Hawkins,²
 1. Oklahoma State University, Stillwater, Oklahoma, United States, 2. Oklahoma State University, Oklahoma State University, Oklahoma, United States

Adverse childhood experiences (ACEs) may predict markers of neurocognitive performance (i.e., executive function; EF) and brain health/plasticity (i.e., brain-derived neurotrophic factor; BDNF). This pilot examined the magnitude of effects between: 1) ACEs and EF performance, 2) ACEs and BDNF levels, and 3) EF performance and BDNF levels. We hypothesize that higher ACEs will be associated with poorer EF scores and lower BDNF levels and that lower EF scores will be associated with lower BDNF levels. Given the pilot nature of the study, an emphasis is placed on effect size vs. significance. Participants were 36 middle-aged women enrolled in the NICE SPACES trial (age=31.4 years, BMI=34.2, racially minoritized=37.9%). ACEs were quantified using the 10-item Adverse Childhood Experiences Scale. EF was measured using the fluid cognition composite from the NIH Toolbox – Cognition Battery. BDNF was estimated using proBDNF levels estimated from serum collected via venipuncture. Higher ACEs levels were not directly associated with EF scores ($b = 0.03$, $p = .854$); but did show a meaningful negative beta coefficient with BDNF levels ($b = -0.34$, $p = .053$). EF scores and BDNF showed a positive coefficient that did not reach significance ($b = .26$, $p = .122$). In a modest pilot of middle-age women, higher ACEs were associated with lower BDNF, indicating greater adversity in childhood is linked to lower neurotrophins levels in adulthood. The lower BDNF levels may help explain poorer performance on cognitive tasks. Larger follow-up studies in more powered samples are warranted given the size of detected coefficients.

ATTACHMENT STYLE DIFFERENCES IN THE AFFECTIVE EXPERIENCE OF CHRONIC PAIN IN OSTEOARTHRITIS

Katherine Cheesman,¹ Patricia Parmelee,² and Dylan Smith,³
 1. The University of Alabama, Tuscaloosa, Alabama, United States, 2. University of Alabama, University of Alabama, Alabama, United States, 3. Stony Brook University, Stony Brook University, New York, United States

Objective. To examine the role of adult attachment style in the daily affective experiences of older adults with physician-confirmed knee osteoarthritis (OA). Methods. As part of a larger study of racial/ethnic differences in everyday quality of life with OA, 292 persons over the age of 50 completed a baseline interview including the Revised Adult Attachment Scale (RAAS; Collins, 1996). Dimensional RAAS attachment scores were coded into the secure, preoccupied, fearful, and dismissing groups (Bartholomew & Horowitz, 1991). Positive affect (PA), negative affect (NA), and pain were assessed using an experience sampling methodology consisting of 4 daily phone calls over 7 days. These analyses used ANCOVAs to examine 28-call means and SDs for PA, NA, and pain. Results. After controlling for demographics, results indicated significant group differences in average PA, NA, and pain. Pairwise comparisons indicated that participants endorsing a stable attachment style reported significantly

more PA and less NA than those with a fearful attachment style. Group differences for pain were marginal and less clear cut. Significant differences also emerged for variability of NA and pain. Individuals with a secure attachment style were significantly less variable in NA than those in the fearful and preoccupied groups. For pain variability, the preoccupied group showed more variability than those with secure or dismissive styles. Implications. Results contribute to a growing understanding of how individual attachment style may underlie the day-to-day affective experience of chronic pain. (Supported by R01-AG041655, D. Smith and P. Parmelee, PIs.)

BEST PRACTICES FOR LIVING LABS WHEN STUDYING OLDER ADULTS LIVING IN RURAL COMMUNITIES

Ashley Nakagawa,¹ Shannon Freeman,² Alanna Koopmans,³ Chris Ross,⁴ and Richard McAloney,² 1. University of Northern British Columbia, Honolulu, Hawaii, United States, 2. University of Northern British Columbia, Prince George, British Columbia, Canada, 3. UNBC, University of Northern British Columbia, British Columbia, Canada, 4. University of Northern British Columbia, University of Northern British Columbia, British Columbia, Canada

There are two core concepts that make living labs distinguishable: involvement of users as co-creators and evaluation in a real-world setting. Living labs increase the potential for product acceptance and adoption due to testing and tailoring with target users. Currently, there is a lack of a universally accepted guideline for best practices. The objective of this review is to identify the best practices of living labs that can be recognized by the scientific community and followed in future labs. A 5-stage scoping review, following Arksey and O'Malley's (2005) framework, was used to map out the coverage of different aspects of living lab methodology. A systematic search for articles involving living lab framework and older adults published between 2016-2021, was conducted in seven databases. Nine articles were included after review, the majority of which were published in health journals and were from Italy and the United States. An overview of consistent user involvement in the innovation process, real-world testing vs. laboratory testing, and participant scope findings will be shared. Multiple rounds of user feedback, real-world testing, and a small but diverse participant group were the most successful in increasing positive sentiments about the products tested in a living lab environment. The lack of published articles on living lab frameworks studying older adults indicate a gap in the literature. Creating a universally accepted definition for living labs and guidelines for best practices will allow for scientific validity and comparisons of studies and may increase the use and popularity of living labs.

BREAST CANCER SCREENING AND MOBILE WEB APP INTERVENTION: PERCEPTIONS, KNOWLEDGE, AND NEEDS AMONG NATIVE WOMEN

Soonhee Roh,¹ and Yeon-Shim Lee,² 1. University of South Dakota, Sioux Falls., South Dakota, United States, 2. San Francisco State University, San Francisco, California, United States

American Indian (AI) women have the highest breast cancer mortality and lowest breast cancer screening rates in

the U.S. The present study, in collaboration with the Yankton Sioux Tribe (YST) in South Dakota, sought to (1) identify the general public/professionals' knowledge, attitudes, and needs for a mobile web app for breast cancer screening (wMammogram) intervention, and (2) inform development of the wMammogram intervention to improve Breast Cancer screening among YST women. Following a community-based participatory research approach, two focus groups were conducted in October 2020 with a total of 22 YST women aged 40-70 years, including 17 elderly women. Each group consisted of 11 community leaders, members, healthcare professionals. Qualitative analysis was conducted using grounded theory. Participants in both groups were generally favorable toward the wMammogram intervention, and noted a potential health benefit, particularly for women in their 50s to 60s. Key areas identified by participants for intervention include: (1) needs for better knowledge of breast cancer, screening, and prevention/early detection, (2) culturally tailored educational materials rooted in AI cultural values and beliefs (e.g., holistic wellness approach, Native lifestyles), (3) barriers (e.g., fear), (4) motivators (e.g., reminders), and (5) suggestions for acceptability (e.g., content and structure of messages). These results suggest that the wMammogram intervention, which is culturally tailored and addresses the community's concerns, can be a feasible, acceptable, and effective tool to promote breast cancer screening among YST women. The results informed the development of an innovative health intervention to help reduce health disparities experienced in Indian Country.

CAREGIVING FOR PERSONS LIVING WITH DEMENTIA IN THE NEW NORMAL: FAMILY CAREGIVER'S PERSPECTIVE.

Priyanka Shrestha,¹ Donna Fick,² Marie Boltz,² Susan Loeb,³ and Andrew High,³ 1. *Betty Irene Moore School of Nursing (UC-DAVIS Health)*, 2. *Pennsylvania State University, University Park, Pennsylvania, United States*, 3. *Pennsylvania State University, State College, Pennsylvania, United States*

Persons living with dementia (PLWD) are at increased risk for COVID-19 and associated poor outcomes, including: incident delirium, hospitalization, severe symptoms, intensive care admission, and even death. PLWD are likely to rely on family caregivers to maintain their health and well-being in the community. Under normal circumstances, caregiving can be stressful and complex, and the COVID-19 pandemic has the potential to change and exacerbate the stresses of family caregiving. As a part of a larger study using descriptive qualitative methodology to explore the family caregiver understanding and experiences related to delirium in caring for a person with dementia, 14 participants (age \bar{x} =67, SD=13.8) were asked about the impact of COVID-19 on their caregiving for PLWD. Thematic analysis of the transcribed interviews using Dedoose generated four overarching themes associated with the family caregiver's perspective of changes in caregiving during the COVID-19 pandemic: 1) Cautious of COVID-19 exposure, 2) We can't go in, 3) Feeling of isolation for both the PLWD and caregiver, and 4) Six-foot distance. The current study highlights the importance of understanding the needs of PLWD during a pandemic based upon the perspective of their family caregivers and will

inform the development of ways to safely incorporate family caregivers in the interdisciplinary care team. Caregivers are integral to the care of PLWD across settings of care and should be partners even during a pandemic. Solutions for care include integrating technology for individualized approaches. Finally, future areas for research will be discussed.

CAREGIVING, LONELINESS, AND STRESS: THE ROLE OF COVID-19

Sumaiyah Syed,¹ Iris Yang,² and Stephanie Wilson,² 1. *Southern Methodist University, Dallas, Texas, United States*, 2. *Southern Methodist University, DALLAS, Texas, United States*

According to many prior studies, informal caregivers are at risk for heightened loneliness and distress. Moreover, the COVID-19 pandemic has introduced new challenges that may be accentuated among caregivers. This study examined caregiving frequency and its relation to loneliness, perceived stress, and negative affect during the COVID-19 pandemic. We then investigated the moderating roles of COVID-19 concerns and impacts, anticipating magnified effects among caregivers. Participants included respondents from the Health and Retirement Study (HRS) COVID-19 project sample (n=2108, mean age=69) who reported their caregiving frequency, general concern about COVID-19, related concerns about family members' health, and social disruptions caused by the pandemic. Controlling for age, gender, and health status, daily caregivers reported significantly greater distress during COVID-19 compared to non-caregivers (p=.036). Higher levels of concern about family members' health during COVID-19 was significantly associated with greater loneliness among daily caregivers (p = .009), but not among non-caregivers, such that daily caregivers with greater concerns had the highest levels of loneliness. On the other hand, unexpectedly, daily caregivers who experienced fewer social disruptions due to the pandemic reported higher levels of loneliness (p = .002); however, the association was null for non-caregivers. Findings suggest that daily caregivers may be particularly vulnerable to greater loneliness and stress during the COVID-19 pandemic. These experiences may exacerbate existing mental health disparities for those providing daily care.

COHORT DIFFERENCES IN DAILY LIFE: OLDER ADULTS HAVE HIGHER AFFECT VARIABILITY THAN 18 YEARS AGO

Johanna Drewelies,¹ and Rachel Koffer,² 1. *Humboldt University of Berlin, Humboldt University Berlin, Berlin, Germany*, 2. *Arizona State University, Phoenix, Arizona, United States*

Lifespan psychological and life course sociological perspectives have long acknowledged that individual functioning is shaped by historical and socio-cultural contexts. Secular increases favoring later-born cohorts are widely documented for general well-being (among older adults). However, little is known about secular trends in short-term fluctuations in daily affective well-being and whether historical changes have occurred in young, middle-aged, and older adults alike. To examine these questions, we compared data from two independent national samples of the NSDE survey obtained 18 years apart (1995/96 vs. 2013/14)

and identified case-matched cohorts (per cohort, $n = 782$, aged = 23–75 years) based on age and gender. We additionally examine the role of economic and health resources for cohort differences in affective variability. Results revealed that later-born cohorts report higher variability in daily negative affect than did those 18 years ago. In contrast, no cohort differences emerged in variability in daily positive affect. We conclude from our national US sample that secular trends in affect variability do not generalize unanimously to different timescales across adulthood. We discuss possible underlying mechanisms and practical implications.

CONFIRMING A DROSOPHILA MELANOGASTER MODEL OF HUNTINGTIN AGGREGATION

Akosua Biritwum,¹ Simon Levy,² Bess Frost,² and Atanu Duttaroy,¹ 1. *Howard University, Washington, District of Columbia, United States*, 2. *UT Health San Antonio, San Antonio, Texas, United States*

For decades, doctors, psychologists, and psychiatrists alike have struggled to treat the symptomatic effects of Huntington's disease. Huntington's disease is an autosomal dominant brain disease that results in the deterioration of a person's physical and mental state. Once a person inherits the disease, they end up dying from it more often than not. At present, there are 41,000 Americans with symptomatic Huntington's disease, and 200,000 more are currently at-risk of inheriting the disease. Given its 50/50 chance of inheritance, there seems to be no end in sight to this degenerative ailment. My research study, however, will show that with a more robust approach, finding a cure for this disease is possible. Ultimately, the aim of this project was to test an already established model in *Drosophila melanogaster* regarding the "huntingtin" protein responsible for Huntington's disease. This was achieved by first demonstrating that the flies which were modified to produce huntingtin could, in fact, produce the protein. Secondly, an experimental process was created to configure a system through which the amount of protein produced by each fly could be quantified. This quantification was vital in creating a baseline that would allow for the identification of potential therapeutic treatments in the future. In short, by establishing a quantifiable model for huntingtin, this study will pave the way to new insights on huntingtin aggregation and the identification of possible treatments for Huntington's disease in the future.

CONVERGENT AND CONSTRUCT VALIDITY OF A CONVERSATION DIFFICULTIES OUTCOME MEASURE IN PRIMARY PROGRESSIVE APHASIA

Haylie Santos,¹ Nathan Gill,² Elizabeth Salley,² Hui Zhang,² Emily Rogalski,² and Angela Roberts,¹

1. *Northwestern University, Evanston, Illinois, United States*,
2. *Northwestern University, Chicago, Illinois, United States*

Cognition and language changes, and their impacts on functional communication, are central to many dementias. Thus, functional communication, including conversation difficulties, is an important endpoint for clinical trials. To develop robust outcomes in primary progressive aphasia (PPA), a dementia characterized by communication impairments, we examined the convergent and construct validity of the Perception of Conversation Difficulties-Dementia Alzheimer's Type (PCI-DAT; Orange et al., 2009). The

PCI-DAT is a care partner reported measure of conversation difficulties. Eighty-two care partners with a mean age of 64.8 years ($SD=10.61$; 85% spouses, 5% adult children, 10% friends/siblings) whose mean relationship duration to the person with PPA was 39.1 ($SD=15.1$) years completed the study. Pearson's correlation indicated a significant, modest correlation ($r=-0.54$, $p<0.0001$) between the PCI-DAT Perception of Conversation Difficulties subscale and the Communication Effectiveness Index (Lomas et al., 1989) suggesting strong convergent validity. A Rasch analysis conducted on the same PCI-DAT subscale showed high person (0.92) and item (0.95) reliability indicating a robust overall scale structure that adequately evaluates various levels of conversation difficulty severity in PPA. Six items (27%) had minor 'fit' issues (defined by Wright and Linacre, 1994 as having infit statistics < 0.6 or > 1.4) relative to the underlying construct. Results suggest strong convergent and construct validity of the PCI-DAT in PPA and indicate items that will benefit from further development. Overall, our results suggest that the PCI-DAT holds promise for use as a functional communication endpoint in PPA clinical trials. Data for all five PCI-DAT subscales will be presented.

COPING WITH THE SUBJECTIVE IMPACT OF COVID-19 AMONG OLDER ADULTS IN PUERTO RICO

David Camacho,¹ Yamile Marti,² Sunghwan Cho,³ Thomas Buckley,⁴ Julia Vazquez,⁵ Denise Burnette,⁶ and Humberto Fabelo,⁶ 1. *University of Maryland Baltimore, Baltimore, Maryland, United States*, 2. *Columbia University, Columbia University School of Social Work, New York, United States*, 3. *VCU, Richmond, Virginia, United States*, 4. *Virginia Commonwealth University, NORFOLK, Virginia, United States*, 5. *University of Maryland, University of Maryland, Baltimore, Maryland, United States*, 6. *Virginia Commonwealth University, Virginia Commonwealth University, Virginia, United States*

The COVID-19 pandemic poses serious physical and mental health risks for older adults worldwide. To develop culturally and contextually congruent services to mitigate these risks requires understanding their stress and coping processes, which remain understudied in Latin America. This study examines qualitative data from 51 adults aged 60 and over who participated in an ongoing study of older Puerto Ricans' knowledge, attitudes, and practices about COVID-19. Trained interviewers collected the data by telephone from January to August, 2021. Two-thirds of participants were female, 60% had less than high school education and 90% had poverty-level incomes. Drawing on Lazarus and Folkman's Stress and Coping Theory, we conducted a thematic analysis of responses to open-ended questions about the nature and extent of COVID-related stressors, stress management, and meanings and guidance they had gleaned from their experience. Participants perceived the pandemic as an added threat to ongoing chronic stressors (e.g., Hurricane Maria, poverty, political instability); disruptions in daily routines, family cohesion, and grief and loss processes; and increased isolation and loneliness. They reported using cognitive, behavioral, socioemotional and spiritual coping, including positive thinking, keeping occupied, relaxation, religious practices and, in a few cases, social media. Participants highlighted a revitalized appreciation for emotional qualities of

relationships, freedom and life in general. Consistent with our guiding theory, cultural, contextual, religious, and socio-political factors shaped their appraisals of stress and their coping strategies. Future research should examine how these practices relate to health outcomes and quality of life and how they can inform effective, appropriate interventions.

COVID-19 SILVER LININGS - EXPERIENCE OF SPOUSAL CAREGIVERS OF PERSONS WITH DEMENTIA ENGAGED IN SUPPORT PROGRAM

Andrew Nguyen,¹ Elizabeth Stevenson,² Mary Mittelman,³ Roscoe Nicholson,⁴ Tiffany Donley,⁵ Rebecca Salant,⁶ Steven Shirk,⁷ and Maureen O'Connor,¹ 1. *Boston University School of Medicine, Boston, Massachusetts, United States*, 2. *NYU Langone Health, New York, New York, United States*, 3. *NYU Langone Health NYU Grossman School of Medicine, NYU Grossman School of Medicine, New York, United States*, 4. *University of Chicago, Evanston, Illinois, United States*, 5. *NYU School of Medicine, New York, New York, United States*, 6. *NYU School of Medicine, NYU School of Medicine New York City, New York, United States*, 7. *Bedford Veterans Administration Medical Center, Bedford, Massachusetts, United States*

Caring for a person with dementia (PWD) has been consistently associated with negative effects on health, including increases in caregiver depression, anxiety, and burden. Emerging studies have shown that the COVID-19 pandemic has increased these factors due to reported increases in caregiver workload and cognitive and behavioral symptoms of the PWD. We interviewed 10 spousal caregivers of PWD from the NYU Langone Alzheimer's Disease and Related Dementias Family Support Program in Summer 2020 during the COVID-19 pandemic in order to gain feedback about their experiences during the pandemic and the transition from in-person to videoconferencing that could be used to improve services and support. Caregivers discussed the challenges faced during the pandemic but also the unique opportunities the situation presented. We report here on those positive aspects of COVID-19 from the perspective of the caregivers we interviewed. Methods: Interviews of caregivers residing with their spouses in the New York City area were conducted via videoconferencing, transcribed, deidentified, and analyzed using framework analysis methods. Results: We found that caregivers reported some positive reaction to videoconferencing that included increased support group cohesion, increased convenience, feeling less obligated to participate in events, and new opportunities for social contact. Participants also discussed positive inter-couple relationship changes such as increased quality time spent together. Our findings resonate with a body of literature focused on understanding the positive aspects of caregiving. Understanding the full presentation of the caregiver experience, including both positive and negative aspects, is important for developing interventions and resources for this unique group.

COVID-19 VACCINES IN SKILLED NURSING FACILITIES: RECURRING INTERVIEWS WITH ADMINISTRATORS

Amy Meehan,¹ Joan Brazier,¹ Renee Shield,¹ Caroline Madrigal,² and Emily Gadbois,¹ 1. *Brown*

University, Providence, Rhode Island, United States, 2. *Providence VA Medical Center, Providence VA Medical Center, Rhode Island, United States*

Skilled nursing facilities (SNFs) are on the front lines of changing policies regarding the COVID-19 pandemic. The most recent development is a potential vaccine mandate for staff working in SNFs. We use ongoing findings from 130 of 160 in-depth, semi-structured interviews in progress with administrators at 40 SNFs in eight diverse healthcare markets across the United States to understand the current landscape of COVID-19 in SNFs. Four repeated interviews at 3-month intervals provide a unique longitudinal perspective on the impact of COVID-19 and SNFs' response to vaccinations, including the vaccine mandate. Rigorous thematic analysis reveals insights into administrator responses and creative approaches to address vaccine hesitancy, and future expectations for SNF operations in light of the vaccine and the mandate. Administrators express cautious hope that the vaccine will allow SNFs to return to a new normal of daily life for residents in terms of family visitations, communal dining, and resident activities. Overriding questions include how to overcome persistent vaccine hesitancy from SNF staff who cite fear of side effects despite education initiatives and how to stem staff retirement or transition to other healthcare settings. SNFs represent a microcosm of the country's concerns as a whole. Insight into the evolving and complex dynamics shed important light on national trends and help provide solutions for moving forward. Findings from this study have implications for policymakers and SNF leadership as they consider ways to promote vaccination and retain staff amid vaccine mandates.

CROSS-VALIDATION OF THE FINANCIAL EXPLOITATION VULNERABILITY SCALE

Juno Moray, and Peter Lichtenberg, *Wayne State University, Detroit, Michigan, United States*

Most of the available clinical tools that detect the experience of financial exploitation (FE) are not practical for use by the many professionals who work with older adults. The available measures are often time-consuming, require specialized training to administer, or focus exclusively on the cognitive aspects of financial decision-making. The need for a brief, standardized measure of contextual risk prompted the development of the Financial Exploitation Vulnerability Scale (FEVS; Lichtenberg et al., 2020). The purpose of this study was to cross-validate the FEVS as a psychometrically sound measure of contextual risk for FE. Participants were recruited from the community (n=95), and through a financial coaching service for older adults who had experienced a financial scam (n=21). A total of 114 older adults were recruited for the study, 33 who had experienced FE and 81 who had not. An independent samples t-test demonstrated that the FEVS total score successfully differentiated older adults based on the experience of financial exploitation. The FEVS total score was correlated with age, but no other demographic factors or collected neurocognitive measures. A ROC curve detecting FE analysis revealed an area under the curve of 0.68. Internal consistency of the FEVS was $\alpha=0.80$. In a logistic regression model, only the FEVS and word-reading ability were related to FE. The results of this cross-validation study are very similar to the initial study, demonstrating that

the FEVS is an accessible, theory-based tool that detects the experience of FE.

DECLINING TREND IN USE OF SLEEP MEDICATIONS AMONG OLDER ADULTS IN THE UNITED STATES

Christopher Kaufmann,¹ Adam Spira,² Emerson Wickwire,³ Ramin Mojtabai,² Sonia Ancoli-Israel,⁴ Constance Fung,⁵ and Atul Malhotra,⁴ 1. *University of Florida*, 2. *Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*, 3. *University of Maryland School of Medicine, Baltimore, Maryland, United States*, 4. *University of California San Diego School of Medicine, La Jolla, California, United States*, 5. *VA Greater Los Angeles Healthcare System, North Hills, California, United States*

Recent initiatives to discourage over-prescription of sleep medications have increased awareness of their potential adverse effects in older adults; however, it is unknown whether these efforts translated into a decline in use of these medications in the United States. We assessed recent national trends in the use of medications for sleep disorders. Data came from the 2013-2018 National Health and Nutrition Examination Survey. At each of three waves of in-person assessments, participants presented prescription bottles for all medications used in the prior month. Interviewers recorded each medication and participants self-reported duration and indications for use. We identified all medications used for a sleep disorder and categorized medications into two groups: FDA-approved sleep medications, and medications used off-label (i.e., any other medication reported to be used for sleep disorders). We examined changes in the prevalence in use of these medications across the study period. The odds of using medications for sleep disorders decreased 31% between 2013 and 2018 (odds ratio [OR]=0.69, 95% confidence interval [CI]=0.51-0.92). This trend was driven by declines in use of FDA-approved sleep medications (OR=0.45, 95% CI=0.34, 0.59). Of note, among those age 80+ years, we observed an 86% decline (OR=0.14, 95% CI=0.05-0.36) in the odds of using FDA-approved sleep medications over the study period. Results suggest a possible effect of efforts to curb over-prescription and encourage judicious use of these agents. Future research needs to examine whether these changes have coincided with improved sleep health in the growing population of older adults.

DELIRIUM DURATION PREDICTS 1-MONTH AND 6-MONTH MORTALITY IN SEPTIC PATIENTS FROM AN ACUTE GERIATRICS UNIT

Paolo Mazzola,¹ Antonella Zambon,² and Giuseppe Bellelli,³ 1. *Università degli Studi di Milano-Bicocca, Monza, Lombardia, Italy*, 2. *University of Milano-Bicocca, Milano, Lombardia, Italy*, 3. *University of Milano-Bicocca, Monza, Lombardia, Italy*

Sepsis is highly prevalent in the older population compared to younger age groups. We showed that the SOFA score predicts the risk of death at 30 days in patients discharged from an acute geriatrics unit (AGU). We aim at comparing the ability of both delirium duration and SOFA to predict 1-month and 6-month mortality among septic patients. We performed an observational cohort study recruiting all

patients consecutively admitted to San Gerardo hospital AGU (Italy) between March 2017 and January 2020, aged ≥ 70 , who were diagnosed with sepsis according to 2016 Sepsis-3 criteria. All patients underwent a comprehensive geriatric assessment, including delirium twice a day with the 4AT. Outcomes were 1- and 6-month mortality rates. From 3,326 hospitalized patients, 235 were included in the study (median age 84 years, 42% females). Delirium accounted for 71.9% (169 patients, median duration 3 days). One-month and 6-month mortality rates were 32.3% and 55.3%, respectively. Age, albumin, hemoglobin, and PCR levels were associated with mortality and included as covariates in our Base Model. We performed pairwise comparison between c-indexes of the Base Model vs. Base+delirium duration (days) vs. Base+SOFA. The increment of predictive performance of model including delirium duration was statistically significant (c-index: 0.67 vs. 0.75 when considering 1-month mortality; 0.70 vs. 0.75 for 6-month mortality). Base+delirium duration performed better than Base+SOFA, but the difference not significant. Delirium duration performs as well as SOFA score in predicting 1- and 6-month mortality, with practical implications for the management of these patients in the continuum of care.

DESCRIPTIVE EVIDENCE OF COVID-19'S IMPACT ON BLACK LGBTQ ADULTS AMIDST ONGOING HEALTH INEQUITIES

Charleigh Flohr,¹ and Cassandra Burton,² 1. *Human Rights Campaign Foundation, Washington, District of Columbia, United States*, 2. *AARP, Atlanta, Georgia, United States*

Black LGBTQ people significant challenges and discrimination as they face the barriers of living at the intersection of multiply marginalized identities, which have worsened during the coronavirus pandemic. At a baseline, LGBTQ people exhibit elevated risk of being negatively impacted by the pandemic across health, economic and other social outcomes (Cahill et al., 2020; Heslin & Hall, 2021; Human Rights Campaign, 2020). Black LGBTQ people have also suffered significant economic losses (Human Rights Campaign Foundation, 2020). Methods: The Human Rights Campaign Foundation and AARP supported and partnered with Community Marketing & Insights to conduct a survey of 1,815 Black LGBTQ adults in the United States. The online survey was fielded between September 21 and October 30, 2020. Many Black LGBTQ adult participants report healthcare discrimination in the last three years, with 19% reporting racial discrimination and 11% reporting sexual orientation-based discrimination. Furthermore, 31% of Black transgender adults report healthcare discrimination in the last three years. Preventing or treating COVID-19 is an important health concern to 67% of Black LGBTQ adults aged fifty-five and older, 63% of Black LGBTQ adults aged thirty-five to fifty-four and 53% aged eighteen to thirty-four. Overall, Black LGBTQ adults report being significantly impacted by the pandemic, including negative impacts on their social health (60%), mental health (44%), the physical health of their close friends and family (33%), their finances (30%), and their employment status (22%). Overall, one-quarter (25%) of Black LGBTQ adults had at least one close friend or family member die from coronavirus illness.

DISABILITY & SLEEP QUALITY OF CUSTODIAL GRANDPARENTS DURING FALL 2020 OF THE COVID-19 PANDEMIC

Kellie Mayfield,¹ Karen Clark,² and Raeda Anderson,³
 1. Georgia State University Byrdine Lewis College of Nursing and Health, Atlanta, Georgia, United States, 2. Southern University and A&M College, Baton Rouge, Louisiana, United States, 3. Shepherd Center, Atlanta, Georgia, United States

Disability of custodial grandparents, grandparents who are the primary caretakers of their grandchildren often in parent absent households, are not frequently examined. One in four adults in the U.S. lives with a disability with the highest percentage of disabilities reported in the South. Quality sleep is integral for overall wellbeing and is altered with age. Sleep complaints of older adults are associated with multiple adverse health outcomes such as dementia, stroke and obesity. The objective of this study was to examine the relationship between disability and sleep quality amongst custodial grandparents during the COVID-19, Fall 2019 in Georgia. Thirty-four custodial grandparents were recruited from the Georgia Division of Aging Kinship Care Support Groups, ages 42 to 78, with most identifying as African American. Disability status and the Pittsburgh Sleep Quality Index were measured. Results showed a significant negative relationship for custodial grandparents' disability status and sleep quality ($\chi^2= 9.167$, $p=0.027$; $\Gamma=-0.683$, $p=0.002$), sleep disturbance ($\chi^2= 12.150$, $p=0.002$; $\Gamma=-0.897$, $p<.001$), and use of sleeping medication ($\chi^2= 9.645$, $p=0.022$; $\Gamma=-0.785$, $p<.001$). Custodial grandparents with a disability had worse sleep quality, more sleep disturbances, and took more sleeping medication compared to custodial grandparents without a disability. Results have implications for kinship care providers and medical practitioners when engaging with custodial grandparents about their health, disability and impacts on their sleep quality.

DO CAREGIVER INTERVENTIONS IMPROVE OUTCOMES IN RELATIVES WITH DEMENTIA? A META-ANALYSIS

Sheung-Tak Cheng, *The Education University of Hong Kong, The Education University of Hong Kong, Hong Kong*
 Despite plenty of reviews on the benefits of nonpharmacological interventions for dementia informal caregivers, large-scale review on the effects of these interventions on the care-recipients (CRs) is lacking. We searched PsycINFO, CINAHL with Full Text, MEDLINE, and PubMed from inception to end of 2020 and found 144 articles that reported randomized controlled trials of caregiver interventions using CR outcomes. Interventions were found to reduce neuropsychiatric symptoms and mood disturbance, enhance cognition and quality of life, and delay institutionalization and mortality, with care coordination/case management, educational intervention with psychotherapeutic components, and direct training of the care-recipient (with caregiver involvement) being the more potent interventions. However, the effects were generally small to very small. Together with existing findings on caregiver outcomes, a tripartite scaffolding model of caregiver support is proposed. Future directions in terms of developing consensual guidelines, a registry

of intervention manuals, and family-centered programs are discussed.

DOES RETIREMENT AGE IMPACT FUNCTIONAL LIMITATIONS IN LATER LIFE?

Ziyao Xu, *Miami University, Oxford, Ohio, United States*

The US government is gradually shifting the full retirement age in Social Security to age 67. However, previous studies suggest that this shift could negatively impact the mental and physical health of retirees. To understand the potential impact of raising the full retirement age on the functional health of retirees, this longitudinal study examined changes in physical functioning over time in retirees by age at retirement. Twelve waves of the Health and Retirement Study (1994 – 2018) were used. A total of 8,261 retirees was included. The retirement age was a categorical variable: very early age (<62), early age (62-64), traditional age (65-67), and late age (>67). Physical functioning was measured using 15 Activities of Daily Living and Instrumental Activities of Daily Living. A GEE model was used to assess the relationship between the retirement age category and the number of functional limitations. In the adjusted model, after controlling for all the other variables including baseline health and functioning, late retirement was associated with an 8.9% increased risk of functional limitations compared to traditional age retirement (IRR: 0.91, 95% CI:0.84 – 0.98). Compared to late retirees, the risk of functional limitations was increased by 28.6% in very early age retirees (IRR: 1.29, 95% CI:1.21–1.36). Compared to those retiring at traditional retirement age, those retiring late, after 67, have increased the risks of functional limitations. Although levels of disability could influence age of retirement, these results suggest that for some workers efforts to increase age of full retirement, could have negative effects.

DYADIC PERCEPTIONS OF COVID-19 PANDEMIC IMPACT ON EVERYDAY LIFE

Jennifer Margrett,¹ Celinda Reese-Melancon,² Dan Russell,¹ Lauren Stratton,¹ Erin Harrington,³ and Jyoti Savla,⁴
 1. Iowa State University, Ames, Iowa, United States, 2. Oklahoma State University, Oklahoma State University, Oklahoma, United States, 3. Pennsylvania State University, University Park, Pennsylvania, United States, 4. Virginia Tech, Blacksburg, Virginia, United States

It is important to understand the effects of the COVID-19 pandemic not only on individuals' daily lives, but also their close partners. Current literature suggests that the COVID-19 pandemic has impacted older adults' lives in several ways, including the frequency of social interactions and change in various life habits (Lesbrasseur et al., 2021). Data from 42 middle-aged and older, long-term married or cohabitating dyads were collected as part of an ongoing study of everyday cognition and functioning among couples. Participant age ranged from 40-85+, and couples were partnered for 9-60+ years. During this study, COVID-19 pandemic impact was assessed using six items (1 = No change to 4 = Severe change) examining daily routines, medical and mental health access, social contacts, and pandemic and family-related stress; reports ranged from six to 19. On average, women reported significantly higher COVID-19 pandemic impact compared

to men. For both partners, the greatest disruptions reported related to routines and social contacts. Further analysis examined COVID-19 pandemic impact in dyads. For eight dyads, both partners reported relatively lower COVID-19 impact (6-11), whereas for six dyads, both partners reported higher impact scores (14-19). Discussion focuses on within-dyad and between-dyad differences related to perceptions of the pandemic's impact.

EFFECTS OF A MULTIPLE CHRONIC CONDITION (CC) REMOTE MONITORING PROGRAM ON CLINICAL OUTCOMES AMONG OLDER ADULTS

Eldin Dzubur,¹ Jessica Yu,² Roberta James,² Julia Hoffman,² and Bimal Shah,² 1. *Teladoc Health, Pasadena, California, United States*, 2. *Teladoc Health, Mountain View, California, United States*

Older adults are faced with an increased risk of comorbid chronic disease such as diabetes. While multiple health behavior change interventions (MHCI) are known to improve clinical outcomes more than targeted interventions, less is known whether such effects persist in older populations. The objective of the study was to examine the effects of multiple chronic condition (CC) remote monitoring program enrollment and mental health program enrollment on glucose and blood pressure reduction, adjusting for self-monitoring behaviors. In a sample of 594 older adults (age 55+, 14% 65+ years, 46.8% female) evaluated over a 12-month period, statistical models showed that older adults with uncontrolled diabetes (A1c \geq 7.0%) had a 7.9 pt. reduction in blood glucose for each additional program enrolled and a 22.7 pt. reduction in blood glucose when enrolled in mental health compared to those not enrolled. Similarly, older adults with uncontrolled hypertension (BP \geq 130/80) had a 4.8 pt. reduction in systolic blood pressure for each additional program enrolled and a 7.2 pt. reduction in systolic blood pressure when enrolled in mental health compared to those not enrolled. The findings indicate the potential for multiprogram digital health interventions that incorporate mental health to further improve clinical outcomes in older adults suffering from multiple chronic diseases, namely diabetes and hypertension.

EFFECTS OF OBESITY REDUCTION ON PHYSICAL FUNCTION, INFLAMMATION AND OSTEOARTHRITIS IN OLDER ADULTS

Michael Borack,¹ Abigail Holt,² Kathryn Porter Starr,³ Jamie Rincker,² James Coppock,² Connie Bales,¹ Lou DeFrate,² and Amy McNulty,² 1. *Duke University School of Medicine, Durham, North Carolina, United States*, 2. *Duke University, Durham, North Carolina, United States*, 3. *Duke University School of Medicine, Hillsborough, North Carolina, United States*

Age-related increases in chronic inflammation lead to reduced physical function via damage to muscle and joints and contribute to osteoarthritis (OA) risk. Obesity in older adults with OA further exacerbates inflammatory damage. Whether obesity reduction can lessen inflammation and improve OA is unknown; however, novel biomarkers may provide an answer. We completed a 6-mo. weight loss intervention (-500 kcal/day), studying blood biomarkers of inflammation and

cartilage damage along with physical function in obese older adults with (OA+; n=39) and without an OA diagnosis (OA-; n=20). Participants were aged > 60 yrs (mean = 70.2 \pm 6.0) and obese (BMI =34.6 \pm 4.7 kg/m²). At endpoint, weight loss was -6.3 \pm 4.0% and -5.8 \pm 4.1% in OA+ and OA-, respectively, with no group difference. Change scores for function for OA+ and OA- were: Short Physical Performance Battery score (+1.7 \pm 1.3 and +2.1 \pm 1.5), 8 ft up and go (-0.7 \pm 1.0 and -0.9 \pm 1.12 sec) and 6 min walk (+31.4 \pm 105.1 and +39.5 \pm 57.4 meters). All improved from baseline (p<0.05), with no group difference. Concerning blood biomarkers, there was a decrease (p<0.05) in cartilage oligomeric matrix protein (COMP: OA biomarker), indicating a potential benefit for OA. Change in COMP also differed between groups; OA- had a greater (p<0.05) reduction than OA+. Pooled results showed improved adiponectin (p<0.05), with no group difference. There were no changes for CRP, CTX-1, IL-6 and TNF- α . Our novel findings link early intervention with better reduction of OA risk and inflammation in obese older adults and also show important benefits for improved physical function regardless of OA status.

EXAMINING DIFFERENT TYPES OF SLEEP AMONG CUSTODIAL GRANDPARENTS DURING COVID-19

Karen Clark,¹ Kellie Mayfield,² and Raeda Anderson,³ 1. *Southern University and A&M College, Baton Rouge, Louisiana, United States*, 2. *Georgia State University Byrdine Lewis College of Nursing and Health, Atlanta, Georgia, United States*, 3. *Shepherd Center, Atlanta, Georgia, United States*

Sleep is associated with healthy living. With increased age, sleep is harder to initiate and maintain. Currently, over two million grandparents have become primary caregivers to their grandchildren and are at risk for poor sleep outcomes. Research shows that grandparent caregivers are at risk for depression due to poor sleep quality. Thus, this study aimed to identify the sleep quality of custodial grandparents to gain a better understanding of sleep patterns during COVID-19 in 2020. Thirty-four custodial grandparents were recruited from the Georgia Division of Aging Kinship Care Support Groups from September through October 2020. Participants were between 42 to 78 years old with a mean age of 57. Participants completed the Pittsburgh Sleep Quality Index. Stata statistical software was used to analyze the relationship between the sleep quality subscales. Results showed a significant positive relationship for custodial grandparents between sleep quality and daytime dysfunction ($\chi^2=25.993$, p=0.002; $\Gamma=0.495$, p=0.039) as well as sleep quality and sleep disturbance ($\chi^2=11.129$, p=0.084; $\Gamma=0.751$, p<0.001). There is a significant positive relationship between daytime dysfunction and sleep duration ($\chi^2=14.984$, p=0.091; $\Gamma=0.681$, p<.001), where grandparents with daytime dysfunction have longer sleep duration. Findings suggest grandparents with poor sleep quality are more likely to experience daytime dysfunction and have more sleep disturbances in the COVID-19 environment. Our study will benefit researchers and practitioners caring for custodial grandparents and contribute to future research focused on custodial grandparents and sleep quality.

EXPLORE THE ROLE OF ABETA IN AXONAL TRAFFICKING DEFICITS INDUCED BY ALPHA SYNUCLEIN IN PARKINSON DISEASE MOUSE MODEL
 Alfredo Castro, *UCSD MADURA R25 Advancing Diversity in Aging Research Program, La Jolla, California, United States*

Alpha synuclein (ASYN) is a neuronal protein that is observed in significant amounts in the brain and is encoded for by the SNCA gene, it functions as a regulator for the trafficking of synaptic vesicles. It has been noted that the buildup of alpha synuclein has been found in the form of Lewy bodies in studies involving patients with Parkinson's diseases (PD). Gaining an understanding for the manner in which alpha synuclein affects the synaptic structure and the movement of axonal trafficking will help further our understanding towards the formation of Lewy bodies. Experimenting with the way in which ASYN affected the intervention of Abeta was important, to see the toxicity of Abeta in axonal trafficking. The PD and SynKO mouse models treated with Abeta both showed an effect on the anterograde moving speed of both the PD and SynKO neurons. Synaptic formation was examined, and it was found that ASYN had a large negative influence on the synapse formation in PD neurons. This was due to the significantly reduced colocalization that was found in the treated neurons. It was confirmed that ASYN caused neuronal atrophy through the over expression of GFP-ASYNWT wild type or the GFP-ASYN A53T. Comprehending ASYN effect on the axonal trafficking and the synaptic structure of PD neurons can help understand the mechanism that may be present which possibly stimulates Alzheimer's Disease in PD patients.

EXPLORING THE ECOLOGY OF THIRD AGE INFORMAL LANGUAGE LEARNER GROUPS
 Gareth Barnes, *Macquarie University, Australia*

This research explores the factors involved in the emergence of an independently organized Third Age informal language learner group in a community centre in Japan. The methodology applies PPCT (Process-Person-Context-Time) from Bronfenbrenner's bioecological approach to provide a detailed perspective of the people, the environment and settings over time to show how these factors interact to construct an emergent learner group. The analysis looks at how and why this specific learner ecology emerges and ultimately, how it can benefit the Third Age and inform healthy ageing policy. The findings show that by engaging in second language learning, the participants find meaningful and active involvement in the group by creating a setting that welcomes self-expression, while balancing limiting and facilitating factors of resilience and reciprocal support, self-management, sage-ing, interest, agency, and responsibility. The result is the creation of a multilingual, multicultural, and multigenerational place of inclusion within the community. The study highlights the heterogeneity of the 3rd Age and illustrates the interplay of contexts outside of the learner group from micro to macro, individual and group resources, and the influence of the specific social time period. It also shows the social importance of creating opportunities for autonomous informal language learning settings in the community while highlighting the impact of Third Age agency.

FALLS AMONG OLDER ADULTS IN THE PHILIPPINES AND VIETNAM: RESULTS FROM NATIONALLY REPRESENTATIVE SAMPLES

Tuo Yu Chen,¹ Grace Cruz,² Cong Nguyen Vu,³ and Yasuhiko Saito,⁴ 1. *Taipei Medical University, Taipei, Taipei, Taiwan (Republic of China)*, 2. *University of Philippines, Quezon City, Quezon, Philippines*, 3. *Institute of Population, Health and Development, Ha Noi, Ha Noi, Vietnam*, 4. *Nihon University, Tokyo, Tokyo, Japan*

Falls are a major public health issues globally. However, no study with nationally representative samples, previously, had been done to understand falls among older adults in the Philippines and Vietnam. Using a biopsychosocial perspective, this study investigated the prevalence of falls and their associated factors among community-dwelling older adults in these countries. Cross-sectional data were drawn from the Longitudinal Study of Ageing and Health in the Philippines (N = 4,606) and the Longitudinal Study of Ageing and Health in Vietnam (N = 4,378). The outcome variables were any falls in the past year. Independent variables included biophysical factors (vision/chronic conditions/functional impairments/pain locations/insomnia symptoms/sleep medications/grip strength/walking speed/postural control), psychological factors (depressive symptoms), and sociodemographic factors (age/sex/education/living in urban area/living alone/social network size). Descriptive analysis and logistic regression analysis were used to analyze data. The results showed that 17.7% of the Filipino older adults fell in the past year and it was 7.3% among Vietnamese older adults. Significant factors that increased the odds of any falls among Filipino older adults were having a higher level of education, living in urban area, living with others, experiencing more functional impairments, reporting one or more pain locations, and having poor grip strength. In Vietnam, having more chronic conditions, experiencing more functional impairments, and reporting two or more pain locations were found to increase the odds of any falls. Population in the Philippines and Vietnam are aging rapidly. Findings from this study are timely in identifying at-risk individuals and preparing for effective falls prevention strategies.

FEAR OF FALLING, FALL RISK, DEPRESSION, AND ANXIETY IN COMMUNITY-DWELLING OLDER ADULTS

Aleatha Rossler,¹ Ladda Thiamwong,² Rui Xie,¹ Jeffrey Stout,¹ Joon-Hyuk Park,¹ Renoa Choudhury,¹ and Oscar Garcia,¹ 1. *University of Central Florida, Orlando, Florida, United States*, 2. *College of Nursing, University of Central Florida, Orlando, Florida, United States*

Fear of falling is common in the older adult population with an estimated 43% being affected. We aimed to examine the associations among fear of falling, fall risk, depression, and anxiety in community-dwelling older adults. For this study 124 participants ranging from 60 to 96 years of age were recruited from the community settings in Central Florida. Fear of falling, fall risk, depression and anxiety were assessed using the Falls Efficacy Scale International (FES-I), the CDCSTEADI fall risk assessment, the Patient Health Questionnaire (PHQ) for depression, and the Geriatric Anxiety Inventory Short form (GAI-SF) for anxiety respectively. Data was collected via the Qualtrics survey.

Comparisons were made for those below age 75 and those aged 75 and older, with 51.6% being under 75. Four ethnicity categories were also used: African American (8.1%), Asian (2.4%), Hispanic (14.5%), and non-Hispanic white (75%). All participants scored above 4 on the STEADI scale indicating fall risk. 42 scored positive for fear of falling on the FES-I scale and of that 42, 35.7% had a history of one or more falls in the last year ($p < .01$). 46.8% of the participants screened positive for depression and 100% of participants were positive for anxiety. Using one-way ANOVA analysis, we found significant relationships between (1) depression ($p < .01$); (2) STEADI ($p < .01$) and FES-I.

FEASIBILITY OF COMBINING NONINVASIVE BRAIN STIMULATION AND PERSONALIZED COUNSELING TO INCREASE PHYSICAL ACTIVITY

On-Yee (Amy) Lo,¹ Connor Mulvey,² Christine Lee,²

Margaret Gagnon,² Lewis Lipsitz,² and Brad Manor,³

1. *Hebrew SeniorLife/Harvard Medical School, Boston, Massachusetts, United States*, 2. *Hebrew SeniorLife, Boston, Massachusetts, United States*, 3. *Hinda and Arthur Marcus Institute for Aging Research, Harvard Medical School, Boston, Massachusetts, United States*

Few older adults meet recommended physical activity guidelines. Behavioral interventions may be more effective when combined with other modalities to promote activity. Transcranial direct current stimulation (tDCS) designed to increase the excitability of the left dorsolateral prefrontal cortex (dlPFC) — a brain region subserving motivation and executive function — has the potential to augment behavioral interventions. We designed a randomized, double-blinded trial to examine the feasibility of combining personalized behavioral counseling and tDCS targeting the left dlPFC to improve physical activity and related outcomes in sedentary older adults living within the supportive housing. Participants wore a Fit-Bit throughout the study period. Baseline step counts were determined for two weeks, then participants completed four bi-weekly personalized counseling sessions over eight weeks. They were also randomized to receive 10 sessions of tDCS or sham stimulation over the two weeks after the baseline. Physical, cognitive, and patient-reported outcomes were assessed at baseline, after ten brain stimulation sessions, and after four behavioral sessions. 33 individuals were screened and 16 enrolled (age=80±7, 13 females). 13 participants completed the study, including 100% of study assessments, 99±5% of brain stimulation sessions, and 98±7% of behavioral sessions. Fit-Bit adherence rate was 93±13%. Daily step counts were 3197±1480 at baseline and 4722±2553 over the last two weeks of the intervention. While the study is ongoing and blinded, these preliminary results indicate that it is feasible to conduct a controlled study of tDCS combined with personalized behavioral counseling to increase physical activity in sedentary older adults living within supportive housing.

FEASIBILITY OF USING A COMMERCIAL BOARD GAME TO ASSESS UPPER EXTREMITY FUNCTION IN OLDER ADULTS

Allison Niemic,¹ Yareli Lopez Hernandez,²

Ejlal Bin Mulayh,² Rachel Logue,¹ and Susan Brown,¹

1. *University of Michigan, Ann Arbor, Michigan, United*

States, 2. *University of Michigan, University of Michigan, Michigan, United States*

Upper extremity function, particularly the hand, declines with aging and is predictive of executive ability and independence. Standard assessments typically focus on strength partly due to a lack of easily administered functional tasks requiring multi-joint coordination and precision grasp. This study aimed to determine the feasibility of using an inexpensive board game to assess upper extremity function in older adults. Six healthy older adults (77 +/- 5.1 years) completed reaching tasks using the Connect4® game that requires grasping and placing small discs into a vertical board. Tasks included different hand configurations (unilateral, bilateral), and two dual-task conditions (serial subtraction by 7s and placing colored discs to match specific color patterns). The time to complete each task was recorded. For comparison purposes, participants completed a standardized pegboard test (Purdue Pegboard) using one or both hands. Connect4 results were similar to age-normative findings reported for the Purdue Pegboard. Dominant versus non-dominant hand performance did not differ while bilateral coordination tasks were slower than unilateral tasks for both the Purdue Pegboard ($p < 0.05$) and Connect4 ($p < 0.01$). Pegboard and Connect4 times were moderately to strongly correlated for all hand configurations. Dual-task conditions using Connect4 led to longer completion times ($p < 0.05$). Preliminary results support the use of Connect4 as a functional upper extremity assessment tool for older adults. It is inexpensive, engaging, easy to use, and allows for cognitive-motor assessment using dual-task protocols, a critical factor in maintaining functional independence in older individuals. Further research will include a formal validation study across a wider age range.

FOOT MECHANICS DEFINE DIRECTIONAL CHANGES IN CURVED-PATH WALKING: NEW METHODS TO ASSESS THE MOTOR SKILL OF WALKING

Haley Hicks,¹ Anthony McBroom,² Patrick Roscher,³

Jessie VanSwearingen,⁴ and Kristin Lowry,⁵

1. *Broadlawns Medical Center, Des Moines, Iowa, United States*, 2. *Des Moines University, Des Moines, Iowa, United States*, 3. *Protokinetics, Inc, Havortown, Pennsylvania, United States*, 4. *School of Health and Rehabilitation Sciences, Pittsburgh, Pennsylvania, United States*, 5. *University of Pittsburgh, University of Pittsburgh, Pennsylvania, United States*

Although it is essential to navigating the world, curved path walking is a challenge to mediolateral balance control. The focus of previous curved-path walking research was in spatiotemporal characteristics. We quantified the foot-ground interaction, center of pressure (COP) characteristics during non-linear (eg curved-path) walking important to understand the functional mechanics of directional changes for curved paths. We hypothesized the foot mechanics differ between older adults with better versus poorer curved-path walking (Figure of 8 Walk Test, F8W). Twenty-five older adults (mean age 71.8 ± 8.9 years) completed the F8W on an instrumented walkway (Protokinetics, LLC.) The derived metrics of the foot mechanics included medial/lateral movement of the COP for inside and outside steps, maximum medial and lateral COP excursions, and total medial/lateral COP range. Pearson correlations were used to examine

relations F8W (time and steps) and COP metrics; ANOVAs were used to examine differences in COP metrics between older adults grouped by median-split of F8W time. Longer F8W time and more steps were related to lesser total COP range and outside foot lateral maximum excursion (r range -0.415 to -0.706, $p < 0.04$). Older adults with stronger F8W performance compared to poorer F8W performance had larger outside foot total COP ranges (3.61cm vs 4.39cm, $p = 0.016$) and greater lateral excursion (1.60cm vs 2.12cm, $p = 0.003$). Foot-ground interactions offer new insights into control of curved path walking and methods for evaluating efficacy of interventions focused on improving walking skill in older adults.

HETEROGENEOUS PATTERNS OF OLD-AGE VULNERABILITY AND LONELINESS FROM THE CROSS-NATIONAL COMPARATIVE PERSPECTIVE

Oejin Shin,¹ sojung park,² Ji young Kang,³ Minyoung Kwak,⁴ and Jihye Baek,⁵ 1. *University of Illinois at Urbana Champaign, Savoy, Illinois, United States*, 2. *Washington university, St. Louis, Missouri, United States*, 3. *Chungnam National University, Daejeon, Ch'ungch'ongnamdo, Republic of Korea*, 4. *Daegu University, Gyeongsan, Gyeongbuk, Kyongsang-bukto, Republic of Korea*, 5. *Gwanak Senior Welfare Center, St. Louis, Missouri, United States*

Loneliness has been extensively examined as a major risk factor for mortality and morbidity among older adults. In this research, we identified multi-dimensional patterns of old-age vulnerability in five countries (U.S., Korea, Sweden, Germany, Italy) guided by the welfare regime framework and examined how the patterns of vulnerability are associated with loneliness in old age in each country. Data were drawn from comparative national aging data: HRS for the U.S. ($n = 4331$), KLOSA for Korea ($n = 3721$), SHARE for Sweden ($n = 2746$), Germany ($n = 2271$), and Italy ($n = 2988$). We used three vulnerability constructs: 1) material vulnerability (poverty, high out-of-pocket expenses for health care, unaffordability for housing), 2) health vulnerability (multiple chronic condition, depression), and 3) social vulnerability (living alone, contact with children and friend, social participation). Latent Class Analysis and regression analyses were used for data analysis. The relative proportion of the least vulnerable group varies substantially (from 11.88% in Italy to 59.33% in the U.S). In Sweden and Germany, around 7% of the sample belongs to the most vulnerable group, while in other countries the most vulnerable group was not found. Notably, in Italy, older people in the social vulnerable group were more likely to feel lonely when compared to least vulnerable, suggesting the country-specific significance of social supportive environment. This study is the first research to examine the empirical structure of the concept and how it may vary across countries related to their loneliness. A full discussion of country-specific discussion and policy implication will be presented.

HIPPOCAMPAL KNOCKOUT OF P300 AFFECTS LEARNING AND MEMORY IN MICE

Chase Rector,¹ and Lin Wang,² 1. *Howard University, Brandywine, Maryland, United States*, 2. *NIH, NIH, Maryland, United States*

Aging has been associated with cognitive decline, as seen in various learning and memory processes. Specifically, p300, a lysine acetyltransferase, has been shown to decrease with age, which could have an effect on cognition. In a series of behavioral tests, the effect of the knockout of p300 was studied in mice. In the water T maze test and the object recognition test, the results conveyed that the mice's learning skills had not been impacted by the knockout of p300. But the water T maze test results further showed that the p300 knockout mice had a decline in their cognitive flexibility to new information. These findings suggest that the knockout of p300 has a negative impact on cognition. We expect that the overexpression of p300 in older mice will restore the cognition that might have been lost with aging.

HOME CARE PHYSICAL THERAPISTS' VIEWS ON INTER-PROFESSIONAL SHARED DECISION MAKING

Cindy Moore, *Rutgers University, Hamilton, New Jersey, United States*

Shared decision making (SDM) has been associated with increased patient satisfaction and engagement and improved process and care outcomes. However, SDM use by physical therapists (PTs) working with older adults in the home care setting is not known. Understanding home care PTs' views about and experiences with SDM, including inter-professional SDM, can inform SDM research and strategies for increasing its use. This presentation highlights inter-professional aspects of SDM described by home care PTs in the qualitative arm of a mixed methods, implementation science framework-informed study exploring PTs' perspectives on SDM in home care. Semi-structured interview data from twenty PTs (80% female; mean age = 50.6, SD=12.7, range 28-73) representing all geographic regions of the continental United States and having varied levels of geriatric (mean 24.2 years, SD=11.6, range 3-40) and home care (mean 15.7, SD=11.5, range 2-40) experience were analyzed using thematic content analysis. A trustworthiness plan guided data collection and analysis, and reflexive journaling, memo, audit trail, peer debriefing, data triangulation, and member checking were used to support study rigor. Three inter-professional SDM-related themes were identified: team members facilitating SDM for all disciplines; within-team sharing of and competition for patient care resources; and limited patient/caregiver participation in team treatment planning decisions. Findings support the need for including inter-professional issues in home care SDM implementation and measurement research and suggest topics to include in future studies.

HOSPICE CAREGIVER BURDEN AND WORK PRODUCTIVITY: AN EXPLORATORY ANALYSIS

Megan Thomas Hebdon,¹ Jiayun Xu,² Djin Tay,³ Maija Reblin,⁴ Kristin Cloyes,⁵ and Lee Ellington,³ 1. *University of Texas at Austin, University of Texas at Austin, Texas, United States*, 2. *Purdue University, Purdue University, Indiana, United States*, 3. *University of Utah, Salt Lake City, Utah, United States*, 4. *University of Vermont, Burlington, Vermont, United States*, 5. *University of Utah, Portland, Oregon, United States*

Hospice caregivers experience burden that impacts their physical, emotional, and social well-being. Little is known about how caregiver burden impacts occupational well-being

through employment and work productivity. Thus, our purpose was to explore the relationships between caregiver burden and dimensions of work productivity/impairment (absenteeism, presenteeism, activity impairment, and overall impairment) among working hospice cancer caregivers. This is a secondary data analysis of baseline data from a larger study of caregiver communication and bereavement. Study data including demographics, preparedness for caregiving, caregiver burden, and work productivity/impairment were analyzed using descriptive statistics, correlation analysis, and stepwise multiple linear regression. Dimensions of work productivity/impairment were dependent variables, and age and preparedness for caregiving were covariates. Working caregivers (N=54) had an average age of 52 (SD: 12.65), and were primarily White (83%), female (70%), married (69%), employed full-time (70%) and had a household income of \$50,000 or more (65%). Greater caregiver burden was significantly associated with lower preparedness for caregiving ($r=-.41$, $p<.01$), and greater activity impairment ($r=.50$, $p<.01$), presenteeism ($r=.44$, $p<.01$), and overall impairment ($r=.36$, $p<.05$), but not absenteeism. Caregiver burden predicted activity impairment ($b=1.72$ [.72, 2.71], $p<.01$), presenteeism ($b=1.44$ [.33, 2.55], $p<.01$), and overall impairment ($b=1.42$ [.09, 2.74], $p<.05$), even after controlling for age and preparation for caregiving. More burdened caregivers may be having more challenges with work productivity. Additional research is needed to examine these relationships in a larger, more diverse sample. Future research should also investigate how supportive work environments and leave policies reduce caregiver burden and promote work productivity.

IMPACT OF RECREATIONAL PHYSICAL ACTIVITY AND BODY COMPOSITION ON INSULIN RESISTANCE IN OLDER ADULT POPULATION

Pao-Feng Tsai, Chih-Hsuan Wang, Caralise Hunt, Sarah Watts, and Katilya Ware, *Auburn University, Auburn, Alabama, United States*

Purpose: The study was to identify the impact of physical activity (PA) and body composition on insulin resistance in older adults and investigate racial/ethnic difference in these relationships. **Method:** This secondary data analysis project used 717 participants who were 55 years and older without diabetes from the 2017-2018 National Health and Nutrition Examination Survey. Major variables included homeostatic model assessment of insulin resistance (HOMA-IR), body mass index (BMI), waist circumference (WC), and recreational PA. The covariates included were demographics, nutrition intake, and lifestyle (smoking and alcohol usage). Hierarchical multiple regressions were conducted to analyze the data. **Results:** Body composition and recreational PA had interaction and main effects on HOMA-IR in the overall sample. Level of HOMA-IR decreased with increasing levels of recreational PA in individuals with lower levels of BMI, but in individuals with higher levels of BMI, HOMA-IR increased. Level of HOMA-IR increased with increasing levels of recreational PA across the range of WCs, but the rate of increase was slightly more pronounced at higher level of WCs. These results varied across racial/ethnic groups. **Conclusion:** Overall, both recreational PA and body composition are important factors that affect level of HOMA-IR, but body composition seems to be the dominant factor. PA is only

beneficial for older adults with low BMI. Interventions for reducing insulin resistance should be tailored to specific racial/ethnic groups.

IT TAKES A VILLAGE - ATYPICAL PRESENTATION WARRANTS TEAMWORK FOR SEPSIS CARE

Teresa Cranston, and Nicole Bailey, *Penn Medicine Lancaster General Health, Lancaster, Pennsylvania, United States*

Sepsis is the body's overwhelming response to infection that can lead to tissue damage, organ failure, and death. Sepsis, disproportionately, affects older adults due to an aging immune system and chronic illness. Older adults present atypically delaying diagnosis and intervention. This delay has been associated with increased morbidity and mortality. However, with early detection and rapid treatment there can be a reduction in poor outcomes. It is key, that clinicians practice collaboration and communication when diagnosing & treating patients that may have a different presentation. Early detection, monitoring, and intervention are crucial to survival of the older septic patient. The Continuous Monitoring Unit (CMU) consists of RNs, who monitor telemetry, video, and the Sepsis BPA/Checklist 24 hours/7 days a week. These nurses evaluate all active ED and acute care BPA data points. With their specific training, they dismiss the irrelevant and align the significant data while looking for possible notes of infection. They do not act upon the BPA unless the patient meets criteria. If there is confirmation of the BPA, the nurse collaborates with the primary provider to initiate recommended sepsis care. Since the beginning of August 2021, the CMU RN is utilizing the Sepsis Checklist, a customized tool built into the EMR that allows the CMU nurse to monitor the key elements of the Sepsis Bundle and intervene concurrently to complete the CMS SEP1 recommendations. Recommendations are based on the Surviving Sepsis Campaign.

LATENT CLASSES OF FIRST INCIDENT DIFFICULTY IN INSTRUMENTAL ACTIVITIES OF DAILY LIVING

Danielle Feger,¹ Jennifer Deal,¹ and Alden Gross,² *1. Johns Hopkins University, Baltimore, Maryland, United States, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*

Ability to perform instrumental activities of daily living (IADLs) deteriorates during prodromal Alzheimer's disease (AD), eventually leading to impaired everyday functioning and dementia. Ordering and timing of IADL difficulty onset may identify individuals at greater risk of cognitive impairment, but most studies only consider total number of difficult tasks. Leveraging longitudinal data from the Advanced Cognitive Training in Independent and Vital Elderly (ACTIVE) Study who entered free of any IADL difficulty (N=1266), we hypothesized that a latent class analysis based on timing of first reported IADL task difficulty would reveal class differences in cognitive functioning. Participants were followed until they self-reported at least one IADL difficulty, study completion (10 years), or loss to follow-up. Discrete-time multiple event process survival mixture (MEPSUM) models were used to simultaneously estimate hazards of incident IADL task difficulty across 7 task groups. Two, 3, 4, and 5 latent class models were fit to the data. Both unadjusted

and covariate-adjusted models (adjusted for age, sex, race, education, marital status, and general health rating) were fit. Using the 2-class solution as the most parsimonious model, model entropy was 0.855. The model was able to distinguish a class of participants with lower global cognitive factor scores at baseline (Cohen's $D = 0.23$, $P = 0.04$). We conclude that first incident IADL difficulty may be a useful measure in identifying individuals with worse cognitive functioning.

LIFESPAN DEVELOPMENTAL ANALYSIS OF HEALTH PROBLEMS AND PROBLEM DRINKING ACROSS WHITE AND UNDERREPRESENTED ADULTS

Willard Boyd,¹ Yimei Li,² Mohammed Ahmed,³ Dania Mohammed,⁴ Thomas Kwan,⁵ and Matthew Lee,⁶
 1. Rutgers The State University of NJ, Weehawken, New Jersey, United States, 2. Rutgers The State University of NJ, Piscataway, New Jersey, United States, 3. Rutgers The State University of New Jersey, Rutgers Center of Alcohol & Substance Use Studies, New Jersey, United States, 4. Rutgers Center of Alcohol & Substance Use Studies, Rutgers Center of Alcohol & Substance Use Studies, New Jersey, United States, 5. Rutgers University, Manalapan, New Jersey, United States, 6. Rutgers University, Piscataway, New Jersey, United States

Research has illustrated potential health benefits from moderate drinking, but also health risks from excessive drinking. Few studies have contrasted drinking effects on health across different periods of the lifespan, and how such contrasts may vary across sociodemographic subpopulations. In this study, we investigated underrepresented racial and ethnic group status as a moderator of drinking effects on health across the lifespan. Analyses used data from two waves of a large U.S.-representative sample. We estimated a series of 3*3 between-persons ANOVAs testing effects of Wave-1 drinking group (abstainer, moderate drinkers, and excessive drinkers), age (young adulthood, midlife, and older adulthood), and drinking-group-by-age interactions in White versus underrepresented status. The outcome variable was Wave-2 hypertension (controlling for Wave-1 hypertension). In the older-adult White group, results reflected the familiar “j-shaped” curve of alcohol effects on health. Specifically, abstainers experienced higher hypertension than moderate drinkers (with marginal significance: $p=.054$), and excessive drinkers experienced higher hypertension than moderate drinkers ($p=.002$). In contrast, among underrepresented older adults, hypertension levels did not vary significantly by drinking group. Graphical results clarified that the lack of drinking effects among underrepresented older adults reflected that they had similarly elevated hypertension across all three drinking groups, whereas the White older adults only had comparably elevated hypertension in the excessive-drinker group. These findings suggest that the positive health effects of moderate drinking apply primarily to White older adults. Our poster will discuss potential explanations for the apparent lack of health benefits of safe-drinking practices among underrepresented older adults.

LONELINESS AND ISOLATION AS BARRIERS TO MENTAL HEALTH SERVICES IN A RURAL COMMUNITY

Robert Maiden,¹ Danielle Gagne,² and Bert Hayslip,³
 1. Alfred University, Alfred, New York, United States,

2. Alfred University, Alfred University, New York, United States, 3. University of North Texas at Denton, Denton, Texas, United States

As America grapples with COVID-19, issues regarding mental health have been of rising concern, particularly among those who are isolated. According to the May 2021 American Perspectives Survey, “Americans report having fewer close friendships than they once did, talking to their friends less often, and relying less on their friends for personal support.” Additionally, 49% have three or fewer close friends in 2021, compared to 27% in 1990. 17% have no friends in their core social network. Loneliness has been associated with physical and mental health risks. We sought to explore whether loneliness was also a barrier to seeking mental health services. 90 surveys were collected from rural New York. Respondents were aged 51 to 90, Caucasian (96.6%), and female (73.3% vs, 26.7%). Overall, 34.8% said they lived alone. 29.2% would seek mental health services for feelings of loneliness, while 75.4% would do so if isolated from family. Those who felt detached or isolated from others were significantly less likely to seek help from a counselor ($r = -0.25$) or MD ($r = -0.37$). Isolation also negatively related to measures on the resiliency scale (Purpose: -0.22 , Perseverance: -0.33 , being ok alone: -0.32), and positively related to depression ($r = .65$). Those scoring higher on the “okay with being alone” scale had an increased likelihood of seeking counseling ($r = 0.22$). Thus, isolation and loneliness are complex topics. Intervention ought to be based on perceptions of being alone. Further research is needed.

LONELINESS, SOCIAL SUPPORT, AND PSYCHOLOGICAL WELLBEING AMONG OLDER ADULTS

Poshan Dahal,¹ Eva Kahana,² Tirth Bhatta,³ and Polina Ermoshkina,²
 1. Case Western Reserve University, Shaker Heights, Ohio, United States, 2. Case Western Reserve University, Cleveland, Ohio, United States, 3. University of Nevada, Las Vegas, Nevada, United States

Social support in old age has been linked to psychological wellbeing outcomes, such as depressive symptoms. However, insufficient attention has been paid to implications of social support for different domains of psychological wellbeing. In this study, we explored these associations among 797 older adults (mean age = 78.61 years) living in a retirement community in Florida from the ECRC study. Our findings show that measures of social support and connectedness have varying influences on psychological wellbeing. Loneliness was associated with lower life satisfaction ($b = -1.12$, $p < 0.001$) and higher depressive symptoms ($b = 3.52$, $p < 0.001$). Higher self-rated social support was associated with higher life satisfaction ($b = 1.66$, $p < 0.001$) but did not predict depressive symptoms. Depressive symptoms, however, were significantly higher ($b = -1.45$) among individuals who reported that they don't have anyone who they can turn to if they feel lonely and want to talk. Feeling lonely also predicted lower positive affects among these older adults ($b = -0.65$, $p < 0.001$). Similarly, loneliness also predicted higher negative affects ($b = 1.28$, $p < 0.001$). Negative affects were also significantly higher among women ($b = -1.15$, $p < 0.001$) but lower among those who were living alone ($b = -1.06$, $p < 0.001$). Overall, our findings underscore the importance of social support and

connectedness for psychological wellbeing in later life. This finding is consistent with prior research demonstrating significance of social support in later life for the overall psychological wellbeing of the older adults.

LONGITUDINAL ASSOCIATIONS OF PHYSICAL TOUCH WITH LONELINESS AMONG OLDER ADULTS

Taylor Brown,¹ Reese Giddens,² and Stephanie Wilson,³ 1. *Southern Methodist University, Dallas, Texas, United States*, 2. *Southern Methodist University, Southern Methodist University, Texas, United States*, 3. *Southern Methodist University, DALLAS, Texas, United States*

Older adults in the US face heightened risks for social disconnection, and the COVID-19 pandemic has further exacerbated this crisis. Physical touch is a key dimension of social connection that uniquely predicts physical and mental health benefits. However, most studies have been limited by cross-sectional designs, and no prior work has examined the long-term effects of physical touch on loneliness. To investigate the prospective association between physical touch and loneliness among older adults, this study utilized data from 1626 older adults (Mean age = 68, range = 57-85) who participated in Waves 1 and 2 of the National Social Life, Health, and Aging Project (NSHAP). Participants reported on their loneliness and physical contact with family and friends, as well as with pets, at both waves. Results revealed that more frequent physical contact with family and friends predicted larger decreases in loneliness over the subsequent five years ($p < .0001$), controlling for age, race, gender, health conditions, marital status, frequency of social interaction, and baseline levels of loneliness. Physical contact with pets had no unique effect ($p = .136$). To further assess directionality, models tested whether lonelier people experienced decreased touch over time, and the effects were null ($p > .250$). Taken together, this longitudinal study is the first to identify the unique contribution of human physical touch to prospective changes in loneliness, beyond the well-established effects of covariates, including social interaction frequency. Touch represents a compelling mechanism by which social isolation may lead to loneliness, which in turn raises risks for poor health and premature mortality.

MEASURING MINDFULNESS: ASSESSING THE UTILITY OF THE FFMQ IN THE OLDER VETERANS WITH DEMENTIA AND THEIR CAREGIVERS

Brian Clawson,¹ Phoebe Block,² Daniel Durkin,³ Amber Collins,¹ Lindsey Jacobs,¹ and Michelle Hilgeman,⁴ 1. *Tuscaloosa VA, Tuscaloosa, Alabama, United States*, 2. *Battle Creek VA Medical Center, Battle Creek, Michigan, United States*, 3. *The University of Mississippi, University, Mississippi, United States*, 4. *Tuscaloosa VA Medical Center, Tuscaloosa, Alabama, United States*

Mindfulness is increasingly popular as a low cost, convenient, and accessible way to address mental health and chronic health conditions. Despite its popularity, best practices in measuring mindfulness in clinical settings and intervention research are still being defined. The Five Facet Mindfulness Questionnaire (FFMQ-15) measures mindfulness traits; however, its use has been limited in older adults, those with dementia, and caregivers. Method: Caregivers (N=82) and veterans with dementia (N=62) enrolled in a randomized

pilot intervention study completed the 15-item FFMQ at baseline, 6-month, and 12-month assessments. Veterans were mostly male (98%), White/Caucasian (65%), and living with a partner/spouse (79%). Caregivers (M=65 years old) were mostly female (89%) and White/Caucasian (66%). FFMQ response options were simplified to a 3-point Likert-scale for individuals with dementia (0=rarely true to 2=often true). Results: Internal consistency statistics (Cronbach's alphas) at the scale-level were acceptable among caregivers at baseline and 6-months (.71-.75) but questionably reliable at 12-months (.59, N=46). For individuals with dementia, the simplified version of the FFMQ (with 3 response options) achieved questionable reliability at baseline (.57, N=56) and 6-months (.67, N=32), but improved to acceptable at 12-month assessments (.75, N=15), after significant attrition. Conclusion: Researchers should apply caution when using the FFMQ total score with caregivers and those with cognitive impairments. Though simplified response options eased administration, utility of the tool may be limited in those who are more impaired. Before mindfulness measures can be used meaningfully, reliability of available tools like the FFMQ-15 need to be examined in more diverse samples.

MEASURING UTILITY OF VASS ELDER MISTREATMENT SCREENER WITHIN COMMUNITY DWELLING U.S. CHINESE OLDER ADULTS

Natalie Tuseth,¹ XinQi Dong,² and Stephanie Bergren,² 1. *Rutgers Institute for Health, Health Care Policy and Aging Research, New Brunswick, New Jersey, United States*, 2. *Rutgers, New Brunswick, New Jersey, United States*, 3. *Rutgers University, New Brunswick, New Jersey, United States*

Elder mistreatment (EM) is often underreported, making potential screening a valuable tool. There is limited literature on the screening utility, especially for minority populations. This abstract aims to study sensitivity and specificity of a commonly used 10-point EM screener compared to a detailed EM questionnaire among Chinese older adults. This study used data from a representative sample of 3,157 community-dwelling U.S. Chinese older adults 60+. Chi-squared test was conducted between VASS 10-questionnaire screener and EM measured by 56 items on psychological, physical and sexual mistreatment, caregiver neglect and financial exploitation subtypes. Sensitivity and specificity was calculated using the Bayes Theorem. In this sample, average age was 72 and 59% female. 637 (20.30%) reported any EM while 475 (15.14%) older adults screened positive for EM. Of participants reporting any EM, 365 (57.30%) did not screen positive for EM. The screener had a sensitivity of 42.70% and specificity of 91.88% for all EM subtypes. Gaps between reported EM and negative EM screener is smaller in psychological (sensitivity 72.85%, specificity 91.07%) and physical (sensitivity 63.64%, specificity 86.66%) EM subtypes, but much larger in financial exploitation (sensitivity 34.60%, specificity 86.85%) and neglect (sensitivity 14.11%, specificity 84.75%). The VASS screener demonstrates poor sensitivity but acceptable specificity rate for any EM. The screener showed better sensitivity and specificity for physical and psychological mistreatment, but performed worse for more common forms of mistreatment like financial exploitation and neglect. Modifying this screener may improve sensitivity and specificity in identifying EM.

MULTIFACETED SLEEP HEALTH SCORE IS ASSOCIATED WITH FRAILITY IN A NATIONAL SAMPLE OF OLDER ADULTS IN TAIWAN: SEX MATTERS

Tuo Yu Chen,¹ Soomi Lee,² and Orfeu Buxton,³ 1. *Taipei Medical University, Taipei, Taipei, Taiwan (Republic of China)*, 2. *University of South Florida, Tampa, Florida, United States*, 3. *The Pennsylvania State University, The Pennsylvania State University, Pennsylvania, United States*

Although individual sleep characteristics are related to frailty, these characteristics do not occur separately. A multidimensional measure of sleep might provide a better estimation of frailty compared to isolated sleep characteristics. This study investigated the association of a multidimensional measure of sleep health with frailty and examined whether such relationship differed by sex. Data were from the Taiwan Longitudinal Study on Aging (2011), a survey with a nationally representative sample of Taiwanese older adults (N=2,015). Frailty was defined using the Fried-criteria. Self-reported sleep during the past month was used to conceptualize the five sleep health dimensions in the SATED model (satisfaction-alertness-timing-efficiency-duration; higher scores representing better sleep health). Their relationship was estimated using logistic regression analysis adjusting for sociodemographic (age, sex, education), health (chronic conditions, cognitive function, pain, depressive symptoms [excluding items overlapping with frailty and sleep]), and lifestyle (drinking, smoking, exercise) characteristics. The results showed that having a better sleep health composite score was significantly related to lower odds of being frail in both sexes adjusting for sociodemographic information. Such effect remained significant among females but not males after adding health and lifestyle characteristics to the models. Sleep satisfaction and daytime alertness in both sexes and sleep duration among females were significantly associated with frailty adjusting for sociodemographic information. Only alertness among males was significantly related to frailty in model with all covariates. Our findings show that having a better sleep health across multiple dimensions is related to a lower risk of being frail, and the association differs by sex.

NUTRITION PROGRAM IMPROVES HEALTH-RELATED OUTCOMES OF NON-DIABETIC ELDERLY AT NUTRITIONAL RISK

Cory Brunton,¹ Luis Carlos Venegas-Sanabria,² Gabriel Gomez,³ Juan Diego Misas,³ and Suela Sulo,⁴ 1. *Abbott Nutrition, Columbus, Ohio, United States*, 2. *Pontificia Universidad Javeriana, Bogota, Distrito Capital de Bogota, Colombia*, 3. *Abbott Nutrition, Bogota, Distrito Capital de Bogota, Colombia*, 4. *Abbott Nutrition, Chicago, Illinois, United States*

Malnutrition or its risk affects up to 1 in 3 older adults receiving outpatient care post a hospitalization or for chronic disease management. Although malnutrition poses a negative burden on someone's recovery and health preservation, it can be effectively addressed through cost-effective nutrition interventions delivered as comprehensive quality improvement programs (QIPs) aiding to advance healthcare professional's nutrition education/training and improve quality of care for at-risk/malnourished individuals. Although evidence from US and Europe demonstrates nutrition-focused QIPs are

effective in delivering high-quality nutrition care and improve health outcomes of outpatients at-risk/malnourished, to date, no evidence has been reported from Latin American countries. We assessed effectiveness of a comprehensive, nutrition-focused QIP in a Colombian outpatient clinic. Between 09/2019-03/2020, 504 (of total 618) QIP participants were classified at-risk/malnourished and non-diabetics. Participants were followed for 90-days either in-person or via telehealth mechanisms (during COVID-19-imposed lockdown period). QIP interventions included healthcare professional nutrition education; QIP participant continuous nutrition and exercise counselling and 60-day supply of oral nutrition supplement (Ensure®, Abbott). QIP participants were 69% female, with >2 comorbidities, and mean age of 73. Improvement or maintenance of good mental health/well-being, frailty status, cognition and quality of life was reported for 90.7% (456/503), 87.3% (407/466), 86.7% (405/467) and 47% (237/504) participants, respectively (p-values<0.05). Results support QIP effectiveness in driving improved health-related outcomes for non-diabetic, at-nutritional-risk participants. These findings highlight the importance of nutrition-focused QIPs with ONS for older adults during their recovery phase post a recent hospitalization and/or for chronic disease management.

OLDER ADULTS AND FAMILY PERSPECTIVE ON INTERACTION WITH NURSES IN HOSPITAL: THE ROLE OF MUTUAL UNDERSTANDING

Orly Tonkikh,¹ Nurit Gur-Yaish,² Ksenya Shulyaev,³ Amos Rogozinski,⁴ and Elena Siegel,⁵ 1. *University of California Davis, Sacramento, California, United States*, 2. *Oranim Academic College of Education, Haifa, HaZafon, Israel*, 3. *Faculty of Social Welfare and Health Science, University of Haifa, Haifa, Hefa, Israel*, 4. *University of Haifa, Neshet, HaZafon, Israel*, 5. *University of California, Davis, Sacramento, California, United States*

Optimal nurse-patient-family interaction is required to provide effective family-centered care for hospitalized older adults and their families. This qualitative descriptive study explored nurses' interactions with older adult patients and their family members during acute hospitalization. We used semi-structured interviews to collect data from a convenience sample of nine dyads of older adults (aged 62-85) and family members (7 children and 2 spouses) who accompanied them during an acute hospitalization in medical or surgical units. Interviews were performed via Zoom beginning in December 2020 until August 2021, 1-12 months after the hospitalization. Thematic analysis was used to inductively capture key patterns in data. Both patients and family members revealed three factors contributing to the way nurses interact with patients and families: (1) nurses' recognition and understanding of patients' needs for family members' presence and participation in care; (2) nurses recognition that family members expect dedication of attention, beyond nurses' focus on patient's care (3) patient and family members' recognition of the extreme workload of nursing staff. Participants described a range of informal approaches used by both nurses and families to address each other's needs. Both patients and families emphasize the benefits and costs of nurses engaging in "exceptional" interactions with patients and families considering structural characteristics such as establishing a

personal relationship or accepting family visits beyond the rules. The findings provide direction for further exploration of hospitalization structures and processes needed to support optimal nurses' interactions with families accompanying older adults and family-centered approach training in acute care context.

OLDER BLACK AMERICANS AND DEPRESSIVE SYMPTOMS DURING THE COVID-19 PANDEMIC

David Chae,¹ Connor Martz,² Kara Chung,¹ Roland Thorpe,³ and Karen Lincoln,⁴ 1. *Tulane University, Tulane University, Louisiana, United States*, 2. *Tulane University, New Orleans, Louisiana, United States*, 3. *Johns Hopkins Bloomberg School of Public Health, Johns Hopkins Bloomberg School of Public Health, Maryland, United States*, 4. *University of Southern California, Los Angeles, California, United States*

Black Americans have experienced multiple health threats during the COVID-19 pandemic, including greater risk of infection compared to Whites. In addition, older adults are more susceptible to worse disease consequences including hospitalization and mortality compared to those who are younger. Racism and economic costs are additional public health crises during this time that have disproportionately impacted Black Americans. Using data from the Uncovering COVID-19 Experiences and Realities (UnCOVER) Study, we examined depressive symptoms in relation to: (1) worry/fear of COVID-19; (2) work loss among household members (being laid off, reduced work hours); and (3) vicarious racism, a particularly salient source of psychosocial stress during the COVID-19 pandemic, including hearing about or seeing acts of racism committed against other race group members. Participants were Black Americans aged 50 years or older ($n=300$) from five cities (Atlanta, Chicago, Los Angeles, New Orleans, and New York) from May-July 2020. Depression was assessed using the Patient-Reported Outcomes Measurement Information System Short Form. In multivariable linear regression models, all three public health threats were significantly associated with depressive symptoms. When in the model simultaneously, worry/fear of COVID-19 ($b=0.30$, $SE=0.12$, $p<0.01$) and vicarious racism ($b=0.62$, $SE=0.15$, $p<0.001$) showed positive associations; work loss was no longer statistically significant ($b=0.62$, $SE=0.43$, $p=0.15$). When added, the corresponding three-way interaction term was significant ($b=0.12$, $SE=0.04$, $p<0.01$). Synergistic epidemics ("syndemics") among older Black Americans amplify mental health tolls. Multi-pronged public health strategies are required to address depression in this population.

PERCEIVED EVERYDAY DISCRIMINATION AND C-REACTIVE PROTEIN INFLUENCE ON COGNITION OF OLDER BLACK ADULTS

Sydney Kirven,¹ Heather Farmer,² and Amy Thierry,³ 1. *Xavier University of Louisiana, New Orleans, Louisiana, United States*, 2. *University of Delaware, Newark, Delaware, United States*, 3. *Xavier University of Louisiana, Xavier University of Louisiana, Louisiana, United States*,

Black adults and women are more likely to experience serious cognitive decline in older age than their white and male counterparts. Evidence suggests perceived discrimination

is associated with poor cognition in older adults, though the mechanisms remain unclear. Perceived discrimination has been linked to elevated inflammatory markers, such as C-reactive protein (CRP), which increases risk for worse cognitive functioning. Yet, little research has investigated whether CRP is implicated in the association between discrimination and cognition among Black older adults or if this relationship differs by gender. Using 2006-2016 data from Black adults ≥ 65 years old ($N=1343$) in the nationally representative Health and Retirement Study, random effects linear regression models (1) tested the association between discrimination and cognitive functioning; (2) explored whether this relationship differed for women and men; and (3) assessed whether elevated CRP mediated the association between discrimination and cognitive functioning. More frequent discrimination was associated with worse cognitive functioning ($b= -0.24$, $SE=0.11$, $p<0.05$), though gender did not moderate this relationship. Elevated CRP was significantly associated with worse cognitive functioning ($b= 0.40$, $SE=0.18$, $p<0.05$). Discrimination remained statistically significant in this model, indicating no mediation by CRP. Of note, inclusion of depressive symptoms and cardiometabolic conditions accounted for the association between both discrimination and CRP with cognitive functioning. These findings demonstrate the need for more within-group research on older Black adults documenting the complex relationship between discrimination, inflammation, and cognitive health. This approach will provide greater understanding of the biopsychosocial mechanisms underlying disparities in cognitive functioning in Black adults.

PERCEIVED NEIGHBORHOOD DISORDER, SOCIAL COHESION, AND DEPRESSIVE SYMPTOMS AMONG SPOUSAL CAREGIVERS

Yeon Jin Choi, and Jennifer Ailshire, *University of Southern California, Los Angeles, California, United States*

Most prior research on caregivers' mental health focused on individual or household factors, we know much less about the influence of neighborhood factors on mental health of spousal caregivers. The current study fills the gap in our knowledge by examining the association of neighborhood characteristics (i.e., perceived neighborhood disorder and neighborhood social cohesion) and depressive symptoms among spousal caregivers. We used data from 2006 to 2016 waves of the Health and Retirement Study, which includes 2,362 spousal caregivers. Negative binomial regression models were estimated to examine the association of perceived neighborhood disorder and neighborhood social cohesion with depressive symptoms. A greater perceived neighborhood disorder was associated with higher CES-D scores, which indicates more depressive symptoms. On the other hand, a higher level of neighborhood social cohesion was associated with lower CES-D scores. When they were included in the same model, the association between neighborhood disorder and depression disappeared, while respondents who reported higher levels of neighborhood social cohesion continue to exhibit lower CES-D scores than those lived in less cohesive neighborhoods. This study highlights the importance of neighborhood contexts in understanding caregivers' well-being. Findings of this study suggest that neighborhood social cohesion may attenuate the negative

effects of neighborhood disorder. Therefore, enhancing positive characteristics of the neighborhood may promote well-being of spousal caregivers.

PERCEPTIONS OF MEDICAL CANNABIS PACKAGING AND LABELING AMONG MIDDLE-AGED AND OLDER CANADIANS

Melissa O'Connor,¹ Vanessa Christiuk,² and Megan Pedersen,³ 1. *North Dakota State University, Moorhead, Minnesota, United States*, 2. *Eloski Health Centre, Fargo, North Dakota, United States*, 3. *North Dakota State University, Fargo, North Dakota, United States*

The use of cannabis for therapeutic purposes is becoming more popular in many countries, including the United States and Canada. In Canada, middle-aged and older adults make up the largest proportion of medical cannabis users. Canadian legislation mandates that medical cannabis be packaged in plain-looking containers with small labels, childproof caps, and required health warnings. This is meant to standardize the way cannabis products are distributed, as well as protect children from accidental ingestion. However, there is limited research on how these regulations affect cannabis users over age 45. In the present study, residents of Winnipeg, Manitoba, Canada aged 45 and older ($n=40$) were surveyed regarding their experiences with medical cannabis packaging and labeling. Half of the participants (50%) felt they had a hard time opening their medical cannabis container. A majority (60%) thought having an easy-open lid would be helpful. Most participants (78%) reported experiencing difficulties reading the label on their container, and 75% thought it would be helpful to have a printout of the label in a larger font. In addition, 89% of participants who took more than one kind of medical cannabis favored a symbol on their medication bottle that would indicate the type of medical cannabis contained inside. Implications for policy makers and future research are discussed.

PERCEPTIONS OF PARTNER COGNITIVE ABILITY DURING THE COVID-19 PANDEMIC

Celinda Reese-Melancon,¹ Jennifer Margrett,² Dan Russell,² Rachael Turner,³ Erin Harrington,⁴ Lauren Stratton,² and Jyoti Savla,⁵ 1. *Oklahoma State University, Oklahoma State University, Oklahoma, United States*, 2. *Iowa State University, Ames, Iowa, United States*, 3. *Oklahoma State University, Stillwater, Oklahoma, United States*, 4. *Pennsylvania State University, University Park, Pennsylvania, United States*, 5. *Virginia Tech, Blacksburg, Virginia, United States*

Media reports provide anecdotal evidence of increased forgetfulness during the COVID-19 pandemic (Cushing, 2021; Purtill, 2020). Scientific evidence suggests social isolation can impact on cognition (Evans et al., 2018), but the question remains whether those living with a partner experience similar deficits. The present study examined whether middle-aged and older adults' perceptions of their own and their partner's memory abilities were related to self-reported impact of the pandemic on daily life (e.g., limited social interactions, delayed health care, and disruption to routine). In a sample of 80 married individuals (49% female; age range 40-86 years), we found that participants' beliefs about the impact of the

pandemic on daily life and their depression ratings significantly predicted ($p<0.05$) their perceptions of their partner's prospective memory abilities. Specifically, pandemic impact on daily life predicted 9.3% of the variance in participants' reported perceptions of their partners' prospective memory abilities, and participant depression ratings predicted an additional 5.1% of the variance. Surprisingly, these variables did not predict perceptions of participants' own cognition or perceptions of partners' retrospective memory abilities. In sum, people who reported greater impact of the pandemic on their lives were more likely to believe that their partner frequently forgot to carryout prospective memory intentions (e.g., failed to pass along a message or take medication), and depression further clouded their perception of their partner's cognition. These findings should be extended to consider relationship quality and whether individuals consider their partners a reliable source of external memory support during times of life disruption.

PERCEPTIONS ON OWN AGING: COMPARISONS BETWEEN YOUNG ADULTS WITH AND WITHOUT CAREGIVING EXPERIENCE

Phoebe Clark,¹ Vanessa Cuppari,² Matthew Picchiello,³ Michiko Iwasaki,⁴ and Andrew Futterman,⁵ 1. *Loyola University MD, Gaithersburg, Maryland, United States*, 2. *Loyola University Maryland, Baltimore, Maryland, United States*, 3. *Washington University in St. Louis, St. Louis, Missouri, United States*, 4. *Loyola University MD, Department Of Psychology, Maryland, United States*, 5. *Loyola University MD, Loyola University MD, Maryland, United States*

Although informal caregiving for older adults (OAs) can increase knowledge and awareness about one's own aging (Pope, 2013), it can also negatively impact caregivers' physical health and emotional wellbeing (AARP & NAC, 2020) and have spillover effects on school, work, and marriage (Dellmann-Jenkins & Blankemeyer, 2009). Despite the recent trend of family caregiving for OAs by young adults (YAs), research about these young caregivers is scarce. The present study focused on YAs' perceptions on aging. We hypothesized that YAs who provided at least three months of caregiving tasks for OAs would hold more awareness and negative perceptions on their own aging, as measured by a modified version of the Brief Aging Perceptions Questionnaire (Sexton et al., 2014), compared to those who did not. We recruited 234 YAs between the ages of 18 - 40 ($M_{age} = 29.78$, $SD_{age} = 4.83$; 59% White; 65.4% male) and had them complete a survey via Amazon Mechanical Turks. About one third (32.1%) had caregiving experience. Results of independent t-tests revealed that caregivers scored higher on awareness of aging [$t(229) = 6.950$, $p < .001$, $d = .865$] and negative consequences/control [$t(231) = 6.528$, $p < .001$, $d = .927$]. Scores of positive consequences/control did not differ between the two groups. Our findings indicate the need for psychological interventions designed to help young caregivers integrate their caregiving experiences with less negative aging perceptions. Future research should examine the direct effects of caregiving experience on perceptions of aging between young and middle-aged adults.

PHASE 2B STUDY OF AN AD26.RSV.PREF VACCINE FOR PREVENTION OF RSV-MEDIATED RESPIRATORY TRACT DISEASE IN OLDER ADULTS

Ann Falsey,¹ Kristi Williams,² Efi Gymnopoulou,³ Stephan Bart,⁴ John Ervin,⁵ Els De Paepe,³ Christy Comeaux,⁶ and Esther Heijnen,⁶ 1. *University of Rochester School of Medicine, Rochester, NY, USA, Rochester, New York, United States*, 2. *Janssen Research and Development, Spring House, PA, USA, Spring House, Pennsylvania, United States*, 3. *Janssen Infectious Diseases, Beerse, Belgium, Beerse, Antwerpen, Belgium*, 4. *Optimal Research, LLC/Synexus Clinical Research/AES, Woodstock, MD, USA, Rockville, Maryland, United States*, 5. *AMR Kansas City, Kansas City, MO, USA, Kansas City, Missouri, United States*, 6. *Janssen Vaccines & Prevention BV, Leiden, The Netherlands, Leiden, Zuid-Holland, Netherlands*

Respiratory syncytial virus (RSV) may cause serious lower respiratory tract disease (LRTD) in older adults, and there is currently no licensed vaccine. CYPRESS (NCT03982199) is a randomized, double-blind, placebo-controlled Phase 2b proof-of-concept trial of an Ad26.RSV.preF-based vaccine for the prevention of RSV-mediated LRTD in older adults. Adults aged ≥ 65 years were randomized 1:1 before the RSV season to receive Ad26.RSV.preF-based vaccine or placebo. Acute respiratory infection symptoms were collected through a patient eDiary and/or clinician assessment until the end of the RSV season. The primary endpoint was the first occurrence of RTPCR-confirmed RSV-mediated LRTD according to any of 3 case definitions: (1) ≥ 3 symptoms of lower respiratory tract infection (LRTI), (2) ≥ 2 symptoms of LRTI, or (3) ≥ 2 symptoms of LRTI or ≥ 1 symptom of LRTI with ≥ 1 systemic symptom. Immunogenicity was assessed in a subset of approximately 200 participants. A total of 2891 participants in each study arm received study treatment. Vaccine efficacy was 80% (94.2% CI, 52.2-92.9%), 75% (50.1-88.5%), and 69.8% (43.7-84.7%) for case definition 1, 2, and 3, respectively (all $P < 0.001$). In the vaccine arm, geometric mean fold increase in antibody titers 14 days after vaccination was 13.5 for RSV neutralizing antibodies and 8.6 for RSV prefusion F-specific binding antibodies, and median frequency of RSV-F-specific $INF\gamma$ T-cells increased from 34 to 444 SFC/ 10^6 PBMC; no relevant changes were observed in the placebo arm. The Ad26.RSV.preF-based vaccine was highly effective against RSV-mediated LRTD through the first RSV season and elicited robust immune responses in older adults.

PHYSICAL ACTIVITY PROGRAMMING FOR OLDER ADULTS IN ASSISTED LIVING: CONTEXTUAL FACTORS TO CONSIDER

Katelyn Webster, and Janet Larson, *University of Michigan School of Nursing, Ann Arbor, Michigan, United States*

Sedentary behavior may adversely affect physical and cognitive health of older adults in assisted living (AL). Replacing sedentary behavior with light physical activity (PA) could help them maintain functional abilities and independence. We interviewed AL residents to obtain their guidance regarding the implementation of an intervention to reduce sedentary behavior. Here we report the results of a thematic analysis exploring contextual factors that may influence intervention implementation. We interviewed 20 residents (mean age 83.1; 60% women) and identified 7 themes.

The first was attitudes and beliefs about PA. Most residents believed PA was important, but some lacked motivation or confidence to perform PA. Another theme was attitudes and beliefs about aging, as some residents felt discouraged about aging and uncertainty about how much PA they could safely perform. Abilities of AL residents was seen as an important consideration. It was noted that residents have a wide range of abilities and this could present challenges in planning a PA program appropriate for all residents. Social influences for PA should be considered, as residents may find encouragement from family or other residents. Space for being active is another factor because it is typically limited within AL. We found that some residents wanted more challenging exercise classes than currently provided by their facility. Finally, residents described limited opportunities for PA due to the nature of the AL environment. This thematic analysis brings attention to important factors that could influence the implementation of PA interventions with the AL population.

PREDICTION OF COVID-19 STRESS AMONG COMMUNITY DWELLING OLDER ADULTS: THE ROLE OF ANXIETY AND RESILIENCY

Geffre Jean Francois, Dawn Carr, and Natalie Sachs-Ericsson, *Florida State University, Tallahassee, Florida, United States*

Worldwide, the COVID-19 pandemic has been an unparalleled source of stress. Older adults with anxiety are vulnerable to higher levels of stress during the pandemic. However not all older adults with anxiety will experience severe stress; resiliency may decrease such negative outcomes. There have been few, if any, longitudinal studies that followed older adults before and during the pandemic. Our data of community dwelling older adults (aged 60-92) is unique in that it allowed for an investigation of psychological variables that increase and decrease negative outcomes during the pandemic. Our longitudinal study examined the influence of pre-pandemic anxiety and resiliency on the severity of COVID related stress. Methods: The pre-pandemic data was obtained in September 2018, and the pandemic data was collected in June 2020. In the baseline survey we obtained measures of anxiety and resiliency. During the pandemic we measured the severity of COVID related stressors. We hypothesized that anxiety would predict higher level of COVID-stress, whereas resiliency would be associated with decreased severity of COVID-stress. Further we predicted that resiliency would attenuate the association between anxiety and COVID-stress. Results: Using OLS regression, we found that anxiety predicted higher COVID-stress, whereas resiliency predicted lower COVID-stress. However, resiliency did not moderate the association between anxiety and COVID-stress. Conclusion: Older adults are subject to many unavoidable negative life events, such as death of family members and chronic health problems. Resiliency may help buffer against such adversities. Development of intervention programs to enhance resiliency may increase psychological resources and foster healthy aging.

PROBLEM-DRINKING ACROSS THE LIFESPAN: CROSS-SECTIONAL VERSUS LONGITUDINAL EFFECTS AMONG MIDLIFE AND OLDER ADULTS

Annabel Kady,¹ Yimei Li,² Angelo DiBello,² and Matthew Lee,² 1. *Rutgers University, Baltimore, Maryland,*

United States, 2. Rutgers University, Piscataway, New Jersey, United States

When considering problem drinking from a lifespan-developmental perspective, an often-stated premise is that problem drinking escalates during adolescence, peaks around early young adulthood, and then declines throughout the remainder of the lifespan. However, while there is a strong empirical basis for such changes throughout adolescence and young adulthood, the notion of continued declines throughout midlife and older adulthood is less firmly established and based primarily on cross-sectional data. Thus, this study contrasted cross-sectional versus longitudinal age effects on problem-drinking changes across the lifespan, with particular focus on midlife and older adulthood. Analyses used data from a large, two-wave, U.S.-representative sample. We generated descriptive “porcupine figures” graphically depicting both cross-sectional and longitudinal age effects simultaneously, and we estimated mixed-ANOVAs to partition, test, and contrast cross-sectional versus longitudinal age effects. As expected, analyses confirmed the well-known rise and fall of problem drinking across young adulthood in both cross-sectional and longitudinal age effects. In contrast, in midlife and older adulthood, only cross-sectional age effects were consistent with the notion of continued age-related declines throughout these ages, whereas the longitudinal data showed a mixture of stability and escalation at these ages. Age-confounded cohort effects are one plausible explanation for how cross-sectional data can lead to spurious conclusions about developmental change. By potentially yielding a more accurate understanding of lifespan-developmental change in midlife and older adulthood, findings like ours could help guide lifespan-developmentally-informed interventions for midlife and older-adult problem drinkers; an objective of increasing importance in light of the ongoing aging of the U.S. population.

PSYCHOLOGICAL IMPACT OF COVID-19 PANDEMIC ON FRONTLINE RESPONDERS AND STUDENTS IN TRAINING

Andrew Revell,¹ and Mitchell Gauvin,² 1. *University of Massachusetts Dartmouth, University of Massachusetts Dartmouth, Massachusetts, United States, 2. University of Massachusetts Dartmouth, North Dartmouth, Massachusetts, United States*

Medical personnel have been in the frontlines of the pandemic leading to increased levels of stress and an impact on mental health. Risks may include, but are not limited to, pronounced burnout (Shechter et al., 2020), vicarious trauma, and post-traumatic stress disorder. The goal of this investigation was to gain insight on the psychological effects that the pandemic had on both frontline responders (EMTs and emergency room staff) and students in clinical training. Emerging adults and adult participants (N=150; ages 18-46; 70.4% ages 18-24) were recruited through the introductory psychology subject pool, community healthcare, and social media. Linear regression and means testing were employed to assess differences between current frontline workers and future workers on the Depression, Anxiety, and Stress Scale (DASS-21; Lovibond, 1995) on irritability, sleep, covid-19 positive presence, concentration, and other mental health factors. Hierarchical linear regression, controlling for age, indicated

higher anxiety subscale scores ($b=2.49$, $p=.008$) and higher stress subscale scores ($b=2.25$, $p=.035$) were present on the DASS-21 for women. Dichotomous means testing indicated higher anxiety, stress, and depression levels for those who also reported a significant change in sleep habits ($p < .001$) and for those who reported being more irritable on their days off ($p < .001$) during the pandemic. Students in training (37.7%) indicated interest in considering a different career path ($r = .302$, $p = .02$). Future studies should examine these dynamic relationships among mental health factors among healthcare professionals and the implications for training the next generation.

PSYCHOSOCIAL PREDICTORS OF PSYCHOLOGICAL WELL-BEING DURING THE COVID-19 PANDEMIC

Yeon Ji Ryou,¹ Gina Lee,¹ Rotem Arieli,¹ Peter Martin,¹ Shinae Choi,² Jinmyoung Cho,³ and Melinda Heinz,⁴ 1. *Iowa State University, Ames, Iowa, United States, 2. The University of Alabama, Tuscaloosa, Alabama, United States, 3. Baylor Scott & White Health Research Institute, Temple, Texas, United States, 4. Upper Iowa University, Fayette, Iowa, United States*

People worldwide have been largely affected by the COVID-19 outbreak. In addition to worries about physical health, it also causes concerns about psychological and mental health. This research aims to explore predictors affecting psychological well-being during the pandemic using the 2018 Health and Retirement Study (HRS) RAND longitudinal data (N = 42,233) and the 2020 HRS COVID-19 module (N = 3,266). Demographics (i.e., gender, age, and education), psychosocial (i.e., personality traits), and health (i.e., comorbidity) variables were included in multivariate logistic and ordinary least square regression analyses predicting feeling “overwhelmed,” “stressed,” and “lonely” during the pandemic. Our results indicated that neuroticism was positively associated with all outcomes. Women were more likely to feel overwhelmed, stressed, and lonely compared to men. Age negatively predicted the overwhelmed and stressed feelings. Furthermore, the effect of depressive symptoms in 2012, 2014, 2016, and 2018 on psychological well-being was assessed by conducting a latent growth curve model. Findings indicate that initial level and increasing change of depressive symptoms over four-time points (waves 11-14) were positively related to psychological feelings. A higher level of depressive symptoms at the initial level of 2012 and increasing reports of depression symptoms predicted higher rates of being stressed, feeling overwhelmed, and lonely during the COVID-19 pandemic. The results have implications for future research and interventions that should target the emotional antecedents and consequences of pandemics.

QUALITY OF LIFE AND WELLBEING IN PERIPHERAL ARTERIAL DISEASE: A QUALITATIVE STUDY

Mary Byrnes,¹ Heather Dillaway,² Bryan Aaron,³ Alisha Heximer,⁴ Valeria Valbuena,⁵ Matthew Corriere,⁶ and Nicholas Osborne,⁶ 1. *University of Michigan, Ann Arbor, Michigan, United States, 2. Wayne State University, Wayne State University, Michigan, United States, 3. University of Michigan Medical School, University of Michigan Medical School, Michigan, United States, 4. University of Michigan, University of Michigan Medical School, Michigan, United States, 5. University of Michigan, University of Michigan Medical School, Michigan, United States, 6. University of Michigan, University of Michigan Medical School, Michigan, United States*

States, 5. *University of Michigan, University of Michigan, Michigan, United States*, 6. *University of Michigan, University of Michigan, Michigan, United States*

Peripheral arterial disease (PAD) is a vascular condition disproportionately affecting adults > 60 and the leading cause of disability for adults > 50. Because PAD is marked by severe leg pain and sometimes lower extremity amputation, quality of life (QOL) and wellbeing may be compromised however, we understand little about these constructs in this population. Furthermore, surgical care providers lack a comprehensive understanding of how individuals think about wellbeing and what is important to individuals during surgical care. We conducted a qualitative photographic elicitation study (n = 60) in one academic multidisciplinary PAD clinic to understand specific aspects of QOL of older individuals with PAD. Guided by interpretive description, a methodology pioneered in nursing, we analyzed data within and across five clinical symptom severity categories to examine for QOL constructs, impact on everyday life, understanding of disease, and desired treatment. Results demonstrate that individuals do not fully understand PAD diagnosis or its implications (e.g., “[I] have never heard of it. Do I have that?”). Disease-specific knowledge was prevalent among patients experiencing lower extremity amputation but those suffering from wounds or gangrene had limited understanding. Furthermore, patients’ descriptions of QOL conflicted with the conceptualization of QOL in clinical practice and research. That is, many participants describe QOL based on activities they are capable of performing despite limitations. Results demonstrate the need for integrating gerontological knowledge into clinical care to improve quality of care for older adults.

REALITY OR A DREAM: BARRIERS AND FACILITATORS FOR NURSING ASSISTANTS PURSUING A NURSING CAREER

Stephanie Trotter, and Leah Richardson, *University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*

Certified nursing assistants (CNAs) serve a critical role in the care of older adults. However, CNAs often experience significant professional and personal burdens related to caregiving work. Professionally, CNAs experience exorbitant workplace stress (e.g., physical injury, burnout, emotional exhaustion, staffing shortages, turnover). Personally, CNAs may have only a high school education, are subjected to low-paying jobs, and little opportunity for career advancement. Further, CNAs are disproportionately of minority race. Clearly, CNAs are negatively impacted by many social determinants of health. Ultimately, these burdens negatively impact older adults’ care provision and quality of life. Transitioning to a nursing career may alleviate some of these complex problems, but this has scantily been explored. A qualitative descriptive study was designed to 1) identify interest in a nursing career, and 2) explore perceived barriers and facilitators of transitioning into a nursing profession. CNAs from nursing facilities participated in private, semi-structured interviews. Recorded interviews (n = 6) were transcribed verbatim. Preliminary thematic analyses yielded two overarching themes: The Dream and The Reality. Rich subthemes began emerging from both overarching themes.

Example subthemes from The Dream were: family legacy in healthcare, and finding purpose. Example subthemes from The Reality were: versus (CNAs vs. nurses; nurses vs. nursing care), and work-life balance. These preliminary findings suggest that CNAs express desire in becoming a nurse, although a range of personal and professional barriers and facilitators exist. Making the nursing dream become reality may improve CNAs’ social determinants, workplace outcomes, and resident outcomes, but further exploration is warranted.

RELATIONSHIP BETWEEN SEVERITY OF COMORBIDITIES AND SELF-PERCEPTIONS OF AGING

DaJung Chang, *Miami University, Oxford, Ohio, United States*

An older adult with negative self-perceptions of aging (SPA) can lead to lower self-rated health and a higher risk of mortality. To stay a positive SPA, keep a healthier status is very important. However, evidence also proved that health conditions, like a physical limitation, could predict the level of SPA. Older adults usually have a higher prevalence rate of chronic diseases than the younger population, which can adversely impact them. The purpose of this study is to determine the relationship between the severity of comorbidities and the change of SPA during a time. I examined data in 7,034 people from the 2012 wave Health and Retirement Study (HRS) and followed the respondents who have answer the SPA scale in the leave-behind questionnaire in 2016. The generalized estimating equation was used to analyze the relationship between the severity of comorbidities and SPA in different waves. To measure the severity of comorbidities, a reduced index of the comorbidities severity scale (CmSS) was created to collect the health condition from HRS. Results statistical model shows that an individual with more severity of comorbidities may have a more negative SPA. However, the relationship does not follow through with the times. These findings enhance the previous study that there are relationships between severity of comorbidities and SPA. The benefit of this study is to use a different measurement to identify the severity of comorbidities and extend to more in-depth research.

REPRESENTATION OF OLDER ADULTS IN COVID-RELATED NEWSPAPER COVERAGE

Mijin Jeong,¹ Sarah Jen,² Hyun Kang,¹ Michael Riquino,¹ and Jaime Goldberg,³ 1. *University of Kansas, LAWRENCE, Kansas, United States*, 2. *University of Kansas, Lawrence, Kansas, United States*, 3. *University of Wisconsin-Madison, Madison, Wisconsin, United States*

Based on clinical and epidemiological evidence, COVID-19 infection can occur in people of all ages; however, the media typically focuses its attention on the vulnerability of older adults and individuals with chronic illnesses. This study aims to explore the representation of older adults during the first month of the pandemic in the U.S. by comparing the narratives of older adults and younger adults in national media sources. A systematic search identified 115 articles published in four major newspapers in the U.S. included USA Today, The New York Times, Los Angeles Times, and The Washington Post between March 11 and April 10, 2020 in which older adults and younger adults were quoted on topics related to the intersection of COVID-19 and aging. Quotes

were inductively reviewed using thematic content analysis. In 115 articles, there were 265 quotes from older adults (n=104, 39%) and younger adults (n=161, 61%). When comparing patterns that were common or distinctive between older and younger individuals quoted, three key themes emerged: 1) impacts of COVID-19 on older adults and resulting vulnerability, 2) debated perspectives over the value of older adults' lives, and 3) a counternarrative of resiliency among older adults. This study provides the opportunity to understand how the pandemic may impact representations of older adults and findings emphasize the importance of voice among older adults to combat ageist messaging and promote counternarratives to assumptions of vulnerability. Also, it suggests for policymakers and practitioners to insight into how the representation of older adults is disseminated by media.

RESIDENTIAL CARE IN CALIFORNIA: SPATIAL AND TEMPORAL TRENDS IN FACILITY DEVELOPMENT AND CARE CAPACITY

Stephen Frochen,¹ Jennifer Ailshire,² Seva Rodnyansky,³ and Connor Sheehan,⁴ 1. *VA Greater Los Angeles Healthcare System, Costa Mesa, California, United States*, 2. *University of Southern California, Los Angeles, California, United States*, 3. *Occidental College, Los Angeles, California, United States*, 4. *ASU, Tempe, Arizona, United States*

The U.S. is aging, and the older adult population and number of long-term care services are growing but not at corresponding rates and concentrations depending on location. Insufficient research has analyzed residential care at the neighborhood or city level of analysis, where geographical trends in growth often reveal notable patterns of long-term care unobserved at county and state levels of analyses. We merged the California Department of Social Services Residential Care for the Elderly Dataset with census place and tract data to chart the growth of facilities and beds per older adults in all of California and its three largest cities, including 805 facilities licensed from 1996 to 2015. During the study timeframe, residential care steadily increased in California by the number of facilities and beds relative to older adults. However, due to a consistently increasing older adult population, the Cities of San Diego and San Jose experienced gradual and intermittent decline in capacity per older adults, respectively, even as they added many beds to their inventories from the sporadic development of large assisted living and continuing care retirement communities. Additionally, San Jose and Los Angeles exhibited the most overlap in mapping densities of facility development and oldest old adults, with San Diego showing less intersection in cartographic analysis. Understanding facility development and care capacity trends can help local agencies and

jurisdictions in the U.S. and other countries discern whether planning policies and other geographical and development factors appropriately encourage the development of residential care and other long-term care facilities.

SAFETY AND TOLERABILITY OF AN AD26.RSV.PREF-BASED VACCINE IN A PHASE 2B STUDY IN OLDER ADULTS

Ann Falsey,¹ Kristi Williams,² Efi Gymnopoulou,³ Stephan Bart,⁴ John Ervin,⁵ Els De Paepe,³ Esther Heijnen,⁶ and Christy Comeaux,⁶ 1. *University of Rochester School of Medicine, Rochester, NY, USA, Rochester, New York, United States*, 2. *Janssen Research and Development, Spring House, PA, USA, Spring House, Pennsylvania, United States*, 3. *Janssen Infectious Diseases, Beerse, Belgium, Beerse, Antwerpen, Belgium*, 4. *Optimal Research, LLC/Synexus Clinical Research/AES, Woodstock, MD, USA, Rockville, Maryland, United States*, 5. *AMR Kansas City, Kansas City, MO, USA, Kansas City, Missouri, United States*, 6. *Janssen Vaccines & Prevention BV, Leiden, The Netherlands, Leiden, Zuid-Holland, Netherlands*

Respiratory syncytial virus (RSV) may cause severe lower respiratory tract disease in older adults and there is currently no approved vaccine. We assessed the safety and reactogenicity of an Ad26.RSV.preF-based vaccine in a randomized, double-blind, placebo-controlled Phase 2b proof-of-concept trial in adults aged ≥ 65 years (CYPRESS; NCT03982199). Prior to the RSV season, participants were randomized 1:1 to receive an Ad26.RSV.preF-based vaccine or placebo. Solicited adverse events (AEs; fatigue, headache, nausea, myalgia, fever, injection site reactions) and unsolicited AEs were assessed from time of vaccination to Day 8 and Day 29, respectively, in a safety subset of 695 participants (vaccine, n=348; placebo, n=347). All participants were followed for serious AEs (SAEs) until the end of the RSV season or 6 months after vaccination, whichever occurred later. A total of 5728 participants were randomized and received vaccine or placebo (n=2891 in each group). In the safety subset, the frequency of solicited AEs and Grade ≥ 3 solicited AEs was 51.4% and 3.2% in the vaccine group and 20.2% and 0.6% in the placebo group, respectively. The most frequent solicited AEs in the vaccine group were fatigue, myalgia, headache, and injection site pain/tenderness. The rates of unsolicited AEs and Grade ≥ 3 unsolicited AEs were similar between the vaccine (16.7% and 1.7%) and placebo (14.4% and 1.4%) groups. In the overall study population, the rate of SAEs was similar between groups (vaccine, 4.6%; placebo, 4.7%); none were considered related to the vaccine. The Ad26.RSV.preF-based vaccine was safe and well tolerated in adults aged ≥ 65 years.

SELF- AND INFORMANT-REPORTED LONELINESS AND COGNITIVE FUNCTION: EVIDENCE FROM THREE HCAP STUDIES

Ji Hyun Lee,¹ Martina Luchetti,² Amanda Sesker,² Damaris Aschwanden,³ Angelina Sutin,² and Antonio Terracciano,⁴ 1. *University of Michigan, Ann Arbor, Michigan, United States*, 2. *Florida State University College of Medicine, Tallahassee, Florida, United States*, 3. *Florida State University, Tallahassee, Florida, United States*, 4. *FLORIDA STATE UNIVERSITY, Florida State University, Florida, United States*

Loneliness is defined as a distressing feeling that arises from the discrepancy between one's desired and perceived social relationships. Theorists have posited that loneliness involves affective, cognitive, and behavioral components that can be noticed by close family or friends. Little is known about whether social withdrawal, a behavioral marker of loneliness observed by knowledgeable others, shares similar associations with cognition as self-reported loneliness. The present study examined whether self-reported and informant-rated loneliness are related to cognitive function in older adulthood. Data come from Harmonized Cognitive Assessment Protocol subsample included in three national aging studies from the US (HRS; N = 2,821, Mage = 75.8), England (ELSA; N = 896, Mage = 73.6), and India (LACI-DAD; N = 2,994, Mage = 69.3). Respondents reported on 1-item loneliness and informants rated the respondent's withdrawal behavior. Regression models were used to analyze the association between both measures of loneliness and cognition, controlling for respondent (age, gender, education, race/ethnicity) and informant (age, gender, education, spouse, known years, frequency of contact) covariates. Meta-analysis showed that both respondent-reported and informant-rated loneliness were independently associated with lower cognitive functioning (memory, speed-attention-executive, visuospatial ability, and fluency) and global cognition (MMSE). The associations between observed withdrawal and cognition did not vary by informant-level characteristics nor the respondent's cognitive impairment status. The present study indicates that withdrawal behavior observed by informants is associated with cognitive function, supporting psychosocial observations provided by knowledgeable others can be utilized in detecting cognitive function.

SEX DIFFERENCES IN CARDIOVASCULAR MARKERS AND BDNF BETWEEN CEREBRAL PALSY AND MILD COGNITIVE IMPAIRMENT

Ted Ng,¹ James Carollo,² Alex Tagawa,³ ZHAOXING PAN,⁴ and Patricia Heyn,⁵ 1. *ASU, Phoenix, Arizona, United States*, 2. *University of Colorado Anschutz Medical Campus, University of Colorado Anschutz Medical Campus-Center for Gait and Movement Analysis (CGMA), Colorado, United States*, 3. *University of Colorado Anschutz Medical Campus, Denver, Colorado, United States*, 4. *University of Colorado Anschutz Medical Campus, Aurora, CO, Colorado, United States*, 5. *University of Colorado Anschutz Medical Campus, Arvada, CO, Colorado, United States*

Adults with cerebral palsy (CP) have higher risk of developing geriatric syndromes. Mild cognitive impairment

(MCI) is an intermediate stage between healthy aging and dementia, often co-morbid with cardiovascular disease (CVD). We recently showed an "accelerated aging model", where CP shares similar CVD risk factors with MCI, potentially accounting for CP's increased risk of dementia. In this study, we further examined sex differences between CP and MCI (aim 1) and within CP (aim 2). From an accredited clinical motion analysis laboratory at Children's Hospital Colorado (CP) and a university in Singapore (MCI), we recruited 72 adults with CP [mean (SD) of age=20 (5.3), Sex: men=47.2% and women=52.8%] and MCI [mean (SD) of age=71.28 (6.03), Sex: men=29.2% and women=70.8%]. We analyzed blood Pressure (BP), Framingham Heart Study Score (FHSS), and brain-derived neurotrophic factor (BDNF). Compared to MCI, women with CP had lower BDNF ($\beta=-3.550$, 95% CI=-5.659 to -1.441, $p=0.001$), while men with CP had lower diastolic BP ($\beta=-28.204$, 95% CI=-52.148 to -4.260, $p=0.022$). Both women and men with CP also had lower FHSS, compared to MCI ($\beta=-2.515$, 95% CI=-3.721 to -1.309, $p<0.001$; $\beta=-3.724$, 95% CI=-5.561 to -1.888, $p<0.001$, respectively). Women in the CP cohort showed lower FHSS ($\beta=-0.172$, 95% CI=-0.310 to -0.033, $p=0.016$). We found sex-related differences in BDNF and CVD markers. Comparing across and within cohorts, although having lower BDNF levels, women with CP had better FHSS. These findings support our accelerated aging hypothesis, and further suggest sex differences in aging-related risk factors in CP, supporting sex-related precision medicine approach.

SINGLE CELL ANALYSIS REVEALS STOCHASTIC CELL-TO-CELL VARIATION IN STRESS RESPONSE AND SENEESCENCE PROGRAM

Nikolay Burnaevskiy,¹ and Alexander Mendenhall,² 1. *University of Washington, University of Washington, Washington, United States*, 2. *University of Washington School of Medicine, University of Washington School of Medicine, Washington, United States*

Cells have various means to respond to molecular stress. Upon stress, proliferating cells can adopt different fates, e.g. commit to apoptosis, go into senescence or recover from stress and resume proliferation, depending on severity of the stress. Proper balance between these modes of response is critical for maintaining tissue homeostasis with age, as both exacerbated and insufficient response can result in pathology. Remarkably, even genetically identical cells of the same type in the controlled environment can exhibit a spectrum of responses to the same stress challenge. We hypothesized that analyzing response of individual cells in controlled environment can help better understand the mechanisms that ensure a balanced response to molecular stress. We used large scale single cell RNA-sequencing to analyze response of individual human fibroblasts to oxidative stress. Consistent with various fates adopted by individual cells upon stress, we observed different transcriptional signatures, that correspond to those fates. Surprisingly, when we specifically analyzed β -gal+ senescent cells, we still observed transcriptional heterogeneity, with only a subset of cells exhibiting pro-senescent transcriptional signature (e.g. activated p53 and TNF- α pathways) while another subset exhibits a gene expression signature of senescent-like arrest. Hence, we find that in addition to

known stress-related fates (apoptosis, senescence, recovery) senescence-like response is heterogeneous with only subset of cells exhibiting expected pro-senescent gene expression signature. Further characterization of heterogeneity of stress response and senescent-like fates will help better understand the mechanisms of homeostatic control in the face of molecular stress and aging.

STRATEGIES TO MAINTAIN SKILLED NURSING FACILITY STAFFING DURING COVID: ADMINISTRATOR PERSPECTIVES

Amy Meehan,¹ Renee Shield,¹ Joan Brazier,¹ Emily Gadbois,¹ and Caroline Madrigal,² 1. *Brown University, Providence, Rhode Island, United States*, 2. *Providence VA Medical Center, Providence VA Medical Center, Rhode Island, United States*

As COVID-19 has resulted in a skilled nursing facility (SNF) staffing crisis, administrators attempt to maintain adequate staffing and stem decreasing patient census levels. We conducted four repeated interviews to date (n=130) at 3-month intervals with administrators from 40 SNFs in eight diverse healthcare markets across the United States. We used thematic analysis to examine their perspectives over time, including the perceived impact on staffing. Results include: 1) the impact of COVID-19 on staffing levels, and 2) strategies used in response to this crisis. Staffing levels have decreased throughout the pandemic, and struggles to maintain adequate staffing levels and patient census numbers have continued as the pipeline of potential new staff constricts. Facilities turned to agencies, many for the first time. Since agencies offer higher salaries, staff are drawn away from employment by SNFs, leading to a cycle of wage wars, and agencies are also challenged to provide staff. SNF administrators describe their responses to this crisis, such as flexible schedules, increased paid time off, sharing of non-direct-patient-care tasks, financial incentives (referral, sign-on, “no-call out”, and other general bonuses); wage analyses, and enhanced employee benefit packages. Some hire recruitment specialists, collaborate with nearby administrators, use creative advertising, or work with local schools. The vaccine mandate worries administrators; as one stated: “I can't afford to lose one person, let alone 20 because of this mandate...”. Given the dwindling pool of potential employees, we present NH administrators' strategies to attract and retain staff.

STRUCTURAL RACISM IS ASSOCIATED WITH ASSISTED LIVING LOCATION

Lindsey Smith,¹ Paula Carder,² Kali Thomas,³ Robin Baker,¹ and Neal Wallace,¹ 1. *Oregon Health & Science University - Portland State University School of Public Health, Portland, Oregon, United States*, 2. *OHSU-PSU School of Public Health, Portland, Oregon, United States*, 3. *Brown University, Brown University/Providence, Rhode Island, United States*

Our objective was to measure the association between structural racism, a previously unmeasured but theoretically causal factor, and assisted living communities (ALCs) location as fewer ALCs are located in counties with a greater percentage of the population reported as Black (PPB). We used a recently developed measure of structural racism—the racial opportunity gap (ROG), which compares the economic

mobility of Black and White people who grew up in the same area with parents who had similar incomes. We estimated a multilevel mixed-effects bivariate regression model to examine the factors contributing to the presence of ALC. We relied on state and county random effects. The likelihood of an assisted living being located in a census tract in 2019 was significantly positively associated with the percent of the population over the age of 65 (OR=150.1573, $p<0.001$), the PPB (OR=2.9916, $p=0.004$), and higher median incomes (OR=1.0, $p<0.001$). In contrast, rurality (OR=0.5656, $p<0.001$), unemployment rates (OR=0.0288, $p<0.001$), and census tracts that have a high PPB in addition to a high county ROG (OR=.0058, $p=0.0137$) are all associated with a lesser likelihood of an ALC. The interaction coefficient between the ROG and PPB reverses the previously documented negative association between the PPB and ALC presence. This result empirically supports the premise that structural racism, not population race alone, is a negative determinant of where an ALC is located within a county.

SUCCESSFUL AGING: MEMORY AND SMART TECHNOLOGY IMPLICATIONS.

Neyda Ma. Mendoza-Ruvalcaba,¹ Elva Dolores Arias-Merino,² Karla Patricia Vázquez Núñez,³ and Marlene Alvarado Rodriguez,⁴ 1. *Universidad de Guadalajara CUTONALA, Guadalajara, Jalisco, Mexico*, 2. *Universidad de Guadalajara, Zapopan, Jalisco, Jalisco, Mexico*, 3. *Universidad de Guadalajara, Doctorado en Investigación Multidisciplinaria en Salud, Universidad de Guadalajara, Jalisco, Mexico*, 4. *Universidad de Guadalajara, Maestría en Gerontología, Universidad de Guadalajara, Jalisco, Mexico*

The cognitive functioning as a general measure, is a criterion commonly used to define and operationalize successful aging (SA). The aim of this study is to analyze the specific role of memory (objective and subjective) and its relationship with the use of smart technology (ST) and SA. (Project-Conacyt-256589) Population based, random sample included n=453 community-dwelling older adults 60-years and older (mean age=72.51, SD=8.11 years, 59.4% women). Memory was assessed through working memory (Digit Span Backward WAIS-IV), episodic memory, metamemory (self-report), subjective memory, and learning potential (RAVLT). SA was operationalized as no important disease, no disability, physical functioning, cognitive functioning, and being actively engaged. Participants were asked if they use cellphone, computer, or tablet. Pearson's correlation test and linear regression models were performed. In total 11.2% were successful agers. 53.6% used cellphone, 14% computer, 8% tablet, 44.1% any device. Results show significant correlation between SA and subjective memory, learning potential and the use of ST. Results of the multiple regression analysis emerged on a significant model using the entered method: $F=26.05$, $p>.000$, explaining 21.4% of the variance of SA. Although objective memory measurements were no significant for SA, all memory measurements were related to the use of ST. Knowledge generated by this study reveals the specific role of the metamemory on the SA, underlining the relevance of subjectivity on aging. We need to reflect about the limitations of older adults to access to a digital world in order to achieve a SA.

SYSTEMS AGING CLOCK: A NOVEL EPIGENETIC AGING CLOCK MODELED FROM ORGAN & BODILY FUNCTION BASED MORTALITY INDICES

Raghav Sehgal, and Morgan Levine, *Yale University, New Haven, Connecticut, United States*

A diverse array of aging clocks, derived from a variety of omics data and clinical biomarkers, have been developed to describe aging and predict age-related disease. As such, these biomarkers are particularly applicable for use in observational studies, basic science and clinical trials focused on tackling biological aging. However, ongoing research suggests significant heterogeneity in aging, with deterioration and disease occurring in different organ systems or functional domains at various rates across individuals. Existing aging clocks only measure heterogeneity in the degree of aging, not in the manner of aging (e.g. different organ systems or functional domains). We hypothesize these unique trajectories exist and that they can be captured using a systems based approach. In our work, using clinical chemistry biomarkers from participants in the Health and Retirement Study (HRS), Framingham Heart study (FHS) and Women's Health Initiative (WHI), we modeled unique epigenetic aging trajectories from distinct groups of biological processes (such as Immune function, metabolic function, hepatic function, cardiac function, renal function and more). Interestingly, these biological system specific scores when combined gave an aging clock with superior mortality prediction than any published aging clock. We further validate the system aging scores and aging clock in different clinical studies to show the added advantage of such a measure, such as the fact that people with similar epigenetic age may have very different system scores. Overall, this method introduces the potential for quantitative and multi-dimensional, personalized aging scores that are indicative of an individual's disease and disorder risk.

THE BUFFERING EFFECT OF RESILIENCE ON THE SOCIAL CONSEQUENCES OF COVID IN OLDER WOMEN

Nacia Goldberg, Dawn Carr, Miles Taylor, and Natalie Sachs-Ericsson, *Florida State University, Tallahassee, Florida, United States*

Prior to the pandemic, public health experts argued that loneliness was among the most significant threats facing women's health and wellbeing. As the COVID-19 pandemic brought our social lives to an abrupt pause in March, 2020, older adults were encouraged to remain isolated from friends and family. Social distancing guidelines led many older people to decrease social interactions with others. Using a community-based longitudinal study of women age 60+, we examined how changes in feelings of social connections with others influenced loneliness in October 2020 relative to prior to the pandemic (in September 2018). Our previous research has shown that psychological resilience decreases the negative consequences of major life stressors in later life. We hypothesized that women with high social consequences of the pandemic would experience increased loneliness, but resilience would buffer these effects. In line with our hypotheses, results showed that those who reported significant declines in social connectedness with others during the pandemic (i.e., high social consequences) experienced significant increases

in loneliness ($\beta=0.125$; $p<0.001$). Resilience, alternatively, was significantly associated with decreased loneliness ($\beta=-0.05$; $p<0.05$), and buffered the social consequences of the pandemic. That is, as resilience increased, the social consequences of COVID-19 significantly declined ($p<0.01$), and resilience attenuated the negative consequences of high levels of social consequences of COVID-19 on loneliness, while those with high social consequences and low resilience experienced significant increases in loneliness in association with the pandemic. Based on our findings, we discuss potential clinical implications for resilience-based interventions for older adults.

THE IMPACT OF RETIREMENT RESOURCES ON U.S. OLDER FEMALE WORKERS' RETIREMENT TIMING: THEORY OF PLANNED BEHAVIOR MODEL

Hansol Kim,¹ David Ekerdt,² Tamara Baker,³ Amber Watts,² Tracey LaPierre,² and Yan Bing Zhang,² 1. *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*, 2. *University of Kansas, Lawrence, Kansas, United States*, 3. *University of North Carolina, Chapel Hill School of Medicine, University of North Carolina at Chapel Hill (School of Medicine), North Carolina, United States*

For older workers, having a retirement plan is important for a successful transition. Social awareness of the problems encountered by older women during retirement remains low. Women have limited retirement resources due to their unequal work experience, and older women with access to fewer retirement resources often postpone their retirement. This research examined how the timing of older women's retirement was influenced by their retirement resources as well as their marital status. The study used 2014 HRS and RAND data, and collected sample of women aged 50-62 years old who worked either full or part time ($n=3,593$). Respondents were female (56%), white (63%), married (70%), and working full time (82%). Guided by the theory of planned behavior (TPB), multiple regression analysis examined gender differences in predicting older adults' retirement timing. TPB included three sub factors: attitudes toward retirement, subjective norm, and perceived behavioral control. Logistic regression analyzed the effects of respondents' expectations of retirement (i.e., with vs without expected timing). The findings indicated that the TPB model works similarly for men and women but there is a difference according to marital status. Unmarried women are less likely to have accumulated financial resources and more likely to anticipate a later retirement (1.4 years) than married women and are also less likely to set an expected timing for retirement ($p<0.05$). Such a robust research agenda would provide key information for government agencies and policymakers and contribute to the development of retirement planning models or retirement education programs for older women.

THE IMPACTS OF SOCIO-ECONOMIC CHALLENGE ON LONG-TERM PHYSICAL AND MENTAL HEALTH IN RETIREMENT AGE

ILAN KWON,¹ sojung park,² BoRin Kim,³ and ByeongJu Ryu,⁴ 1. *Our Lady of the Lake University, San Antonio, Texas, United States*, 2. *Washington university, St.Louis, Missouri, United States*, 3. *University of New Hampshire, University of New Hampshire, New*

Hampshire, United States, 4. Brown School, Washington University in St. Louis, St. Louis, Missouri, United States

Despite consistent evidence on the negative effect of social and economic challenges on health, little is known about the pattern of economic difficulties people experience and the impact of those challenging patterns on long-term health in later life. This study used the national data, Mid Life in the United States (MIDUS 3 in 2013-2014), to identify the different patterns of socio-economic challenges that older Americans (50-64 ages old) experienced during the Recession in 2008 and to examine the impact of past challenging experiences on physical and mental health in their later life. Socio-economic challenges included twenty-six items such as losing or moving a job, missing rent, selling or losing a home, bankruptcy, having debts, and cutting spending. We conducted the latent class analysis and regression while controlling other social determinant factors (e.g., education, employment status, poverty, etc.). The latent class analysis result found five patterns during the Recession: people who experienced various difficulties during the Recession, who moved their jobs, who experienced financial difficulties, who bought a home with decreased debts, and who experienced no difficulty. Compared to people with no challenging experience, those who needed to move their jobs but could make debt off during the Recession reported physically healthier, but not mentally healthier in later life. Interestingly, among this group, women reported more long-term physical health problems than men. The findings suggest the close connection between physical and mental health and the importance of long-term care for mental health among older adults in recovering from socio-economic challenges.

THE MORTALITY OF OLDER ADULT INPATIENTS WITH KIDNEY CANCER DURING THE PANDEMIC: A RETROSPECTIVE COHORT STUDY

Kendall Brune,¹ Cheng Yin,² Liam O'Neill,³ and Rongfang Zhan,² 1. *Meharry Medical College, Nashville, Tennessee, United States*, 2. *University of North Texas, Corinth, Texas, United States*, 3. *University of North Texas, University of North Texas, Texas, United States*

Background: Elderly patients are a vulnerable group during the Covid-19 pandemic, especially those with cancer. Our study aims to identify how Covid-19 impacts elderly inpatients with kidney cancer and determine risk factors associated with increased mortality. Methods: Our retrospective cohort study utilized the PUDF dataset and included inpatients over 60-year-old, diagnosed with kidney cancer, and hospitalized within 30-day. Person's Chi-Square was used to measure the differences between survivors and non-survivors, and the Mann-Whitney test was for non-normality distribution for continuous variables. Then, a binary logistic regression was employed to identify the association between independent variables and mortality. Results: Five hundred and twenty-two patients were included in the study, of which 7 (1.4%) died during hospitalization. According to the univariate analysis and Mann-Whitney test, expired patients were more likely to experience older age ($p = 0.005$), longer length of stay ($p = 0.009$), ICU ($p = 0.012$), HMO Medicare Risk ($p = 0.005$), Covid-19 ($p < 0.001$), paralysis ($p < 0.001$), and higher illness severity ($p < 0.001$). The binary logistic regression revealed that older age (OR = 1.120, 95%

CI: 1.004-1.249, $p = 0.042$) and the SOI (OR = 4.635, 95% CI: 1.339-16.052, $p = 0.016$) had significantly high odds of mortality. Conclusion: The retrospective cohort study reveals that although Covid-19 was not a predictive factor associated with increased mortality, there was a statistically significant difference between the survivor and non-survivor groups. Further studies need to assess its association with kidney cancer or other various types of cancer.

THE MYTH OF CARE COORDINATION: WHETHER PROFESSIONAL CARE COORDINATION IMPROVED OLDER ADULTS' HEALTH OUTCOMES?

Kedong Ding, *Case Western Reserve University, Cleveland, Ohio, United States*

Background: Current evidence on the effects of Care Coordination (CC) on older adults' well-being and health service utilization is inconsistent. Previous studies are mostly limited to regional data and focus mostly on nurse-led CC instead of layperson Care Coordinators like family caregivers. This study explores the effects of having CC in a national sample of U.S. older adults and whether the coordinators' professionalism impacts the effect of having CC on multidimensional health outcomes (Health outcomes were conceptualized as physical health, healthcare utilization, and care encounters). Methods: Data were from the 2016 and 2018 waves of the Health and Retirement Study (HRS) ($n=1,372$). Multivariate regression models were used to examine the effects of CC on multidimensional health outcomes in 2016 and the longitudinal effects of having CC. We also tested the effect of Care Coordinators' professionalism on the multidimensional health outcomes. All models controlled for sociodemographic characteristics and health status. Results: Findings suggest that having CC doesn't have a positive effect on older adults' health outcomes. Having CC was associated with an increased number of acute diseases ($\beta = 0.16$, $p < .001$) and nonacute diseases ($\beta = 0.21$, $p < .01$) in longterm. The results regarding cross-sectional effects show that receiving care from a Coordinator was related to increased health service utilization. Participants with professional Care Coordinators were more likely to report receiving person-centered care (OR=1.60, $p < .05$). Conclusion: This study demonstrates the limited effects of CCs on older adults' physical health outcomes, and emphasized the importance of care coordinators' qualifications.

THE RELATIONSHIP BETWEEN COVID 19 ANXIETY AND DEMENTIA CAREGIVERS BURDEN AND SUFFERING

Kaitlyn Lucas,¹ Eleanor Batista-Malat,² Seho Park,³ Shelly Johns,⁴ Nicole Fowler,⁵ and Katherine Judge,⁶ 1. *Cleveland State University, Westlake, Ohio, United States*, 2. *Indiana University School of Medicine, Regenstrief Institute, Indiana, United States*, 3. *Indiana University School of Medicine, Department of Biostatistics, School of Medicine, Indiana, United States*, 4. *Indiana University School of Medicine, Center for Health Services Research, Indianapolis, Indiana, United States*, 5. *Indiana University School of Medicine, IU Center for Aging Research, Indianapolis, Indiana, United States*, 6. *College of Sciences and Health Professions, Cleveland State University, College of Sciences and Health Professions, Ohio, United States*

The impact of COVID-19 on dementia caregivers is gaining new interest. It is unknown how the pandemic has impacted caregivers' burden and existential suffering. Analyses were performed on data for dementia caregivers (n=89) enrolled in the Indiana University Telephone Acceptance and Commitment Therapy for Caregivers (TACTICs) pilot trials. Individuals were primary caregivers of a family member with dementia and had clinically significant anxiety measured by a GAD-7 score >10 or between 5-9 with reported interference in life. COVID-19 anxiety was measured using the NIH CoRonavIRuS Health Impact Survey (CRISIS) questions. Caregivers were on average 55.2 years of age with 56.2% being child or child-in-law, 71.9% were white and 24.7% were Black. Mean burden scores, measured by the Zarit Burden Index, were higher (44.29) compared to means reported across the literature (26.7) indicating the sample experienced higher than normal levels of burden. Mean existential suffering scores measured by the subscale of Experience of Suffering Scale were lower (9.37) compared to means across the literature (11.5) indicating that overall participants experienced lower levels of existential suffering compared to those in previous studies. A significant relationship was found between COVID-19 anxiety and burden levels ($x^2 = 9.07, p < 0.05$), with higher levels of COVID-19 anxiety associated with greater burden. A non-significant relationship was found between COVID-19 anxiety and existential suffering ($x^2 = 5.99, p = 0.11$). Results highlight the impact of COVID-19 anxiety as an external stressor on dementia caregiving, and the importance of considering context of external stressors when implementing intervention protocols for caregivers of individuals with dementia.

THRIVING-IN-PLACE: EXAMINING THE IMPACT OF INTERGENERATIONAL LIVING IN THE TORONTO HOMESHARE PROGRAM

Raza Mirza,¹ Melissa Macri,¹ Deirdre Kelly-Adams,¹ Carley Moore,¹ Andrea Austen,² Jacalyn Tanner,³ Jessica Hsieh,¹ and Christopher Klinger,¹ 1. *University of Toronto, Toronto, Ontario, Canada*, 2. *City of Toronto, City of Toronto, Ontario, Canada*, 3. *National Initiative for the Care of the Elderly (NICE), Toronto, Ontario, Canada*

Most global cities, like Toronto, have rapidly aging populations who want to remain in homes and communities of their choice. Concurrently, seniors face vulnerabilities associated with low income, ageism, social isolation and loneliness. These vulnerabilities inhibit many seniors' desires to age-in-place. The Toronto HomeShare Program, an intergenerational homesharing program facilitates aging-in-place by matching seniors with post-secondary students. The program, with an implementation focus and a research study, was developed to address and understand the needs of seniors seeking assistance, light supports and companionship at home, in exchange for reduced-rent housing for students. A mixed methods research design was employed. Seniors and students (n=22) completed a 167 question survey (n=22) and in-depth interviews (n=18). Quantitative data yielded descriptive statistics and qualitative data was subject to thematic content analysis. Participants agreed that homesharing programs could address risk for social isolation (95%), the need to move from their community (96%), and reduce risks of economic and social exclusion for young and old (97%).

From the qualitative data, six benefits were apparent for all participants: (1) reduced social isolation and loneliness, (2) increased intergenerational exchange, (3) increase financial security, (4) household assistance, (5) increased general wellbeing; (6) enhanced companionship/safety. In 2020, Toronto HomeShare (now Canada HomeShare) was recognized by the World Health Organization as an age-friendly best practice, and has been scaled nationally in 16 cities. Intergenerational homesharing programs could be a catalyst for policy and cultural reform and to support older adults to not only remain in their communities, but to thrive-in-place.

TOO CLOSE FOR COMFORT? COVID-19-RELATED STRESS AMONG OLDER COUPLES AND THE MODERATING ROLE OF CLOSENESS

Kira Birditt, Angela Turkelson, and Angela Oya, *University of Michigan, Ann Arbor, Michigan, United States*

Married and cohabiting couples have important influences on one another's stress and well-being. Pandemic-related stress may influence the extent to which couples' stress levels are coregulated. This study examined the experience of nonspecific stress and pandemic-related stress and the moderating role of closeness among couples aged 50 and over in which at least one member had hypertension. A total of 30 couples reported their feelings of closeness to one another in a baseline interview and their feelings of nonspecific stress and pandemic-related stress every three hours for 5 days. There was no difference in closeness and nonspecific stress between husbands and wives. Wives reported greater pandemic-related stress than husbands. Actor-partner interdependence models revealed that wives' nonspecific stress predicted husbands' nonspecific stress ($b = 0.17, SE = 0.04, p < .001$) and that husbands' nonspecific stress predicted wives' nonspecific stress in each three hour period ($b = 0.19, SE = 0.04, p < .001$) and these associations were not moderated by closeness. Coregulation in pandemic-related stress among husbands and wives was moderated by wives' feelings of closeness such that when wives' feelings of closeness were lower, greater husband pandemic-related stress predicted lower pandemic-related stress for wives ($b = -0.16, SE = 0.07, p < .05$) whereas when wives' feelings of closeness were higher, greater husband pandemic-related stress predicted greater pandemic-related stress for wives ($b = 0.22, SE = 0.09, p < .05$). These findings indicate that closeness may have detrimental effects especially when considering emotional coregulation in couples regarding the pandemic.

TREATING CAREGIVER GRIEF WITH NARRATIVE THERAPY

Tara Matta, *University of South Florida, Tampa, Florida, United States*

Dementia, a devastating neurodegenerative disease with over 10 million new diagnoses each year, is characterized by many symptoms including memory loss. Individuals with memory less experience changes in mood, personality, behavior, cognition and activities of daily living which affect their daily lives. These monumental life shifts often occur rapidly, leaving caregivers unprepared to deal with the changes. Caregivers face a unique situations navigating anticipatory grief and changes in their relationships with their loved ones. Current psychological intervention for

caregivers includes utilization of cognitive-behavioral therapy and psychoeducation. More recently, intriguing research has emerged regarding the efficacy of narrative therapy for couples where one partner experiences memory loss. However, treating the anticipatory grief component specifically for caregivers has been largely overlooked in these studies. Narrative therapy revolves around identifying the current story that caregivers utilize as their cognitive framework, helping to find alternative plotlines and to process their newly-built cognitive framework. It involves externalizing the problem (in this case, dementia) and locating strengths that the caregiver and their care receiver share to “fight” the problem. Insights from both the current literature and the field have demonstrated a promising outlook on the use of narrative therapy. Such insights imply a need for more research regarding this modality specifically for caregivers, as its core ideas can be easily disseminated to gerontologists, mental health professionals and caregivers.

USER PERCEPTIONS OF A TECHNOLOGY-BASED SOCIAL MEMORY AID FOR PERSONS WITH MEMORY CONCERNS

Brenna Horn,¹ Elizabeth Albers,² Eric Jutkowitz,³ Jessica Finlay,⁴ Lauren Mitchell,⁵ Ashley Millenbah,⁶ and Jude Mikal,² 1. *University of Minnesota/ Families and Long-Term Care Projects, Minneapolis, Minnesota, United States*, 2. *University of Minnesota, Minneapolis, Minnesota, United States*, 3. *Brown University, Brown University, Rhode Island, United States*, 4. *University of Michigan, Ann Arbor, Michigan, United States*, 5. *Emmanuel College, Boston, Massachusetts, United States*, 6. *University of Minnesota, University of Minnesota, Minnesota, United States*

People with memory concerns (PWMC) are likely to experience social withdrawal and isolation. Although assistive technologies and memory aids are available to support PWMC and their family caregivers, few have been shown to improve social engagement. This study aimed to gain perspectives of PWMC and their family caregivers on the feasibility and utility of a technology-based social memory aid. We recruited 20 dyads of people with mild to moderate memory concerns and family caregivers to evaluate Smartwatch Reminder (SR), a notification system that provides a name, relationship, and photograph of nearby social contacts to aid in recognition. Dyads viewed a demonstration of the SR prototype, and then participated in semi-structured interviews over Zoom video conferencing from June to August, 2020. Interview transcripts were analyzed using thematic analysis, with analyses completed in August 2021. Our findings indicate that participants anticipated important benefits from using the technology, and thought the technology would be easy to use. Participants perceived that the memory aid could benefit them now and in the future by alleviating socialization-related stress for both members of the care dyad; however, certain features of SR restricted the potential benefits, such as the requirement that social contacts have the SR application, and that prompts are only provided during social encounters. Our findings will inform future technology-enabled memory aid development to improve social engagement for PWMC and support family caregivers.

WITHIN-PERSON VARIATION IN EMOTIONAL EXHAUSTION AMONG CAREGIVERS FOR OLDER ADULTS

Tomoko Wakui, *Tokyo Metropolitan Institute of Gerontology, Itabashi, Tokyo, Japan*

Caregiving is everyday life for family members of older adults. Care recipients' care requirements, service usage, and caregivers' physical and emotional conditions differ day by day. Little is known how the differences and variances relate to informal caregivers' mental health. This study aimed to examine informal caregivers' day-to-day fluctuation in emotional exhaustion and discuss the within-person effects on mental health among informal caregivers. We developed the Caregiving Visualization Project toolkit (Care VIP), a software program for tracking on daily basis components of care experiences such as care task of Activity of Daily Living (ADL) and Instrumental Activity of Daily Living, service usages, and caregiving burden, as well as eight items of caregivers' emotional exhaustion. We recruited study participants between May 2018 to March 2019 who provided instrumental help to community-dwelling older adults. A total of 75 participants, who accessed the Care VIP every day by using tablets or computers and completed a one-month study, were analyzed in this study. Females comprised 80.0%, and the average age of caregivers was 52.7 years (SD=9.1). The majority were those who provided care to parents (69.3%), and those who provided to parents-in-law and spouses were 16.0% and 5.3%, respectively. The average score of the eight items on the emotional exhaustion scale, with a 4-point Likert scale, was 23.4 (SD=4.9); however, each question showed different variations. Within-person effects on mental health among informal caregivers will be discussed.

YOUR SUFFERING IS ALSO MINE: OLDER AND YOUNGER COUPLES' RESPONSES TO THE PARTNER'S UPSETTING MEMORY

Jared Isaac Cortez,¹ Stephanie J Wilson,² M. Rosie Shrout,³ and Janice Kiecolt-Glaser,⁴ 1. *Southern Methodist University, Dallas, Texas, United States*, 2. *South Methodist University, Dallas, Texas, United States*, 3. *Purdue University, Purdue University, Indiana, United States*, 4. *Ohio State University, Columbus, Ohio, United States*

Aging theories posit that older adults maximize their well-being by regulating their emotions and investing in their closest relationships. Most research has examined these mechanisms using study confederates rather than close dyads. The existing work on couples has focused on marital conflict; none has examined responses to the spouse's emotional suffering. To address this, 107 married couples ages 40-86 listened to their partner disclose an upsetting personal memory. Afterward, listeners rated their own and their partner's emotions and perspective-taking; observers reliably coded listeners' engagement and disclosers' emotional intensity. Aging theories offer competing predictions: older listeners may disengage from their partner's disclosure to avoid experiencing negative emotions. Alternatively, older adults may be more engaged and thus more reactive, given the increased investment in their close relationships. Findings showed that older listeners rated their disclosing partner as less sad compared to younger counterparts ($p < .05$). However, this effect was attenuated ($p = .077$) by observed

emotional intensity, as older disclosers exhibited less intense emotions. There were no age differences in listeners' own reactivity, perspective-taking, or observed engagement. Taken together, older adults disclosed with less emotional intensity, consistent with theory. By contrast, older listeners' ratings were validated by external coders, not driven by positivity

biases. Further, older listeners were no more or less engaged or reactive to their spouse's disclosure than younger listeners. This study highlights a context wherein social and emotional motivations are at odds. Teasing these motivations apart will help us to better understand how social-emotional processes develop across adulthood.
